Introduction

Welcome to the exciting, challenging world of automotive technology! You have selected a rewarding field of study.

Modern Automotive Technology is an easy-to-understand, up-to-date book summarizing the operation and repair of all makes and models of vehicles. The text uses a building-block approach that starts with the simple and progresses gradually to the more complex. Short sentences, concise definitions, and thousands of color illustrations will help you learn quickly and easily.

Modern Automotive Technology is a valuable reference for anyone interested in the operation, construction, and repair of automobiles and light trucks. Vehicle owners who need a general guide to automotive service will find the book both interesting and informative. Those who are preparing for a career in automotive technology will find the text a "must." Experienced technicians can use it when preparing for the ASE certification tests.

No longer can the untrained person hope to fix the modern automobile. Multiple on-board computers are now used to monitor and control the engine, transmission, suspension, braking, emission control, and other systems.

Although computer systems are discussed in almost every chapter, three chapters—Chapter 17, *Computer System Fundamentals;* Chapter 18, *On-Board Diagnostics and Scan Tools;* and Chapter 19, *Computer System Service*—explain the operation and service of these important systems in detail.

Additionally, Chapter 46, *Advanced Diagnostics,* emphasizes the use of the latest diagnostic equipment and techniques to locate engine performance problems. A few of the other topics discussed in the text include anti-lock brakes, four-wheel steering, four-valve cylinders, active suspension systems, passive restraint systems, security systems, and navigation systems.

The 2004 edition of **Modern Automotive Technology** is organized around the eight ASE automobile test areas and is correlated to the NATEF Task List. Terminology has been updated throughout the text to reflect the SAE J1930 standard.

Each automotive system is presented in two or more chapters. The first chapter explains the construction and operation of a specific system. The following chapter expands on this by detailing the troubleshooting and repair of the same system.

Type Styles Used in This Text

Various type styles are used throughout this text to emphasize words, identify important terms, and highlight figure references.

Italic type is used to emphasize words and terms. For example, the word *not* is often printed in italic type when it is imperative that an operation be avoided.

Important terms appear in ***bold-italic type.*** These terms are defined when introduced and most are listed in the Important Terms list at the end of the chapter, as well as in the Glossary at the back of the text. Study the ***bold-italic terms*** carefully.

Figure references in the body of the text and in the captions always appear in **bold type.** This makes them easy to identify.

Chapter Components

Each chapter opens with a list of *learning objectives.* These objectives identify the topics covered and goals to be achieved in the chapter. Review the objectives before reading the chapter to determine what you can expect to learn. After completing the chapter, read the objectives once more and make sure you have met each objective.

A *summary* is found at the end of each chapter. The summary highlights the material covered in the chapter. Review the summary after completing a chapter.

A list of *important terms* is also included at the end of each chapter. The terms in the list appear in the order in which they are presented in the chapter. After completing a chapter, review each term. If a term cannot be defined, review the related section in the chapter.

Conventional *review questions,* as well as a separate section of *ASE-type questions,* are presented at the end of each chapter. After completing a chapter, answer all the questions on a separate sheet of paper. This is a great way of reviewing the material presented in the chapter. It will also help prepare you for the types of questions encountered on the ASE certification tests.

Each chapter closes with a number of *activities.* These activities are automotive-related exercises that emphasize math and communication skills, as well as improve performance on the job.

Special Notices

There are a variety of special notices used throughout this text. These notices contain technical information, cautions, warnings, and references to pertinent material in other parts of the text. The notices are identified by color and by an icon.

A *note* may contain a reference to another section of the text that relates to the subject at hand. It may also highlight important technical information. For example:

Note!
For more information on on-board diagnostics, refer to Chapter 18, *Computer System Troubleshooting.*

A *caution* identifies a situation that may cause damage to a vehicle, equipment, or tools if the proper procedures are not followed. For example:

Caution!
Tighten an alternator belt only enough to prevent slippage. Overtightening is a common mistake that can quickly ruin alternator bearings.

Cautions that warn *against* certain procedures or activities are identified by a "do not" icon:

Caution!
Do not disconnect the EFI harness terminal when the ignition switch is in the *on* position. This can damage the control module.

A *warning* identifies repair operations that can result in personal injury if proper procedures or safety measures are not followed. For example:

Warning!
A steam cleaner operates at high pressures and temperatures. Follow the manufacturer's safety rules and operating instructions.

When a warning refers to a particular danger or warns reader to wear protective gear, specific icons are used to help clearly identify the hazard. For example:

Warning!
Always wear eye protection when cleaning parts with power tools. Metal bristles, bits of carbon, or metal pieces from a broken tool or part can fly into your face.

Other warning icons used in this text include:

Face shield required.

Respirator required.

Body protection required.

Shock or electrocution hazard.

Fire hazard.

Explosion hazard.

Injury hazard (rotating parts, hot surfaces, etc.).

Tech tips provide supplemental technical information and service hints related to the procedure or system being explained. For example:

Tech Tip!
Oxygen sensors should be replaced at periodic intervals. After prolonged service, they become coated with exhaust byproducts. As this happens, fuel economy and emissions will be adversely affected. If gas mileage is 10% to 15% lower than normal, suspect the oxygen sensor of slow response.

Repair Procedures

Procedures present common service and repair operations in an easy-to-follow, step-by-step format. For example:

To perform an injector balance test:

1. Connect a pressure gauge to the test fitting on the fuel rail.

2. Close off the valve for measuring fuel volume if provided on the fuel gauge assembly.
3. Connect the balance tester wiring to the injectors or injector in question.
4. Turn the ignition key on to pressurize the system. Then, turn the ignition key off.
5. Press the injector balance tester button while watching the pressure gauge drop.
6. Record the pressure drop reading.
7. Repeat this on the other fuel injectors. This will allow you to measure how much fuel each injector is feeding into the engine when energized.

Troubleshooting Charts

Troubleshooting charts have been added to the end of each service chapter. These charts will help the reader diagnose and repair common problems.

Duff's Garage

This feature is designed to help reinforce logical troubleshooting techniques. Each Duff's Garage presents a common automotive problem, details the procedure for pinpointing the source trouble, and provides an overview of the necessary repairs.

Accident Report, Customer Care, Highway History, Industry Trends and Workplace Skills Features

The new edition of the text contains a variety of features designed to generate interest in the field of automotive technology and cultivate the skills needed to succeed as an automotive technician. These features include:

Industry Trends—Highlights new and emerging technologies in the automotive industry.

Workplace Skills—Helps cultivate the skills needed to become a successful automotive technician.

Customer Care—Helps develop skills required to effectively interact with customers.

Highway History—Chronicles important milestones in the automobile industry.

Accident Reports—Emphasizes the importance of working safely.

Color Use

Color is used extensively throughout this text to enhance understanding and highlight important information. In illustrations, dark yellow is used for primary emphasis in illustrations and blue is used for secondary emphasis. Other colors are used as needed to help clarify the illustrations. For example, red arrows are often used to show motion. Color is also used to represent different pressures, states of matter, temperatures, etc.

Enhancing the Text

To aid in the learning process, a comprehensive workbook and a series of instructional videos have been created. These items are designed to be used with this text.

The workbook contains a variety of questions that correlate with the text and a number of jobs that are related to specific service or repair procedures.

The automotive videos also complement the material presented in this text and workbook. There are 49 videos, which can be purchased individually or as a package.

Both the workbook and videos can be purchased directly from Goodheart-Willcox Company, Inc.

Introduction to Automotive Technology

1. *The Automobile*
2. *Automotive Careers and ASE Certification*
3. *Basic Hand Tools*
4. *Power Tools and Equipment*
5. *The Auto Shop and Safety*
6. *Automotive Measurement and Math*
7. *Using Service Information*
8. *Basic Electricity and Electronics*
9. *Fasteners, Gaskets, Seals, and Sealants*
10. *Vehicle Maintenance, Fluid Service, and Recycling*

We are truly living in a "world of wheels." Every day, millions of people depend on their cars, trucks, vans, and sport-utility vehicles as their primary means of transportation. As a result, economic experts predict a strong demand for skilled automobile technicians and related professionals for the foreseeable future. You have chosen to study an area of employment that pays well and will require thousands of new graduates yearly.

Section 1 will introduce you to the "basics" of automotive technology. It contains information on automobile construction and operation, ASE certification, safety, tools, service information, electricity, and vehicle maintenance.

This section will give you the knowledge needed to secure an entry-level job. It will also lay the groundwork for later chapters, which provide in-depth coverage of automotive technology.

1

The Automobile

After studying this chapter, you will be able to:

- Identify and locate the most important parts of a vehicle.
- Describe the purpose of the fundamental automotive systems.
- Explain the interaction of automotive systems.
- Describe major automobile design variations.
- Comprehend later text chapters with a minimum amount of difficulty.
- Correctly answer ASE certification test questions that require a knowledge of the major parts and systems of a vehicle.

The term ***automobile*** is derived from the Greek word *autos,* which means self, and the French word *mobile,* which means moving. Today's "self-moving" vehicles are engineering marvels of safety and dependability. Over the last century, engineers and skilled workers the world over have used all facets of ***technology*** (the application of math, science, physics, and other subjects) to steadily give us a better means of transportation.

You are about to begin your study of the design, construction, service, maintenance, and repair of the modern automobile. This chapter provides a "quick look" at the major automotive systems. By knowing a little about each of these systems, you will be better prepared to learn the more detailed information presented later in this text.

Today, failure of one system can affect the operation of a seemingly unrelated system. This makes a thorough understanding of how the whole automobile works especially important.

Tech Tip!

Try to learn something new about automotive technology every day. In addition to studying this book and doing the hands-on activities, read automotive magazines, "surf" the Internet, and watch "motor-sport" television programs. This will help you become a better technician by increasing you knowledge daily.

Parts, Assemblies, and Systems

A ***part*** is the smallest removable item on a car. A part is not normally disassembled. The word ***component*** is frequently used when referring to an electrical or electronic part. For example, a spark plug is an ignition system component that ignites the fuel in the engine.

An ***assembly*** is a set of fitted parts designed to complete a function. For example, the engine is an assembly that converts fuel into useable power to move the vehicle. Technicians must sometimes take assemblies apart and put them back together during maintenance, service, and repair operations. See **Figure 1-1**.

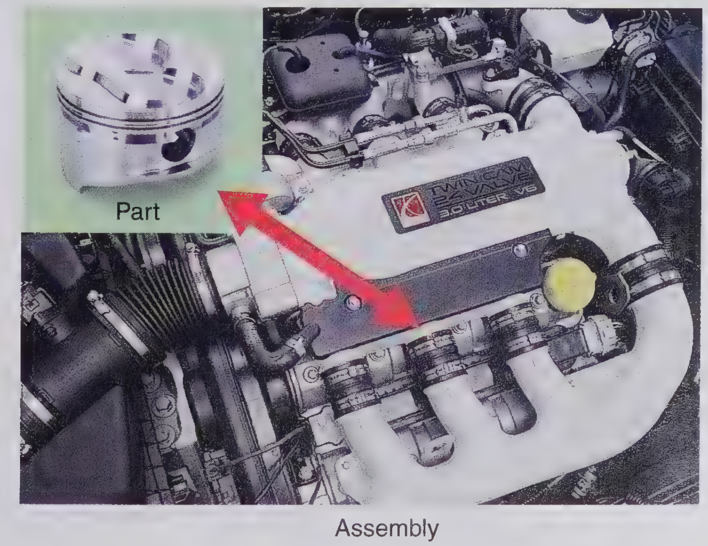

Figure 1-1. An assembly is a group of parts that work together to perform a function. For example, an engine is an assembly that contains pistons, which convert the fuel's heat energy into useable kinetic energy (motion). As you will learn, an engine has many other parts. (Saturn)

An automotive ***system*** is a group of related parts and assemblies that performs a specific function (job or task). For example, your vehicle's steering system contains the steering wheel, steering shaft, steering gears, linkage rods, and other parts. These parts allow you to control the direction of the wheels and tires for maneuvering (turning) your vehicle. Another example of a familiar system is the brake system. This system is a group of parts that performs a very important task—slowing and stopping your vehicle quickly and safely.

Figure 1-2 shows the major systems of a vehicle. Memorize the name and general location of each system. Automotive parts and systems can be organized into ten major categories:

- *Body and frame*—support and enclose the vehicle.
- *Engine*—provides dependable, efficient power for the vehicle.
- *Computer systems*—monitor and control various vehicle systems.
- *Fuel system*—provides a combustible air-fuel mixture to power the engine.
- *Electrical system*—generates and/or distributes the power needed to operate the vehicle's electrical and electronic components.
- *Cooling and lubrication systems*—prevent engine damage and wear by regulating engine operating temperature and reducing friction between internal engine parts.
- *Exhaust and emission control systems*—quiet engine noise and reduce toxic substances emitted by the vehicle.
- *Drive train systems*—transfer power from the engine to the drive wheels.
- *Suspension, steering, and brake systems*—support and control the vehicle.
- *Accessory and safety systems*—increase occupant comfort, safety, security, and convenience.

Frame, Body, and Chassis

The body and frame are the two largest sections of a motor vehicle. The ***frame*** is the strong metal structure that provides a mounting place for the other parts of the vehicle. The frame holds the engine, transmission, suspension, and other assemblies in position.

The ***body*** is a steel, aluminum, fiberglass, plastic, or composite skin forming the outside of the vehicle. The body is painted to give the vehicle an attractive appearance.

The term ***chassis*** is often used when referring to a vehicle's frame and everything mounted to it except the body—tires, wheels, engine, transmission, drive axle assembly, and frame. You can see the complex network of automotive parts and systems on the chassis shown in **Figure 1-3A**. When each part or system is "disassembled and studied" separately, you will find the inner workings of a motor vehicle easy to understand.

Figure 1-2. Note the general location of the major vehicle systems. Study the flow of fuel, air, exhaust, and power.

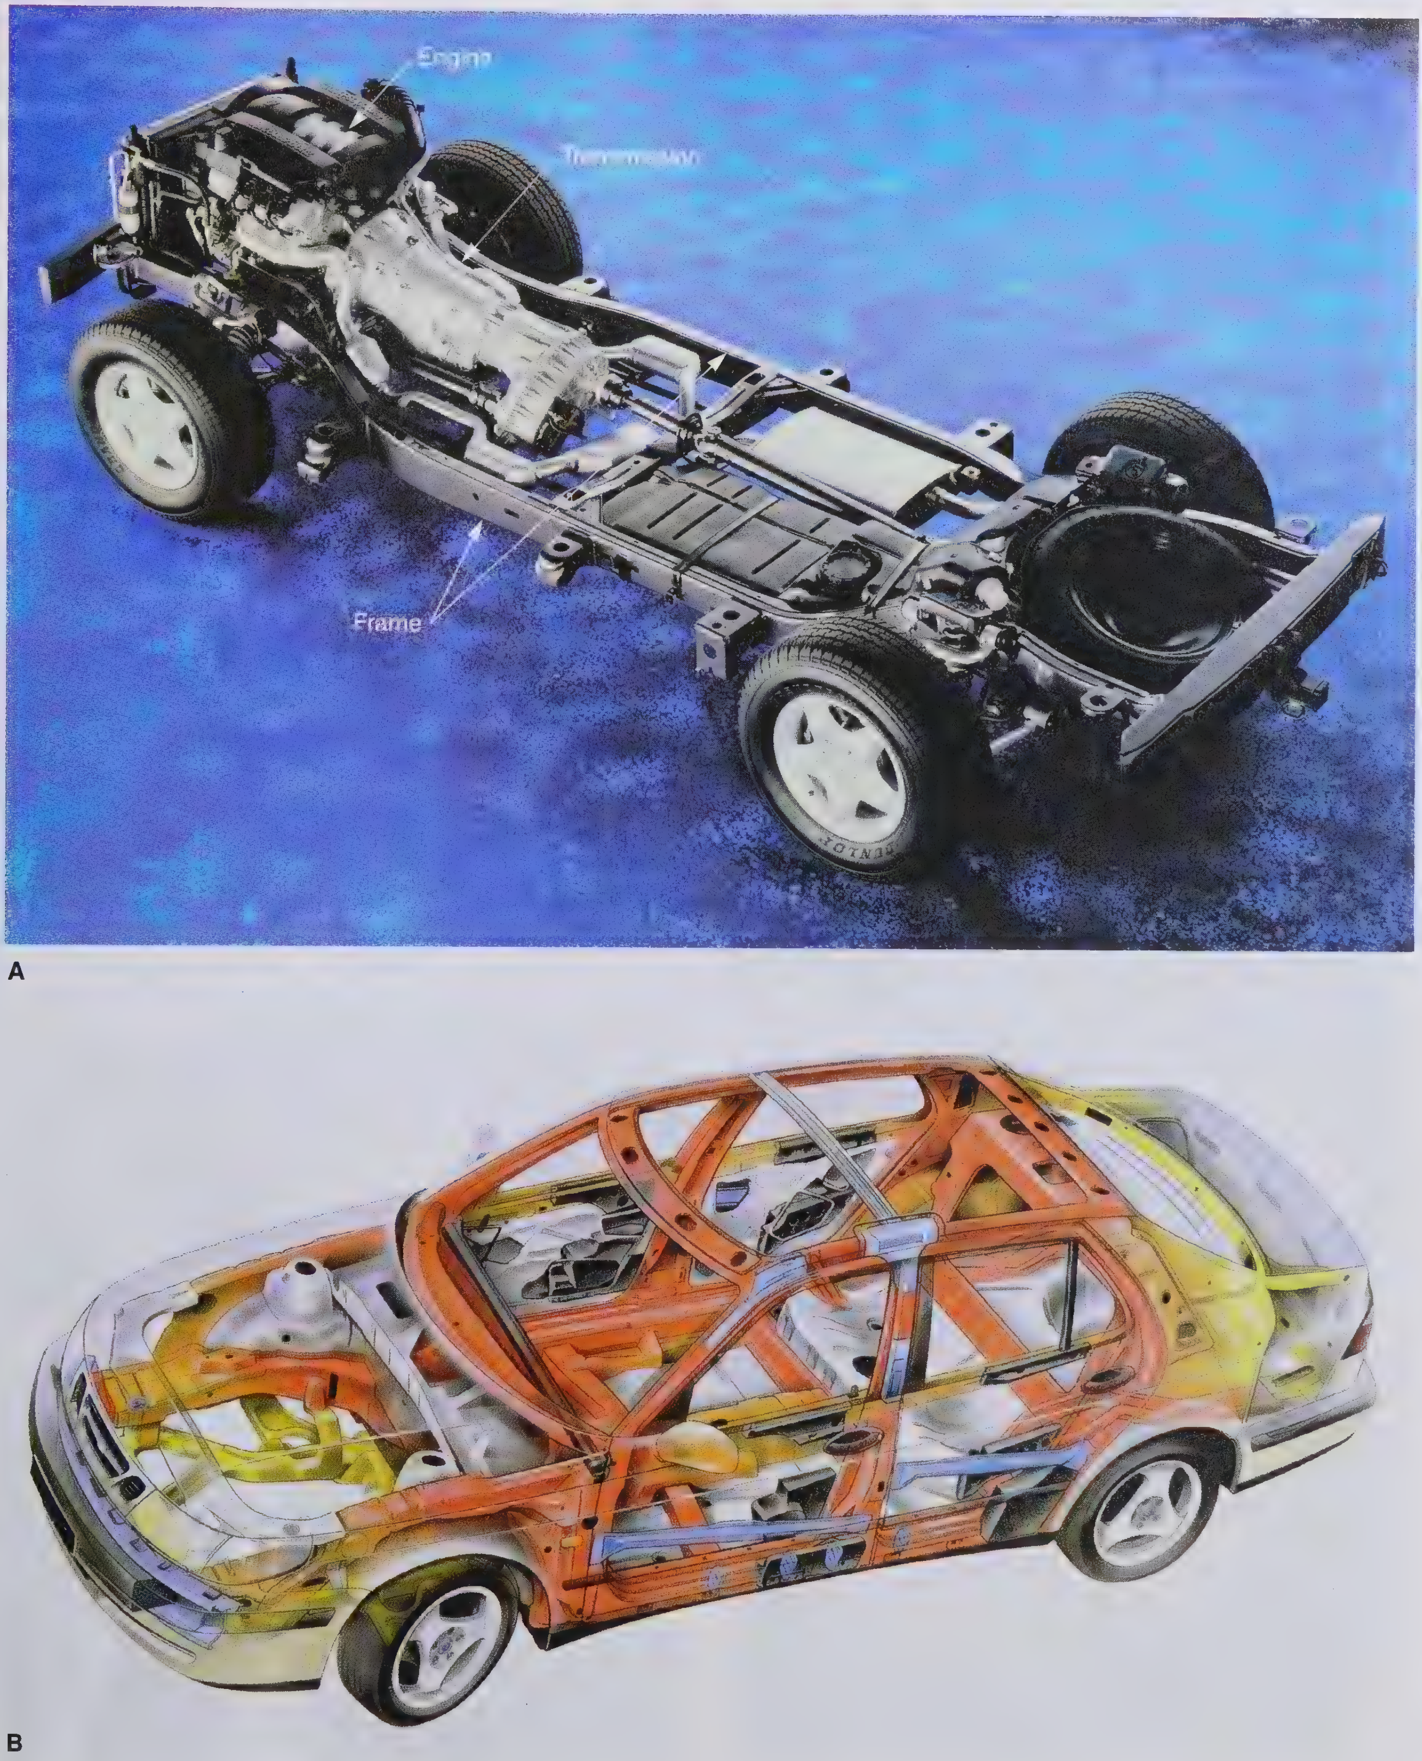

Figure 1-3. Compare body-over-frame and unibody construction. A—In body-over-frame construction, the chassis parts bolt to a strong perimeter frame. The body bolts to this thick steel frame. B—Unibody vehicles do not have a separate perimeter frame. Chassis components bolt directly to the unibody assembly. (DaimlerChrysler, Saab)

In ***body-over-frame construction***, the frame consists of thick steel members. The chassis parts and the body bolt to this frame. Also called full frame construction or perimeter frame construction, this design is heavy but strong. Body-over-frame construction is used on full-size cars, vans, pickup trucks, and sport-utility vehicles (SUVs). See **Figure 1-3A**.

With ***unibody construction***, sheet metal body panels are welded together to form the body and frame. Also called *space frame construction* or *unitized construction*, this is the most common type of configuration used to build small and medium passenger cars. Unibody construction reduces weight, improves fuel economy, and has a high strength-to-weight ratio. However, unibody vehicles are not as strong as those with body-over-frame construction. See **Figure 1-3B**.

Body Types

Automobiles are available in several body types, including the sedan, hardtop, convertible, hatchback, and station wagon. In addition, the minivan, the sport-utility vehicle, and the pickup truck have become increasingly popular.

A ***sedan*** is a car that has front and back seats and will carry four to six people. It has center body pillars, or "B" pillars, between the front and rear doors, **Figure 1-4A.** Both two-door and four-door sedans are available.

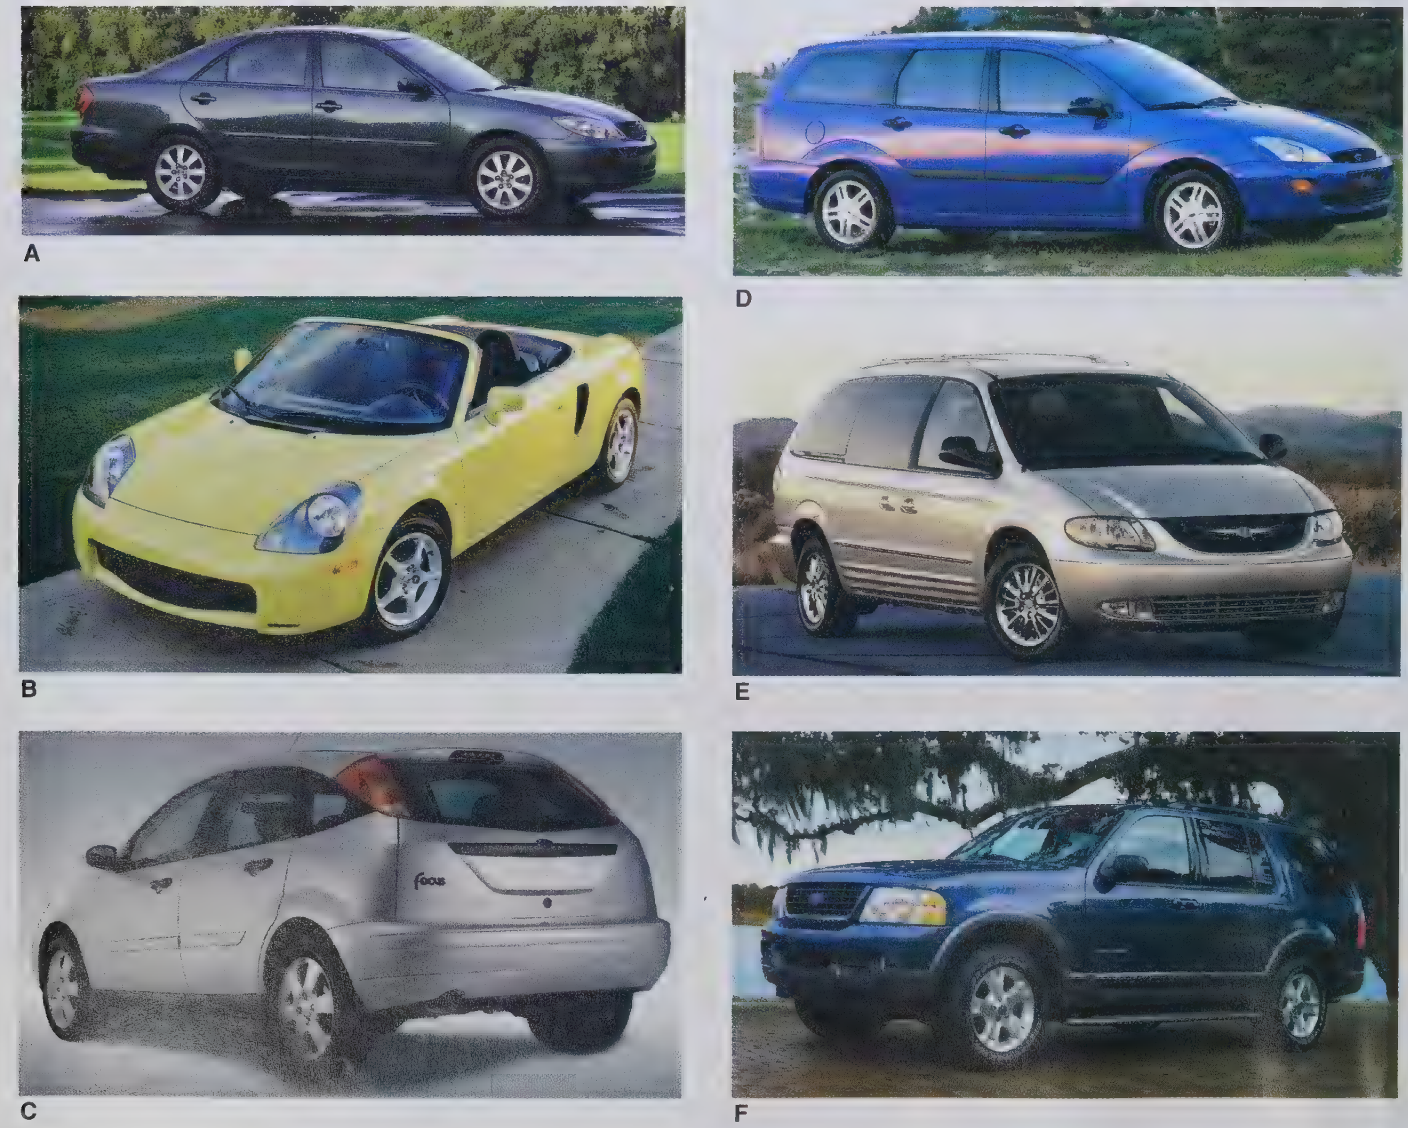

Figure 1-4. Note the various vehicle body styles. A—Sedan. B—Convertible. C—Hatchback. D—Station wagon. E—Minivan. F—Sport-utility vehicle. (DaimlerChrysler, Ford, Toyota)

A ***hardtop*** is similar to the sedan, but it has no "B" pillars. Hardtop vehicles are also available in both two- and four-door models.

A ***convertible*** has a vinyl or cloth top that can be raised and lowered. A convertible has no door pillars, and its strength is designed into the frame or floor pan. Although most convertibles are two-door models, **Figure 1-4B,** a few four-door convertibles have been produced.

A ***hatchback,*** or ***liftback,*** has a large rear door for easy access when hauling items. This style car is available in three- and five-door models, **Figure 1-4C.**

A ***station wagon*** has a long, straight roof that extends to the rear of the vehicle. Station wagons have large rear interior compartments and come in two- and four-door models. Some station wagons have space for up to nine passengers, see **Figure 1-4D.**

The ***minivan*** is similar to the station wagon, but it has a higher roofline for more headroom and cargo space. Most minivans are designed to carry seven passengers. See **Figure 1-4E.**

Sport-utility vehicles are often equipped with four-wheel-drive systems and have a tall body design. They provide the comfort of a passenger car, the interior space of a station wagon, and the durability of a truck, **Figure 1-4F.**

Common names for various automobile body parts are shown in **Figure 1-5.** Note that a vehicle's right and left sides are denoted as if you were sitting in the car looking forward.

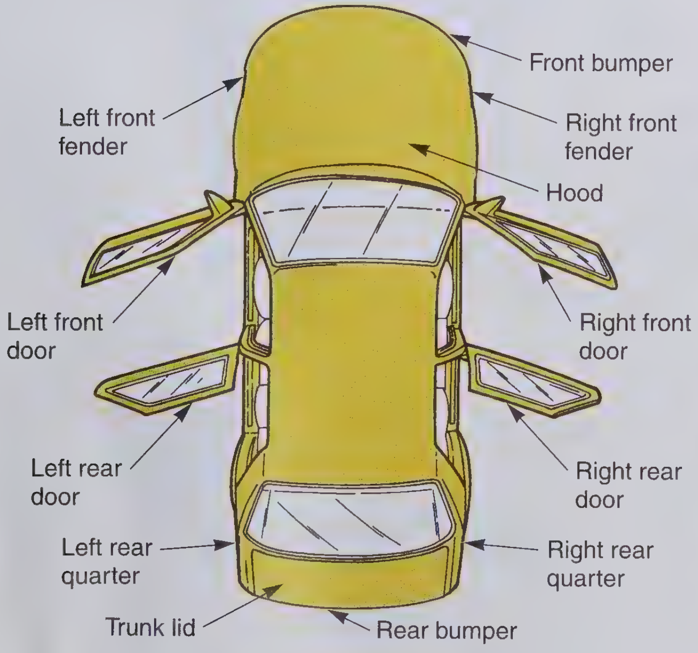

Figure 1-5. The right and left sides of a vehicle are denoted as if you were sitting forward inside passenger compartment.

Engine

The ***engine*** provides the energy to propel (move) the vehicle and operate the other systems. Most engines consume gasoline or diesel fuel. The fuel burns in the engine to produce heat. This heat causes gas expansion, creating pressure inside the engine. The pressure moves internal engine parts to produce power. See **Figure 1-6.**

The engine is usually located in the front portion of the body. Placing the heavy engine in this position makes the vehicle safer in the event of a head-on collision. In a few vehicles, the engine is mounted in the rear to improve handling. Refer to **Figure 1-7.**

Basic Engine Parts

The basic parts of a simplified one-cylinder engine are shown in **Figure 1-8.** Refer to this illustration as each part is introduced.

- The ***block*** is metal casting that holds all the other engine parts in place.
- The ***cylinder*** is a round hole bored (machined) in the block. It guides piston movement.
- The ***piston*** is a cylindrical component that transfers the energy of combustion (burning of air-fuel mixture) to the connecting rod.
- The ***rings*** seal the small gap around the sides of the piston. They keep combustion pressure and oil from leaking between the piston and the cylinder wall (cylinder surface).
- The ***connecting rod*** links the piston to the crankshaft.
- The ***crankshaft*** changes the *reciprocating* (up-and-down) motion of the piston and rod into useful *rotary* (spinning) motion.

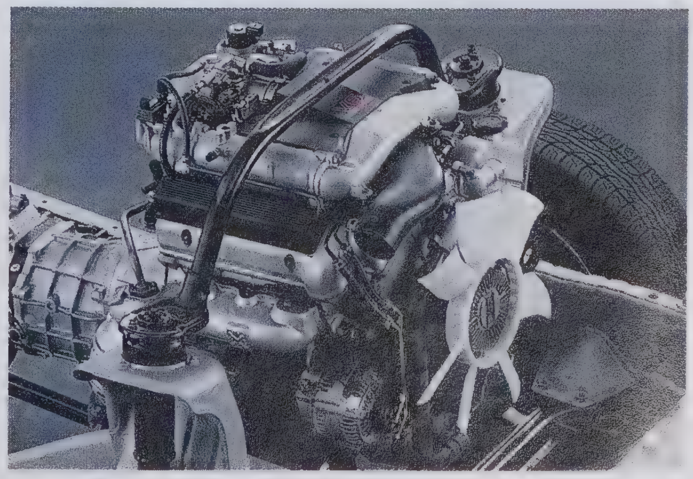

Figure 1-6. An automotive engine commonly burns gasoline or diesel fuel to produce power. (Suzuki)

- The ***cylinder head*** covers and seals the top of the cylinder. It also holds the valves, rocker arms, and often, the camshaft.
- The ***combustion chamber*** is a small cavity (hollow area) between the top of the piston and the bottom of the cylinder head. The burning of the air-fuel mixture occurs in the combustion chamber.
- The ***valves*** open and close to control the flow of the air-fuel mixture into the combustion chamber and the exhaust gases out of the combustion chamber.
- The ***camshaft*** controls the opening of the valves.
- The ***valve springs*** keep the valves closed when they do not need to be open.
- The ***rocker arms*** transfer camshaft action to the valves.
- The ***lifters,*** or ***followers,*** ride on the camshaft and transfer motion to the other parts of the valve train.
- The ***flywheel*** helps keep the crankshaft turning smoothly. It also provides a large gear for the starting motor.

Longitudinal engine mounting
Rear engine, rear-wheel drive

Figure 1-7. The engine can be located in the front or rear of the vehicle. (Dana Corp.)

Four-Stroke Cycle

Automobile engines normally use a ***four-stroke cycle.*** Four separate piston ***strokes*** (up or down movements) are needed to produce one ***cycle*** (complete series of events). The piston must slide down, up, down, and up again to complete one cycle.

As the four strokes are described below, study the simple drawings in **Figure 1-9.**

1. The ***intake stroke*** draws the air-fuel mixture into the engine's combustion chamber. The piston slides down while the intake valve is open and the exhaust valve is closed. This produces a vacuum (low-pressure area) in the cylinder. Atmospheric pressure (outside air pressure) can then force air and fuel into the combustion chamber.
2. The ***compression stroke*** prepares the air-fuel mixture for combustion. With both valves closed, the piston slides upward and compresses (squeezes) the trapped air-fuel mixture.

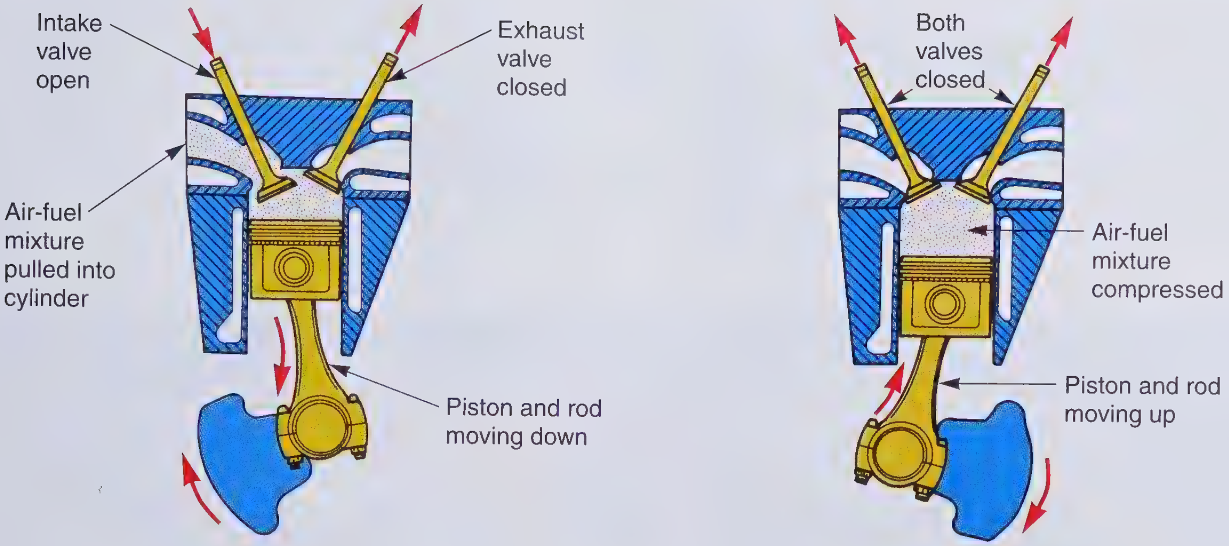
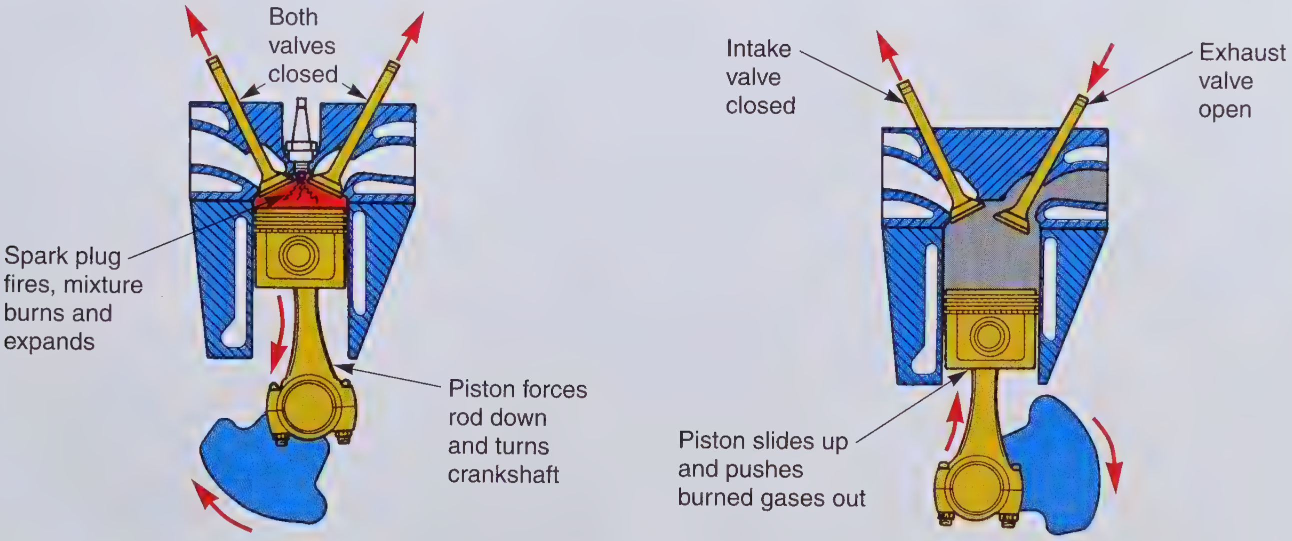
Figure 1-8. Memorize the basic parts of this one-cylinder engine.



Intake valve open
Exhaust valve closed
Air-fuel mixture pulled into cylinder
Piston and rod moving down
Both valves closed
Air-fuel mixture compressed
Piston and rod moving up

1—Intake stroke. Intake valve open. Exhaust valve closed. Piston slides down, forming vacuum in cylinder. Atmospheric pressure pushes air and fuel into combustion chamber.

2—Compression stroke. Both valves are closed. Piston slides up and pressurizes air-fuel mixture. This readies mixture for combustion.



Both valves closed
Spark plug fires, mixture burns and expands
Piston forces rod down and turns crankshaft
Intake valve closed
Exhaust valve open
Piston slides up and pushes burned gases out

3—Power stroke. Spark plug sparks. Air-fuel mixture burns. High pressure forces piston down with tremendous force. Crankshaft rotates under power.

4—Exhaust stroke. Exhaust valve opens. Intake valve remains closed. Piston slides up, pushing burned gases out of cylinder. This prepares combustion chamber for another intake stroke.

Figure 1-9. A gasoline engine normally operates on a four-stroke cycle. Study the series of events.

3. The ***power stroke*** produces the energy to operate the engine. With both valves still closed, the spark plug arcs (sparks) and ignites the compressed air-fuel mixture. The burning fuel expands and develops pressure in the combustion chamber and on the top of the piston. This pushes the piston down with enough force to keep the crankshaft spinning until the next power stroke.
4. The ***exhaust stroke*** removes the burned gases from the combustion chamber. During this stroke, the piston slides up while the exhaust valve is open and the intake valve is closed. The burned fuel mixture is pushed out of the engine and into the exhaust system.

During engine operation, these four strokes are repeated over and over. With the help of the heavy flywheel, this action produces smooth, rotating power output at the engine crankshaft.

Obviously, other devices are needed to lubricate the engine parts, operate the spark plug, cool the engine, and provide the correct fuel mixture. These devices will be discussed shortly.

Automotive Engines

Unlike the basic one-cylinder engine just discussed, automotive engines are ***multi-cylinder engines,*** which means they have more than one piston and cylinder. Vehicles commonly have 4-, 6-, 8-, or 10-cylinder engines. The additional cylinders smooth engine operation because there is less time (degrees of crankshaft rotation) between power strokes. Additional cylinders also increase power output.

An actual automotive engine is pictured in **Figure 1-10.** Study the shape, location, and relationship of the major parts.

Computer System

The ***computer system*** uses electronic and electrical devices to monitor and control various systems in the vehicle, including the fuel, ignition, drive train, safety, and security systems. See **Figure 1-11.** The use of computer systems has improved vehicle efficiency and dependability. Additionally, most of these systems have self-diagnostic capabilities. There are three major parts of an automotive computer system:

- ***Sensors***—input devices that can produce or modify electrical signals with a change in a condition, such as motion, temperature, pressure, etc. The sensors are the "eyes, ears, and nose" of the computer system.
- ***Control module***—computer (electronic circuit) that uses signals from input devices (sensors) to control various output devices. The control module is the "brain" of the computer system.
- ***Actuators***—output devices, such as small electric motors, that can move parts when energized by the control module. The actuators serve as the "hands and arms" of the computer system.

A modern car can have several control modules and dozens of sensors and actuators. These components will be detailed throughout this book.

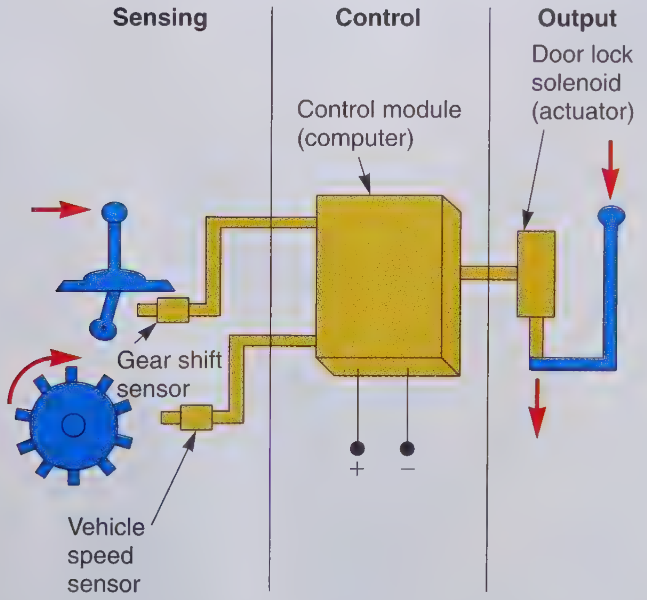

Figure 1-11. This computer-controlled lock system automatically locks the doors as soon as the vehicle starts moving. When the gear shift sensor and the vehicle speed sensor send the correct signals to the control module, the module energizes the solenoid (actuator). The solenoid then converts the electrical signal from the control module to a linear motion, locking the doors.

Tech Tip!
Learn all you can about electricity and electronics. Nearly every automotive system is now monitored or controlled by a computer. It is almost impossible to service any system of a car without handling some type of electric or electronic component. This book covers electronics in almost every chapter.

Fuel System

The ***fuel system*** must provide the correct mixture of air and fuel for efficient ***combustion*** (burning). This system must add the right amount of fuel to the air entering the cylinders. This ensures that a very ***volatile*** (burnable) mixture enters the combustion chambers.

The fuel system must also alter the ***air-fuel ratio*** (percentage of air and fuel) with changes in operating conditions (engine temperature, speed, load, and other variables).

There are three basic types of automotive fuel systems: gasoline injection systems, diesel injection systems, and carburetor systems. Look at the three illustrations in **Figure 1-12**.

Gasoline Injection System

Modern ***gasoline injection systems*** use a control module, sensors, and electrically operated ***fuel injectors*** (fuel valves) to meter fuel into the engine. This is the most common type of fuel system on gasoline, or spark ignition, engines. See **Figure 1-12A.**

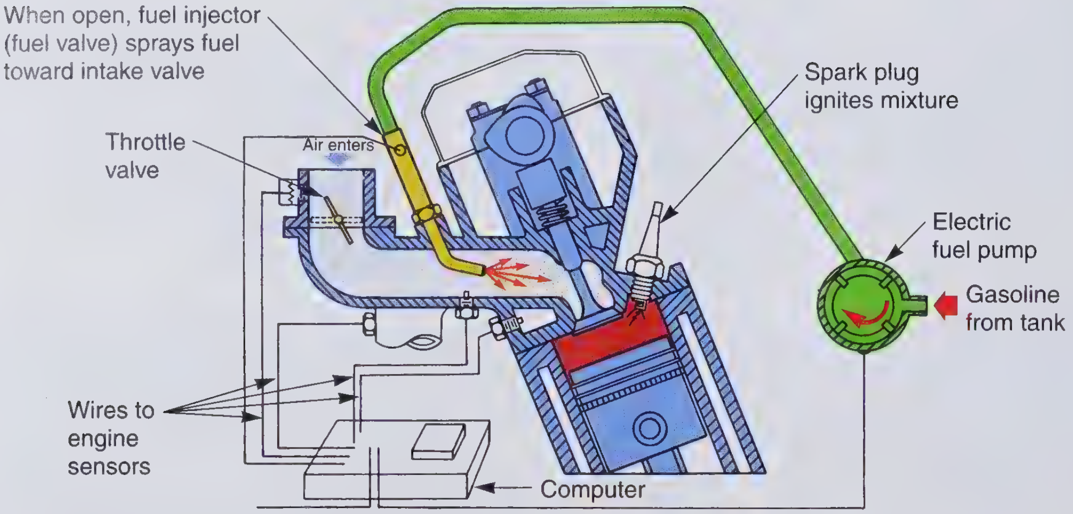
An electric ***fuel pump*** forces fuel from the fuel tank to the engine. The control module, reacting to electrical data it receives from the sensors, opens the injectors for the correct amount of time. Fuel sprays from the open injectors, mixing with the air entering the combustion chambers.

A ***throttle valve*** controls airflow, engine speed, and engine power. When the throttle valve is open for more engine power output, the computer holds the injectors open longer, allowing more fuel to spray out. When the throttle valve is closed, the computer opens the injectors for only a short period of time, reducing power output.

The throttle valve (air valve) is connected to the accelerator pedal. When the pedal is pressed, the throttle valve opens to increase engine power output.

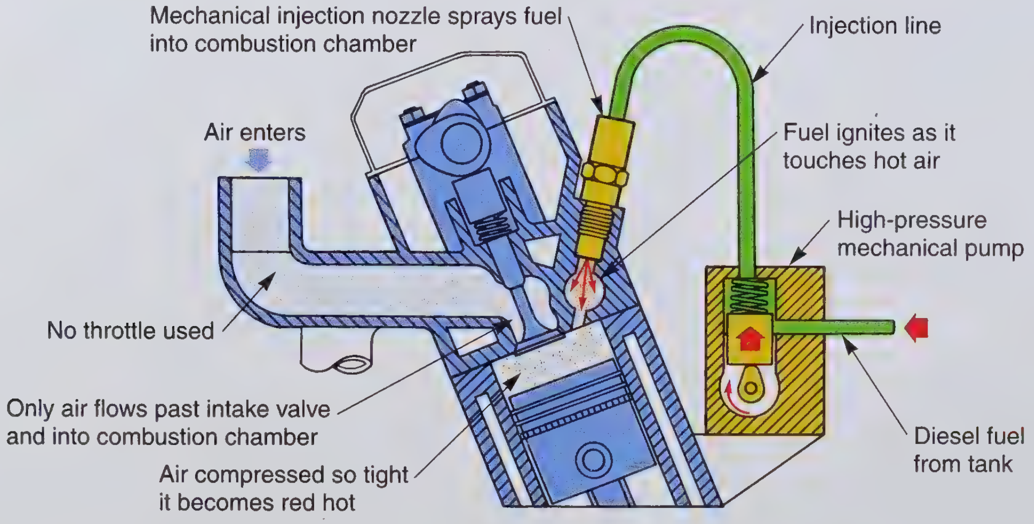
Diesel Injection System

A ***diesel fuel system*** is primarily a mechanical system that forces diesel fuel (not gasoline) directly into the combustion chambers. Unlike the gasoline engine, the diesel engine does *not* use spark plugs to ignite the air-fuel mixture. Instead, it uses the extremely high



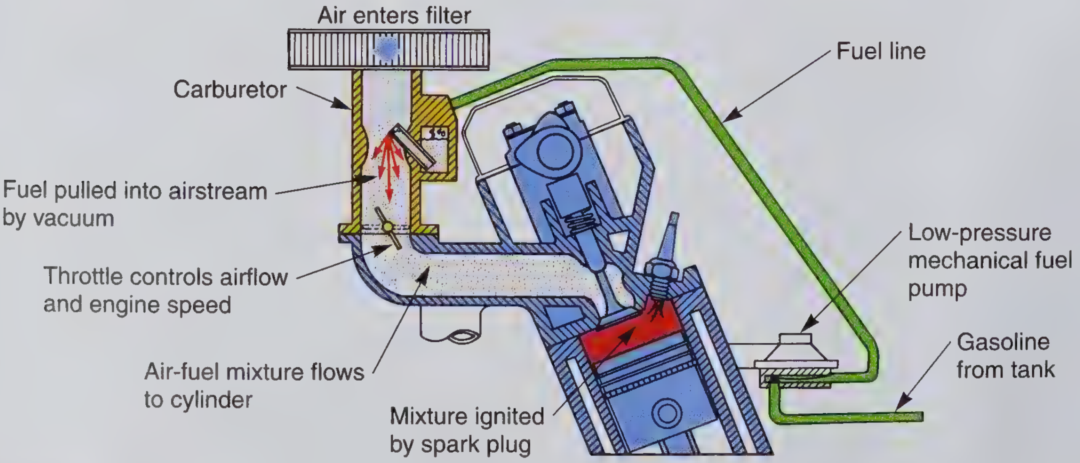
When open, fuel injector (fuel valve) sprays fuel toward intake valve
Throttle valve
Air enters
Spark plug ignites mixture
Electric fuel pump
Gasoline from tank
Wires to engine sensors
Computer

A—Gasoline injection system. Engine sensors feed information (electrical signals) to computer about engine conditions. Computer can then open injector for right amount of time. This maintains correct air-fuel ratio. Spark plug ignites fuel.



Mechanical injection nozzle sprays fuel into combustion chamber
Injection line
Air enters
Fuel ignites as it touches hot air
High-pressure mechanical pump
No throttle used
Only air flows past intake valve and into combustion chamber
Diesel fuel from tank
Air compressed so tight it becomes red hot

B—Diesel injection system. High-pressure mechanical pump sprays fuel directly into combustion chamber. Piston squeezes and heats air enough to ignite diesel fuel. Fuel begins to burn as soon as it touches heated air. Note that no throttle valve or spark plug is used. Amount of fuel injected into chamber controls diesel engine power and speed.



Air enters filter
Fuel line
Carburetor
Fuel pulled into airstream by vacuum
Low-pressure mechanical fuel pump
Throttle controls airflow and engine speed
Gasoline from tank
Air-fuel mixture flows to cylinder
Mixture ignited by spark plug

C—Carburetor fuel system. Fuel pump fills carburetor with fuel. When air flows through carburetor, fuel is pulled into engine in correct proportions. Throttle valve controls airflow and engine power output.

Figure 1-12. Note the three basic types of fuel systems. Compare differences.

pressure produced during the compression stroke to heat the air in the combustion chamber. The air is squeezed until it is hot enough to ignite the fuel. Refer to **Figure 1-12B.**

When the mechanical pump sprays the diesel fuel into a combustion chamber, the hot air in the chamber causes the fuel to begin to burn. The burning fuel expands and forces the piston down on the power stroke. Electronic devices are commonly used to monitor and help control the operation of today's diesel injection systems.

Carburetor Fuel System

The ***carburetor fuel system*** uses engine *vacuum* (suction) to draw fuel into the engine. The amount of airflow through the carburetor determines the amount of fuel used. This automatically maintains the correct air-fuel ratio. Refer to **Figure 1-12C.**

Either a mechanical or an electric fuel pump draws fuel out of the tank and delivers it to the carburetor. The engine's intake strokes form a vacuum inside the intake manifold and carburetor. This causes gasoline to be drawn from the carburetor and into the air entering the engine.

Electrical System

The vehicle's ***electrical system*** consists of several subsystems (smaller circuits): ignition system, starting system, charging system, and lighting system. Each subsystem is designed to perform a specific function, such as "fire" the spark plugs to ignite the engine's fuel mixture, rotate the crankshaft to start the engine, illuminate the highway for safe night driving, etc.

Ignition System

An ***ignition system*** is needed on gasoline engines to ignite the air-fuel mixture. It produces an extremely high voltage surge, which operates the ***spark plugs.*** A very hot electric arc jumps across the tip of each spark plug at the correct time. This causes the air-fuel mixture to burn, expand, and produce power. Study **Figure 1-13.**

With the ignition switch on and the engine running, the system uses sensors to monitor engine speed and other operating variables. Sensor signals are fed to the control module. The control module then modifies and ***amplifies*** (increases) these signals into on-off current pulses that

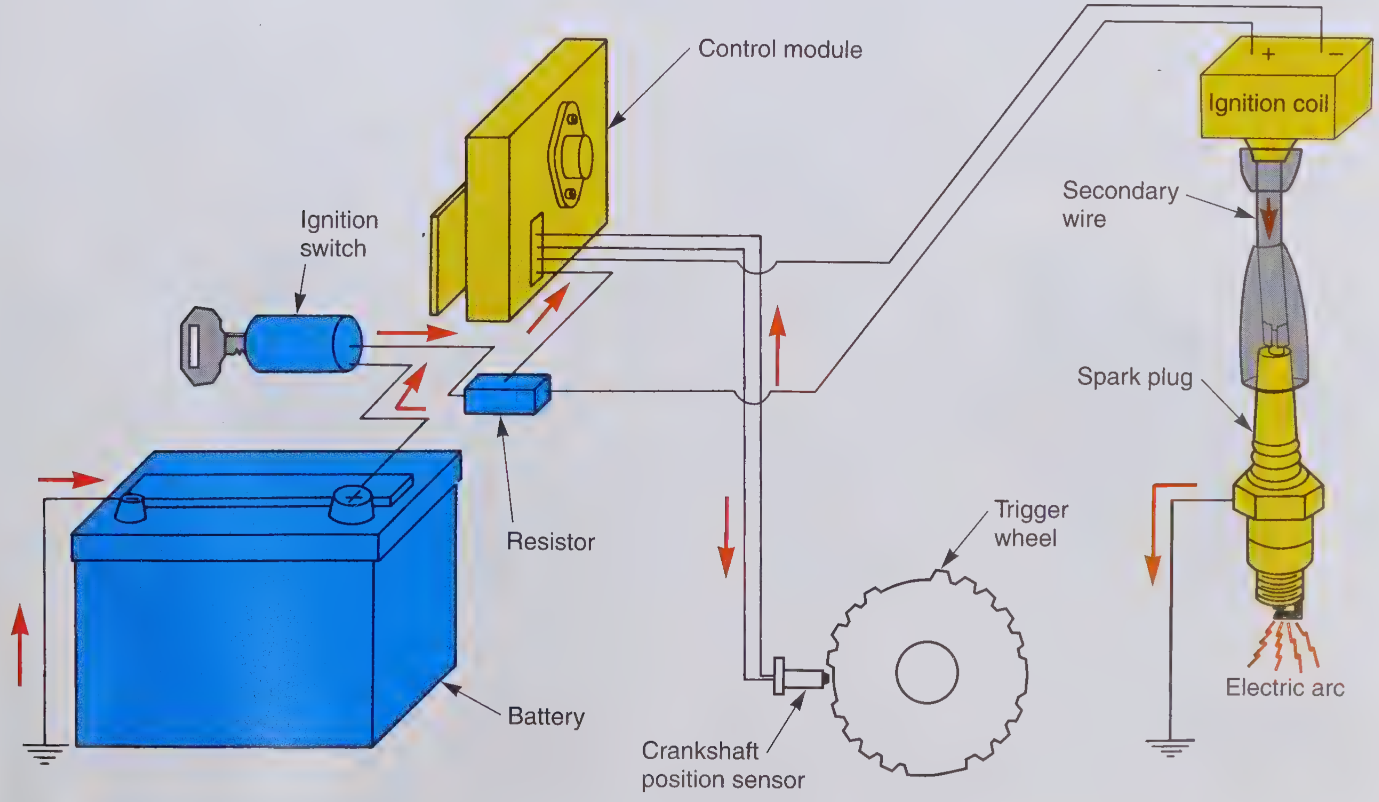


Figure 1-13. The ignition system is used on gasoline engines to start combustion. The spark plug must fire at the correct time during the compression stroke. A crankshaft position sensor or a distributor operates the ignition module. The module operates the ignition coil. The coil produces high voltage for the spark plugs.

trigger the ignition coil. When triggered, the ***ignition coil*** produces a high voltage output to "fire" the spark plugs. When the ignition key is turned off, the coil stops functioning and the spark-ignition engine stops running.

Starting System

The ***starting system*** has a powerful electric ***starting motor*** that rotates the engine crankshaft until the engine "fires" and runs on its own power. The major parts of the starting system are shown in **Figure 1-14A.**

A ***battery*** provides the electricity for the starting system. When the key is turned to the *start* position, current flows through the starting system circuit. The starting motor is energized, and the starting motor pinion gear engages a gear on the engine flywheel. This spins the crankshaft. As soon as the engine starts, the driver must shut off the starting system by releasing the ignition key.

Charging System

The ***charging system*** is needed to replace electrical energy drawn from the battery during starting system operation. To re-energize the battery, the charging system forces electric current back into the battery. The fundamental parts of the charging system are shown in **Figure 1-14B.** Study them!

When the engine is running, a ***drive belt*** spins the alternator pulley. The ***alternator*** (generator) can then produce electricity to recharge the battery and operate other electrical needs of the vehicle. A ***voltage regulator,*** usually built into the alternator, controls the voltage and current output of the alternator.

Lighting System

The ***lighting system*** consists of the components that operate a vehicle's interior and exterior lights (fuses, wires, switches, relays, etc.). The exact circuit and part configurations will vary from one model to another.

The *exterior lights* typically include the headlights, turn signals, brake lights, parking lights, backup lights, and side marker lights. The *interior lights* include the dome light, trunk light, instrument panel lights, and other courtesy lights.

Cooling and Lubrication Systems

The cooling and lubrication systems are designed to prevent engine damage and wear. They are important systems that prevent the engine from self-destructing.

The ***cooling system*** maintains a constant engine operating temperature. It removes excess combustion heat to prevent engine damage and also speeds engine warm-up. Look at **Figure 1-15.**

The ***water pump*** forces ***coolant*** (water and antifreeze solution) through the inside of the engine, hoses, and

radiator. The coolant collects heat from the hot engine parts and carries it back to the radiator.

The ***radiator*** allows the coolant heat to transfer into the outside air. An ***engine fan*** draws cool air through the radiator. The ***thermostat*** controls coolant flow and engine temperature. It is usually located where the top radiator hose connects to the engine.

The ***lubrication system*** reduces friction and wear between internal engine parts by circulating filtered engine oil to high-friction points in the engine. The lubrication system also helps cool the engine by carrying heat away from internal engine parts.

Study the parts and operation of the lubrication system shown in **Figure 1-16.** Note how the ***oil pump*** pulls oil out of the pan and pushes it to various moving parts of the engine.

Exhaust and Emission Control Systems

The ***exhaust system*** quiets the noise produced during engine operation and routes engine exhaust gases to the rear of the vehicle body. **Figure 1-17** illustrates the basic parts of an exhaust system. Trace the flow of exhaust gases from the engine exhaust manifold to the tailpipe. Learn the names of the parts.

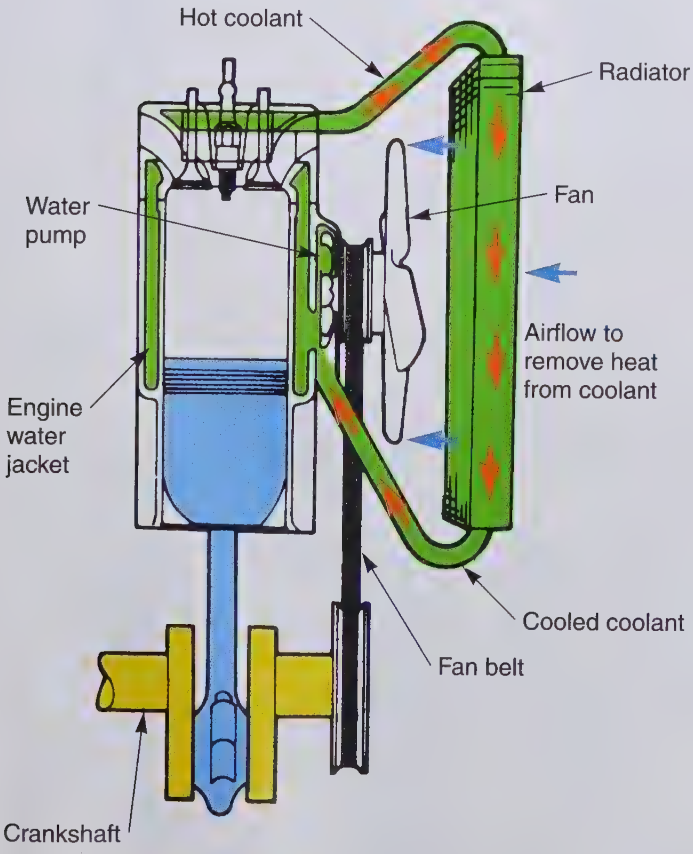

Figure 1-15. The cooling system must protect the engine from the heat of combustion. Combustion heat could melt and ruin engine parts. The system must also speed warm-up and maintain a constant operating temperature. Study the part names.

Various ***emission control systems*** are used to reduce the amount of *toxic* (poisonous) substances produced by an engine. Some systems prevent fuel vapors from entering the *atmosphere* (air surrounding the earth). Other emission control systems remove unburned and partially burned fuel from the engine exhaust. Later chapters cover these systems in detail.

Drive Train Systems

The ***drive train*** transfers turning force from the engine crankshaft to the drive wheels. Drive train configurations vary, depending on vehicle design. See **Figure 1-18.**

The drive train parts commonly found on a front-engine, rear-wheel-drive vehicle include the clutch, transmission, drive shaft, and rear axle assembly. The drive train parts used on most front-engine, front-wheel-drive vehicles include the clutch, transaxle, and drive axles. Refer to **Figure 1-18** as these components and assemblies are discussed.

Clutch

The ***clutch*** allows the driver to engage or disengage the engine and manual transmission or transaxle. When the clutch pedal is in the released position, the clutch locks the engine flywheel and the transmission input shaft together. This causes engine power to rotate the transmission gears and other parts of the drive train to propel the vehicle. When the driver presses the clutch pedal, the clutch disengages power flow and the engine no longer turns the transmission input shaft and gears.

Transmission

The ***transmission*** uses various gear combinations, or ratios, to multiply engine speed and torque to accommodate driving conditions. Low gear ratios allow the vehicle to accelerate quickly. High gear ratios permit lower engine speed, providing good gas mileage.

A ***manual transmission*** lets the driver change gear ratios to better accommodate driving conditions, **Figure 1-19.** An ***automatic transmission,*** on the other hand, does not have to be shifted by the driver. It uses an internal hydraulic system and, in most cases, electronic controls to shift gears. The input shaft of an automatic transmission is connected to the engine crankshaft through a ***torque converter*** (fluid coupling) instead of a clutch. The elementary parts of an automatic transmission are pictured in **Figure 1-20.**

Drive Shaft

The ***drive shaft,*** or propeller shaft, transfers power from the transmission to the rear axle assembly. Look at

Figure 1-21. It is a hollow metal tube with two or more universal (swivel) joints. The universal joints allow the rear suspension to move up and down without damaging the drive shaft.

Rear Axle Assembly

The ***rear axle assembly*** contains a differential and two axles. The ***differential*** is a set of gears and shafts that transmits power from the drive shaft to the axles. The ***axles*** are steel shafts that connect the differential and drive wheels, **Figure 1-21.**

Transaxle

The ***transaxle*** consists of a transmission and a differential in a single housing. Although a few rear-wheel-drive vehicles are equipped with transaxles, they are most commonly used with front-wheel-drive vehicles, **Figure 1-22.** Both manual and automatic transaxles are available. The internal parts of a modern transaxle assembly are illustrated in **Figure 1-23**.

Front Drive Axles

The ***front drive axles*** connect the transaxle differential to the hubs and wheels of the vehicle. These axles are equipped with constant-velocity joints, which allow the front wheels to be turned to the left or right and to move up and down.

Suspension, Steering, and Brake Systems

The suspension, steering, and brake systems are the movable parts of the chassis. They bolt or anchor to the frame and provide important functions that will be explained in the following sections.

Suspension System

The ***suspension system*** allows the vehicle's wheels and tires to move up and down with little effect on body movement. This makes the vehicle's ride smooth and safe. The suspension system also prevents excessive body lean when turning corners quickly.

Transverse (sideways) mounted engine
Front drive axles
Transaxle

Figure 1-22. Front-wheel-drive vehicles do not have a drive shaft or a rear drive axle assembly. The complete drive train is in the front of the vehicle. (Ford)

Steering System

The ***steering system*** allows the driver to control vehicle direction by turning the wheels right or left. It uses a series of gears, swivel joints, and rods to do this. Study the names of the parts in **Figure 1-24.**

Brake System

The ***brake system*** produces friction to slow or stop the vehicle. When the driver presses the brake pedal, fluid pressure actuates a brake mechanism at each wheel. These mechanisms force friction material (brake pads or shoes) against metal discs or drums to slow wheel rotation. **Figure 1-25** shows the fundamental parts of a brake system.

Accessory and Safety Systems

Common ***accessory systems*** include the air conditioner, sound system, power seats, power windows, and rear window defogger. Common ***safety systems*** include seat belts, air bags, and security systems. See **Figure 1-26.**

Highway History

Early automobile manufacturers originated in various ways. In many instances, they evolved from bicycle makers, carriage and wagon makers, and other types of industry. Early motorcars were similar to horse-drawn buggies, but they were equipped with noisy gasoline-powered engines, steam engines, or electric motors and batteries. A single lever called a tiller was used to steer the vehicle and another lever was used to apply the brakes.

Summary

- The body and frame support, stop, and enclose the vehicle.
- The engine provides dependable, efficient power for the vehicle.
- The intake stroke draws the air-fuel mixture into the engine combustion chamber.
- The compression stroke prepares the fuel mixture for combustion.
- The power stroke produces the energy to operate the engine.
- The exhaust stroke must remove the burned gases from the engine cylinders.
- The computer system uses electronic and electrical devices to monitor and control various systems in the vehicle.
- The fuel system provides the correct mixture of air and fuel for efficient combustion.
- Electrical systems operate the electrical-electronic devices.
- The cooling system maintains a constant engine operating temperature.
- The lubrication system reduces friction between internal engine parts.
- Emission control systems reduce air pollution produced by the vehicle.
- Drive train systems transfer turning force from the engine crankshaft to the drive wheels.
- Suspension, steering, and brake systems support and control the vehicle.
- Accessory and safety systems increase passenger comfort, safety, security and convenience.

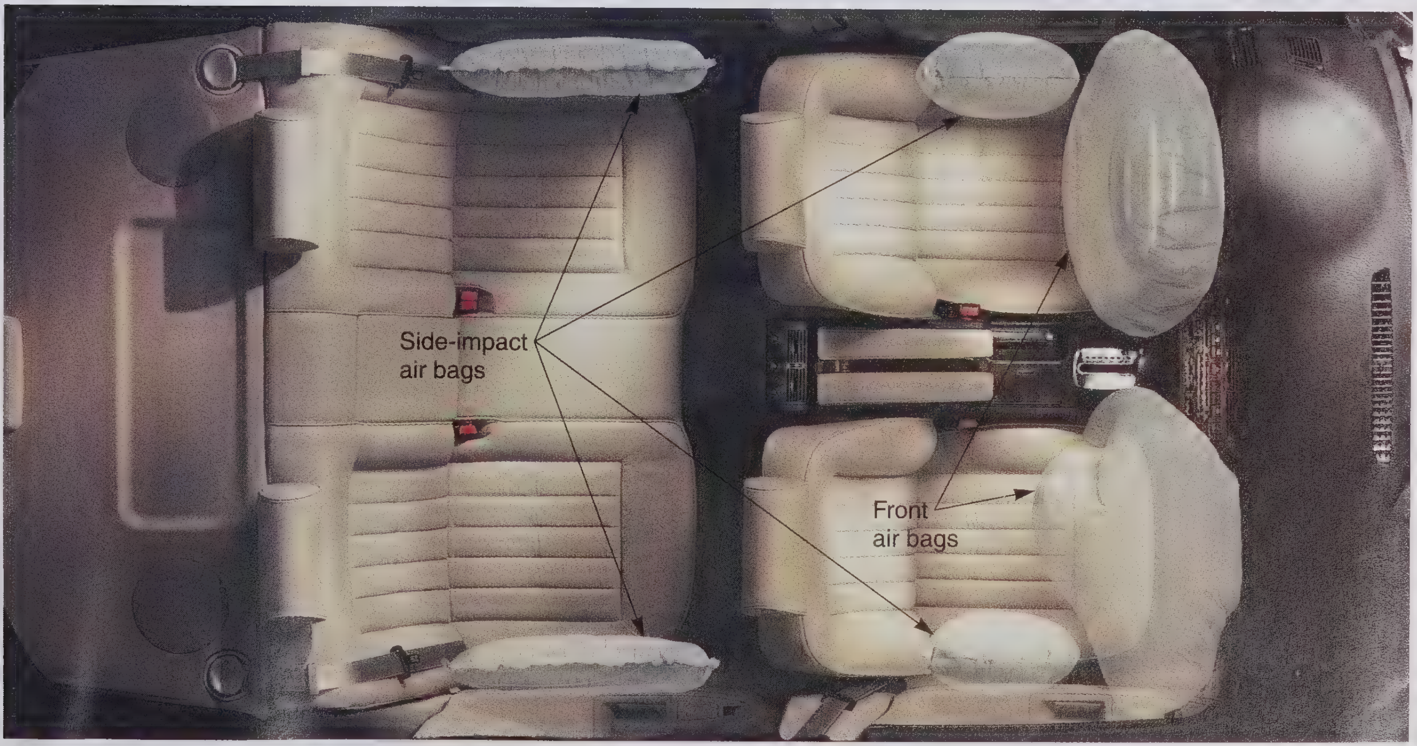

Figure 1-26. Various safety systems are used on modern vehicles to protect both the driver and the passengers. This vehicle is equipped with both front and side-impact air bags. (Audi)

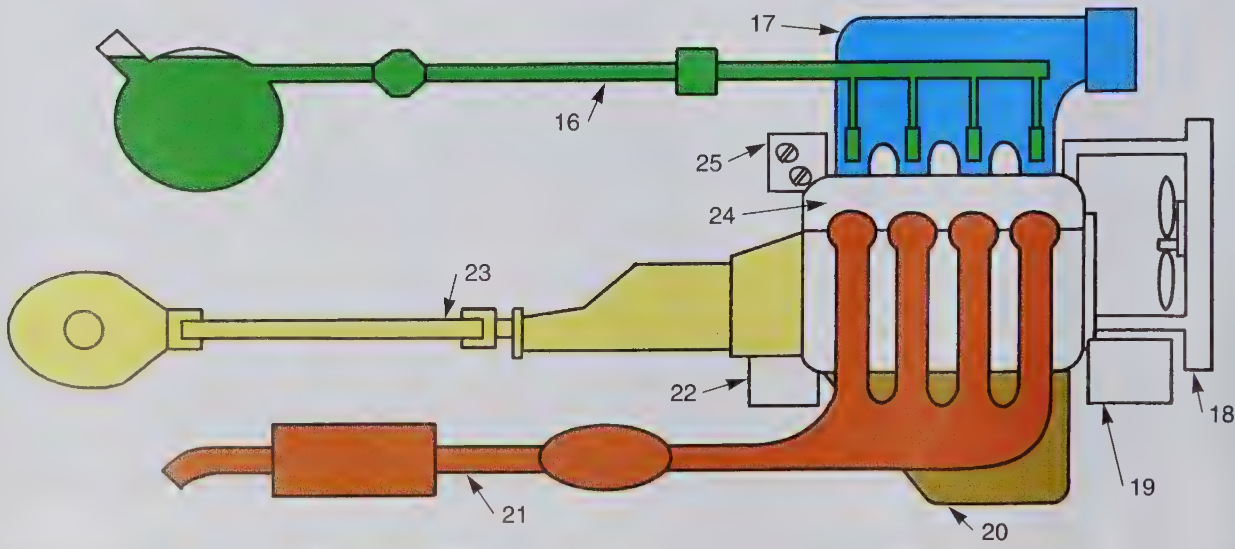
Review Questions—Chapter 1

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What is an automotive system?
2. Automotive parts and systems can be grouped into ten categories. Name them.
3. Which of the following is *not* part of an engine?
   (A) Block.
   (B) Piston.
   (C) Muffler.
   (D) Crankshaft.
4. Explain the engine's four-stroke cycle.
5. Most car engines are multi-cylinder engines. True or False?
6. List and describe the three common types of fuel systems.
7. A diesel engine does *not* use spark plugs. True or False?
8. The car's electrical system consists of the:
   (A) ignition, starting, lubrication, and lighting systems.
   (B) ignition, charging, lighting, and hydraulic systems.
   (C) lighting, charging, starting, and ignition systems.
   (D) None of the above.
9. The _____ _____ system reduces the amount of toxic substances released by the vehicle.
10. What is the difference between a manual transmission and an automatic transmission?
11. A one-piece drive shaft rotates the drive wheels on most front-wheel drive cars. True or False?
12. A rear axle assembly contains two _____ and a(n) _____.
13. Explain the term "transaxle."
14. The suspension system mounts the car's wheels solidly on the frame. True or False?
15. List four accessory systems.

16–25. Identify the parts and systems illustrated below. Write the numbers 16–25 on your paper. Then write the correct letter and words next to each number.



Can you identify the following parts and systems? (A) Starting system. (B) Charging system. (C) Drive train. (D) Fuel system. (E) Cooling system. (F) Engine. (G) Ignition system. (H) Lubrication system. (I) Exhaust system. (J) Intake manifold.

ASE-Type Questions

1. A vehicle is brought into the shop with a slipping clutch. Technician A says that the clutch is part of the drive train system. Technician B says that the clutch is part of the suspension system. Who is correct?
   (A) *A only.*
   (B) *B only.*
   (C) *Both A and B.*
   (D) *Neither A nor B.*
2. When the internal body structure of a vehicle is used as its frame, it is called:
   (A) *unibody construction.*
   (B) *body-frame construction.*
   (C) *integral construction.*
   (D) *body-over-frame construction.*
3. The _____ controls the opening of engine's valves.
   (A) *camshaft*
   (B) *crankshaft*
   (C) *valve springs*
   (D) *combustion chamber*
4. Which piston stroke of the four-stroke cycle prepares the fuel mixture for combustion?
   (A) *Power.*
   (B) *Intake.*
   (C) *Exhaust.*
   (D) *Compression.*
5. All of the following are major components in the computer system except:
   (A) *regulators.*
   (B) *sensors.*
   (C) *actuators.*
   (D) *computer.*
6. Each of the following is a basic type of automotive fuel system except:
   (A) *carburetor.*
   (B) *auto injection.*
   (C) *diesel injection.*
   (D) *gasoline injection.*
7. Tests show that an engine is not getting spark at the spark plugs. Technician A says it could be due to the diesel injection system. Technician B says to test the ignition coil. Who is right?
   (A) *A only.*
   (B) *B only.*
   (C) *Both A and B.*
   (D) *Neither A nor B.*
8. A car with a dead battery is brought into the shop. Technician A says to check the output of the alternator. Technician B says to check the condition of the spark plugs. Who is right?
   (A) *A only.*
   (B) *B only.*
   (C) *Both A and B.*
   (D) *Neither A nor B.*
9. Since an automatic transmission does not have to be shifted by hand, Technician A believes it uses a hydraulic system to shift gears. Technician B believes it uses oil pressure to shift gears. Who is right?
   (A) *A only.*
   (B) *B only.*
   (C) *Both A and B.*
   (D) *Neither A nor B.*
10. A transaxle case contains both the:
    (A) *carburetor and drive shaft.*
    (B) *transmission and differential.*
    (C) *multi-cylinder engine and clutch.*
    (D) *suspension components and brakes.*

Activities—Chapter 1

1. Draw an automotive engine and drive train and label the parts. Then describe how the power is transferred from the engine to the drive wheels.
2. Using illustrations from the text, produce overhead transparencies of the four-stroke cycle and demonstrate the cycle to your class.
3. Arrange a field trip to tour an automobile assembly plant or to an auto shop.

2

Automotive Careers and ASE Certification

After studying this chapter, you will be able to:

- List the most common automotive careers.
- Describe the type of skills needed to be an auto technician.
- Explain the tasks completed by each type of auto technician.
- Summarize the ASE certification program.

Over the last 25 years, the number of vehicles in the United States has increased by 40%. Today, there are well over one-hundred million vehicles on the road. In a single year, Americans spend approximately four-hundred billion dollars to own and operate their vehicles. Amazingly, there are about fourteen million people employed in the automotive field.

Economists predict a continued demand for skilled automotive technicians and other automotive-related professions for many years. Our country is, and will continue to be, a "nation on wheels."

The Automotive Technician

An ***automotive technician*** makes a living diagnosing, servicing, and repairing cars, vans, and light trucks. The technician must be highly skilled and well trained. He or she must be a "jack of all trades," being able to perform a wide variety of tasks. For example, an experienced master automobile technician is usually capable of performing operations common to the following occupations:

- *Machinist* (precision measurements, brake part machining).
- *Plumber* (working with fuel lines and power steering lines).
- *Welder* (gas and arc welding on exhaust systems, parts repair).
- *Electrician* (charging, starting, lighting system service).
- *Electronic technician* (servicing a vehicle's electronic parts).
- *Air conditioning technician* (repairing and recharging auto air conditioning).
- *TV-radio technician* (installing and repairing vehicle sound systems, cellular phones, and radios).
- *Computer technician* (servicing a vehicle's onboard computers).
- *Bookkeeper* (business-type tasks, such as filling out repair orders, calculating hours on a job, ordering parts, totaling work order costs, etc.).

As this list demonstrates, an automobile technician's job can be very challenging. The technician is called on to perform a variety of repair tasks, which prevents boredom on the job. If you like to use your mind and your hands, automotive service can be a rewarding and interesting profession.

General Job Classifications

A wide variety of jobs are available in the automotive field. Many of these jobs involve troubleshooting, service, and repair.

Service Station Attendant

A job as a ***service station attendant*** requires little mechanical experience, yet provides an excellent learning experience. A "gas station" with a repair area provides better training than a station without a repair area. You could learn to make simple repairs and work your way into a position as a "light mechanic." As a service station attendant, you might do oil changes, grease jobs, and similar service tasks.

Apprentice

Another way to get started in automotive service is to become an apprentice. The ***apprentice,*** or helper mechanic, works under the direction of an experienced technician.

This is a good way to get paid for an education. As an apprentice, you would learn about automotive technology by running for parts, cleaning parts, maintaining tools, and helping with repairs. See **Figure 2-1.**

Figure 2-1. An apprentice works under the direction of an experienced auto technician. This is an excellent way to learn the trade. (Fluke)

Specialized Technician

A ***specialized technician*** is an expert in one area of automotive repair, such as engines, brakes, electrical, or other areas. Because of the increasingly complex nature of today's vehicles, the trend is toward specialization. It is much easier to learn to repair one system than all systems. After specializing in one area, you can expand your abilities to include other areas of repair.

Common areas of specialization include engines, transmissions, steering and suspension, brakes, electrical, heating and cooling, driveability and performance, and lubrication.

An ***engine technician*** troubleshoots, services, and repairs automobile engines. Refer to **Figure 2-2.** This requires a knowledge of all types of engines: gasoline, diesel, 4-cylinder, 6-cylinder, 10-cylinder, etc. The engine technician has one of the most physically demanding automotive jobs. It requires a fairly strong individual who can lift heavy parts and easily torque large fasteners.

Figure 2-2. The engine technician must be highly skilled. Late-model engines are very complex. One mistake during assembly can cause major engine damage. (General Motors)

A ***transmission technician*** works on automatic and manual transmissions, transaxles, clutches, and, sometimes, rear axle assemblies. Because transmissions are so complex, the transmission technician must receive very specialized training and must frequently retrain. Some large service facilities have a rear axle specialist, who works on nothing but differentials, axle shafts, and drive shafts.

A ***steering and suspension technician*** is responsible for checking, replacing, and adjusting steering and suspension components. This technician must use specialized equipment, such as the wheel alignment rack, to line up the wheels. A steering and suspension technician may also take care of tire and wheel problems.

A ***brake technician*** specializes in brake system service and repair, **Figure 2-3.** This individual must be capable of rapidly diagnosing problems and making adjustments or repairs. A brake technician's job is one of the easiest to master. Jobs are available in both small and large shops, service stations, and tire outlets.

The ***electrical system technician*** must be able to test and repair lighting systems, charging systems, computer control systems, starting systems, and other electrical systems. Compared to other specialties, this area of repair might be desirable because it requires less physical strength than other areas. See **Figure 2-4.**

A ***heating and air conditioning technician*** must troubleshoot, service, and repair heaters, vents, and air conditioning systems. In some instances, this technician will install new air conditioning systems in vehicles. This requires considerable skill.

Figure 2-3. This brake technician is machining a brake drum. Brake repairs must be done correctly, since the safety of the customer and passengers is dependent on the operation of the brake system.

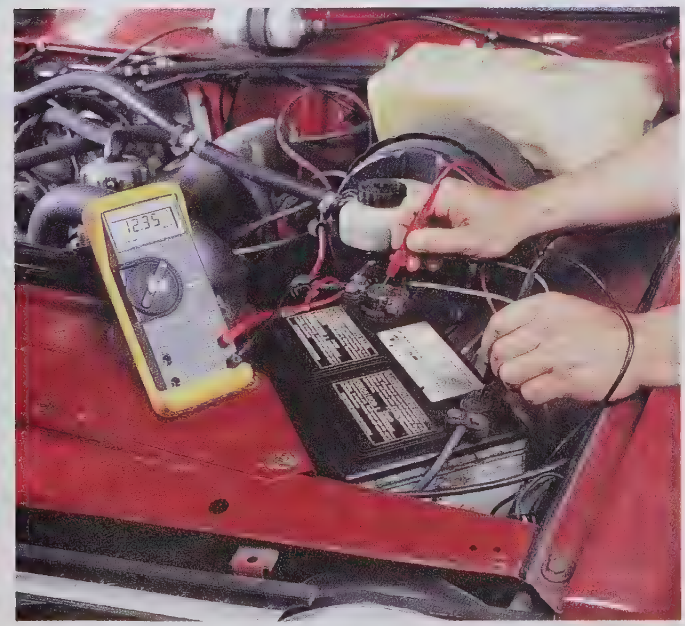


Figure 2-4. This electrical system technician is using a digital voltmeter to measure battery voltage. (Fluke)

The ***driveability and performance technician*** must test and service engine fuel, ignition, computer, and emission systems. As pictured in **Figure 2-5,** this involves the use of special test equipment to keep engines in top running condition. The driveability and performance expert must change spark plugs, as well as adjust and repair carburetors, fuel injection systems, and ignition system components.

Figure 2-5. The driveability and performance technician must use state-of-the-art equipment, such as this diagnostic analyzer, to find the source of engine performance problems. (ASE)

The ***lubrication specialist*** changes engine oil, filters, and transmission fluid. He or she checks various fluid levels and performs "grease jobs" (lubricates pivot points on suspension and steering systems).

Master Technician

A ***master technician,*** or ***general technician,*** is an experienced professional who has mastered *all* the specialized areas of automotive technology and is capable of working on almost any part of a vehicle. This person can service and repair engines, brakes, transmissions, axles, heaters, air conditioners, and electrical systems. A master technician generally has enough experience to advance to a position as a shop supervisor, a service manager, or an instructor.

Shop Supervisor

The ***shop supervisor*** is in charge of all the other technicians in the service facility. The supervisor must be able to help others troubleshoot problems in all automotive areas. The shop supervisor must also communicate with the service manager, parts manager, and technicians.

Service Manager

The ***service manager*** is responsible for the complete service and repair operation of a large repair facility. This person must use a wide range of abilities to coordinate the efforts of the shop supervisor, parts specialist, service writer, service dispatcher, and other shop personnel. The service manager must also handle customer complaints, answer questions, and ensure that the technicians are providing quality service for their customers.

Other Automotive Careers

There are numerous other automotive careers that do not require extensive mechanical ability. They do, however, require a sound knowledge of automotive technology. A few of these careers are discussed below.

An ***auto parts specialist*** must have a general knowledge of the components and systems of a vehicle. This person must be able to use customer requests, parts catalogs, price lists, and parts interchange sheets to quickly and accurately find needed parts.

A ***service writer,*** or ***service advisor,*** prepares work orders for vehicles entering the shop for repair or service. This person greets customers and listens to descriptions of their problems. The service writer must then fill out the repair order, describing what might be wrong.

A ***service dispatcher*** must select, organize, and assign technicians to perform each auto repair. The dispatcher must also keep track of all the repairs taking place in the shop.

An ***auto salesperson*** informs potential buyers of the features and equipment on a vehicle while trying to make a sale. By understanding how a vehicle works, the salesperson will be better prepared to answer questions. Positions are also available selling automotive-related parts and equipment, **Figure 2-6.**

An ***automotive designer*** has art training and can make sketches or models of new body and part designs. This person is employed by automobile or automotive part manufacturers, **Figure 2-7.**

Figure 2-6. A convention allows manufacturers of parts, tools, and equipment to display new and established products. People well versed in automotive technology and sales are needed to work at these events.

An ***automotive engineer*** designs new and improved automotive systems and parts. This person must use math, physics, and other advanced technologies to improve automotive designs. An engineer is a highly

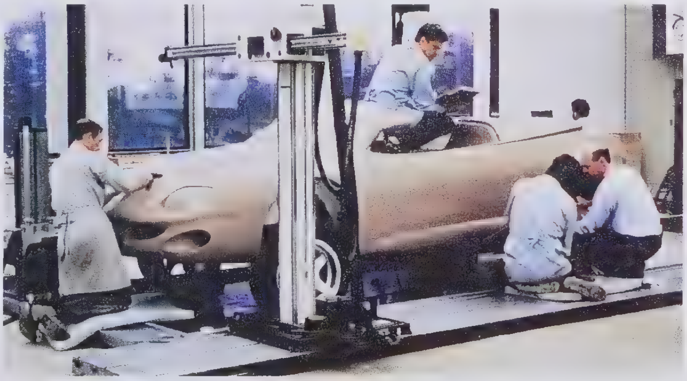

Figure 2-7. Automotive designers must have extensive engineering knowledge and a strong art background to design buildable yet aesthetically pleasing vehicles. (Pontiac)

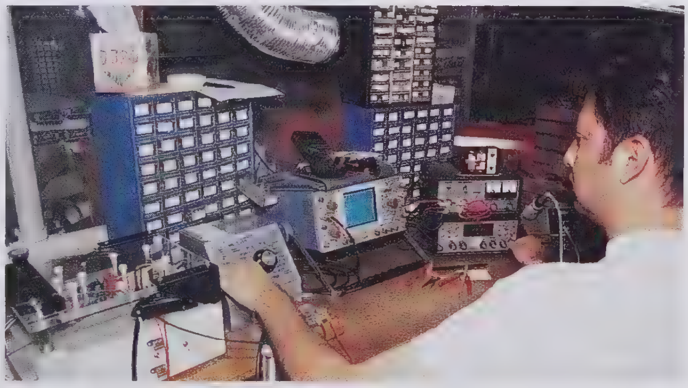

Figure 2-8. Automotive engineers normally have a bachelor's degree in a related engineering discipline. A working knowledge of automotive technology is a must for the engineer. (MSD Ignitions)

Figure 2-9. An automotive instructor must have a strong background in automotive technology and must also be able to communicate well. (Ford)

paid, college-trained individual with a working knowledge of the entire automobile, **Figure 2-8.**

Automotive instructors are experienced technicians capable of sharing their knowledge effectively. In addition to on-the-job experience, most instructors are required to have a college degree, **Figure 2-9.**

There are dozens of other job titles in the automotive field. Check with your school guidance counselor for more information. The chart in **Figure 2-10** shows automotive job opportunities. Trace the flow from manufacturer to service technician.

Automatic transmissions and transaxles
Engine repair
Electrical/electronic systems
Engine performance

Figure 2-10. Note the many positions available in the automotive field. (Florida Dept. of Voc. Ed.)

Tech Tip!
Many people start their careers as automotive technicians and then move to other related job areas. Never limit your sights on the future. Always try to improve your skills and potential for a new and better job.

Preparing for a Career in Automotive Technology

A career as an automobile technician can be quite challenging. Late-model cars and light trucks are very complex. They are constantly being updated and redesigned. This makes it difficult to keep up with the latest technology.

Many of the basic skills needed to succeed in automotive technology are learned in the classroom. Automobile technicians must have above-average math and English skills. They must be proficient at working with numbers to calculate part clearances and fill out work orders. They must also have good verbal skills to effectively communicate with customers and other technicians.

Many schools offer ***cooperative training programs.*** These programs allow you to earn school credit and a wage by working in a commercial repair shop. The employer gets a tax credit while helping the student technician learn the trade. Ask your guidance counselor or automotive instructor about a possible cooperative training program in your school.

On-the-Job Traits

Although automotive technicians are valued for their technical skills, employers look for other traits, as well. When you accept employment, you take on responsibilities beyond basic technical skills. These responsibilities include:

- *Reliability*, which means attending work regularly and arriving on time. Unreliable workers hurt themselves and other workers. Customers will be unhappy when their car or truck is not done on time because of unreliable workers.
- Maintaining a *positive attitude,* which means maintaining a cheerful outlook concerning other coworkers and about the job. If you are happy and think positive, you will do better work.
- *Productivity* means that you are able to get a lot of work done while maintaining quality. You are paid to work; use your time effectively. If you are not productive, you and your employer will make less money.
- *Following orders* means doing what the boss tells you to do. Someone must be in charge. You must assume that management knows how the job should be done. If you fail to follow orders, you will not have the job very long.
- *Pride* means looking and working like a professional. Come to the job in clean clothes and be well groomed. Also keep your tools and work area clean. This instills confidence in the customer. If you look sloppy, it implies your work is sloppy!
- *Congeniality* means getting along with co-workers. In a way, you live with your co-workers eight hours a day. If you get along with them, they will help you with tough jobs and make your life easier. If you argue with co-workers, everyone will suffer.

ASE Certification

The ***National Institute for Automotive Service Excellence,*** or ASE, is a nonprofit, *nonaffiliated* (no ties to industry) organization formed to help ensure the highest standards in automotive service.

ASE directs an organized testing and certification program under the guidance of a 40-member board of directors. The members of this board represent all aspects of the automotive industry—educators, shop owners, consumer groups, government agencies, aftermarket parts distributors, auto manufacturers, etc. This broad group of experts guides the ASE certification program and helps ASE stay in touch with the needs of the industry.

ASE certification is a program in which persons take written tests to prove their knowledge of automotive technology. ASE certification tests are voluntary. They do not have to be taken, and they do not license technicians.

Some countries have made technician certification a requirement. In the United States, however, technicians take the tests for personal benefit and to show their employers and customers they are fully qualified to work on a system of a car or an engine.

Over 500,000 technicians have passed ASE certification tests. Thousands of these technicians have been retested and recertified after five years to maintain their credentials.

Test Categories

In automotive technology, there are eight test categories: Engine Repair, Automatic Transmission/Transaxle, Manual Drive Train and Axles, Suspension and Steering, Brakes, Electrical Systems, Heating and Air Conditioning, and Engine Performance.

You can take any one or all of these tests. However, only four tests (200 questions maximum) can be taken at one testing session.

There are also seven medium/heavy truck tests, five collision repair and refinish tests, three engine machinist tests, and one advanced engine performance test. **Figure 2-11** provides a breakdown of each automotive test.

Certification Status

ASE-certified automobile technician status is granted for each ASE test passed. ***ASE-certified master automobile technician*** status, previously called certified general technician status, is granted when all eight automobile tests have been passed.

Sleeve or shirt patches and certificates are awarded for each test passed. This will let your customers know that you are fully capable of repairing their vehicles. See **Figure 2-12.**

Tech Tip!

Become a certified automobile technician! If you master the material in this textbook, you should have no trouble passing all the ASE certification tests. As an ASE-certified technician, you will gain added respect from your employer and your customers.

Figure 2-12. If you become certified, your customers and your employer will know that you are prepared to properly repair cars and light trucks. (ASE)

Test title:	Test content:	
Engine repair (80 questions)	TEST A1	Valve train, cylinder head, and block assemblies; lubricating, cooling, ignition, fuel, exhaust, and battery and starting systems
Automatic transmission/transaxle (50 questions)	TEST A2	Controls and linkages; hydraulic and mechanical systems
Manual drive train and axles (40 questions)	TEST A3	Manual transmissions, clutches, front and rear drive systems
Suspension and steering (40 questions)	TEST A4	Manual and power steering, suspension systems, alignment, and wheels and tires
Brakes (55 questions)	TEST A5	Drum, disc, combination, and parking brake systems; power assist and hydraulic systems
Electrical/electronic systems (50 questions)	TEST A6	Batteries; starting, charging, lighting, and signaling systems; electrical instruments and accessories
Heating and air conditioning (50 questions)	TEST A7	Refrigeration, heating and ventilating, AC controls
Engine performance (70 questions)	TEST A8	Oscilloscopes and exhaust analyzers; emission control and charging systems; cooling, ignition, fuel and carburetion, exhaust, and battery and starting systems

Figure 2-11. To become certified in a given automotive service area, you must pass the certification test for that area and have two years of related work experience. To become a master technician, you must pass all eight tests. (ASE)

Applying for ASE Tests

Anyone may take the ASE tests; however, a passing grade does not lead to automatic certification. To receive certification, the applicant must also have at least two years of experience as an automobile or truck technician. This experience does not have to be in any specific area of automotive service. In some cases, training programs, apprenticeship programs, or time spent performing similar work can be substituted for all or part of the work experience.

In some cases, formal training can be substituted for all or part of the experience requirement:

- High school training for three full years in automotive technology can be substituted for one year of work experience.
- Post-high school training for two years in a public or private facility can be substituted for one year of work experience.
- Two months of short training courses can be substituted for one month of work experience.
- Three years in an apprenticeship program can be substituted for two years of work experience.

To have schooling substituted for work experience, you must include a copy of your transcript (list of courses taken) or a certificate verifying your training or apprenticeship with your registration form and fee payment. Each should give your length of training and subject area.

To apply to take ASE tests, begin by acquiring a registration booklet. The registration booklet contains the proper registration form and all the information needed to complete the form. When you receive the form, fill it out carefully. To obtain a registration booklet, send your name and address to:

ASE Registration Booklet
101 Blue Seal Drive, S.E.
Leesburg, VA 20175

You can also register by phone at 1-877-564-8661 or online at www.asecert.org.

ASE tests are given in the spring and the fall of each year. The tests are usually held during a two-week period and are given on weeknights and Saturdays. The tests are given at designated test centers at over 300 locations in the United States.

Consult the ASE Information Bulletin for test locations. Be sure to determine the closest test center and record its number in the appropriate space on the application form. Most test centers are located at local colleges, high schools, or vocational schools.

When submitting the application, you must include a check or money order to cover all necessary fees. A fee is charged to register for the test series, and a separate fee is charged for each test taken. Refer to the latest ASE Information Bulletin for the current fee structure. In some cases, employers pay the registration and test fees. Check with your employer before submitting your application.

After receiving your application and fees, ASE will send you an admission ticket to the test center. You should receive the ticket by mail about two weeks after submitting your application.

Test-Taking Techniques

Follow all instructions given by the test administrators. During the test, read each question carefully before deciding on a proper answer. You must select the *most correct* response. Sometimes more than one response is correct. However, one answer will always be more correct than the others.

You will not be required to recall exact specifications unless they are general and apply to most makes and models of cars. For example, compression test pressure readings and engine clearances are typically about the same for all gasoline engines. This type of general information might be needed to answer some questions.

After completing all the questions in a particular test, recheck your answers to ensure that you did not make a careless error. In most cases, rechecking your answers more than once is unnecessary and may lead you to change correct answers to incorrect ones. The time allowed for each test is usually about four hours. However, you may leave after completing your last scheduled test and handing in all test material.

A few tips that might help you pass ASE certification tests include:

- Read the statements or questions slowly. You might want to read through them twice to make sure you fully understand the questions.
- Analyze the statement or question. Look for hints that make some of the possible answers wrong.
- Analyze the question as if you were the technician trying to fix the car. Think of all possible situations and use common sense to pick the most correct response.
- When two technicians give statements concerning a problem, try to decide if either is incorrect. If both are valid statements about a situation, choose the answer stating that both technicians are correct. If only one is correct or neither is correct, mark the answer accordingly. This is one of the most difficult types of questions.

- If the question gives only limited information, make sure you do not pick one answer as correct because it describes a more common condition. If the question does not let you conclude that one answer is better than another, both answers are equally correct.
- Your first thought about which answer is correct is usually the correct response. If you think about a question too much, you may read something into the question that is not there. Read the question carefully and make a decision.
- Do not waste time on any one question. Make sure you have enough time to answer all the questions on the test.
- Visualize yourself performing a test or repair when trying to answer a question. This will help you solve the problem more accurately.

Types of ASE Test Questions

ASE tests are designed to measure your knowledge of three things:

- The operation of various automotive systems and components.
- The diagnosis and testing of various automotive systems and components.
- The repair of automotive systems and components.

All test questions are multiple choice and contain four possible answers. Sample questions are given below. The answer to each question is explained in detail.

One-Part Questions

In a one-part question, you must choose the best answer out of all the possibilities.

1. Which of the following components ignites the fuel in a gasoline engine?
   (A) Injector.
   (B) Valve.
   (C) Spark plug.
   (D) Glow plug.

The spark plug produces the electric arc to start the fuel burning. Therefore, the correct answer is *(C) Spark plug*. The injector simply sprays fuel into the engine. The valve allows the air-fuel mixture to flow into the engine. The glow plug is only used in a diesel engine to warm the combustion chamber to aid combustion.

Two-Part Questions

Two-part questions require you to read two statements and decide if they are true. Both statements can be true or both can be false. In some cases, only one of the statements is true.

1. Technician A says a locking rear differential assembly can be refilled with regular gear oil. Technician B says the differential assembly allows the vehicle to turn corners without wheel hop. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A & B.
   (D) Neither A nor B.

In this question, the statement made by Technician A is wrong. A locking rear wheel differential assembly must be refilled with special nonslip oil. Technician B's statement is correct, since the purpose of the differential assembly is to allow the vehicle to turn corners without wheel hop. Therefore, the correct answer is *(B) B only.* Note that Technician A and Technician B appear in many ASE test questions. You must carefully evaluate the statements of each technician before deciding which answer is correct.

Negative Questions

Some questions are called negative questions. These questions require you to identify the *incorrect* answer. Negative questions will usually contain the word *"except."*

1. An engine contains all of the following bearings *except:*
   (A) connecting rod bearings.
   (B) main crankshaft bearings.
   (C) camshaft bearings.
   (D) reverse idler bearings.

Since reverse idler bearings are used in transmissions and there is no bearing with that name used in the engine, the correct answer is *(D) reverse idler bearings.*

A variation of the negative question contains the word *"least."*

1. An automatic transmission installed in a late-model vehicle slips during acceleration. Which of these defects is *least* likely to be the cause?
   (A) Clogged transmission oil filter.
   (B) Defective transmission oil pump.
   (C) Maladjusted throttle linkage.
   (D) Low fluid level.

In this case, the least likely cause of transmission slippage is a maladjusted throttle linkage, which is much more likely to cause shifting problems than slippage. Therefore, the correct answer is *(C) Maladjusted throttle linkage.*

Completion Questions

Some test questions are simply sentences that must be completed. One of the four possible answers correctly completes the sentence.

1. A torque wrench is used to measure:
    (A) *twisting force on fasteners.*
    (B) *shear applied to fasteners.*
    (C) *horsepower applied to fasteners.*
    (D) *transmission slip yoke angles.*

Once again, the question calls for the best answer. The torque wrench is used to measure twisting force, or torque, so *(A) twisting force on fasteners* is correct.

Test Results

The results of your test will be mailed to your home. Only you will find out how you did on the tests. You can then inform your employer if you like.

Test scores will be sent out a few weeks after you have completed the test. If you pass a test, you can consider taking more tests. If you fail, you will know that more study is needed before retaking the test.

Recertification Tests

Once you are certified in any area, you must take a *recertification test* every five years to maintain your certification. Recertification test questions concentrate on recent developments. This ensures that certified technicians will keep up with changes in technology.

Applying to take recertification tests is similar to applying for original certification tests. Use the same form and enclose the proper recertification test fees. If you allow your certification to lapse, you must take the regular certification test(s) to regain your certification.

Text Organization and ASE Certification

This textbook will help you prepare for ASE certification. The content, scope, and organization were developed with the ASE certification tests in mind. Each chapter contains a section of ASE-type questions, which will help you pass the ASE certification tests. Additionally, sample ASE tests are presented at the ends of applicable sections.

Entrepreneurship

An ***entrepreneur*** is someone who starts a business, such as a muffler shop, tune-up shop, parts house, or similar facility. To be a good entrepreneur, you must be able to organize all aspects of the business: bookkeeping, payroll, facility planning, hiring, etc. After gaining several years of on-the-job experience, you might want to consider starting your own business.

Most successful entrepreneurs have a quality known as leadership. Effective leaders have the courage to set a course of action and get the cooperation of others in meeting goals. Leaders are willing to accept responsibility for their actions. If their decisions show signs of failure, they take action to correct mistakes. If their decisions are good, they are willing to share the "glory." Good leaders readily credit the work of others who have contributed to the success of the business venture.

Workplace Skills

The automotive industry is one of the largest industries in the United States. A wide variety of jobs and career fields are available within the automotive industry. As you study automotive technology, keep other automotive-related professions in mind. You might enjoy sales more than the service field. Nevertheless, your knowledge of automotive technology will make you a better employee in any field in the automotive industry.

Summary

- Economists are predicting a continued demand for automotive technicians for many years.
- An automotive technician makes a living by diagnosing, servicing, and repairing cars and light trucks.
- A job as a service station attendant requires little mechanical experience, yet provides an excellent learning experience.
- One way to get started in automotive service is to become an apprentice or helper mechanic, working under an experienced technician.
- A specialized technician is an expert on one system of a car. This type of specialist may work only on brakes, transmissions, engines, tune-ups, electrical systems, or air conditioning.
- An engine technician must be able to troubleshoot, service, and repair automobile engines.
- A transmission technician usually works on automatic and manual transmissions, transaxles, clutches, and, sometimes, rear axle assemblies.
- A steering and suspension technician is responsible for checking, replacing, and adjusting steering and suspension components.

- A brake technician specializes in brake system service and repair.
- The electrical system technician must be able to test and repair lighting systems, charging systems, computer control systems, and starting systems.
- The driveability and performance technician must test and adjust engine fuel, ignition, and emission systems.
- A master technician is an experienced professional who has mastered *all* specialized areas and is capable of working on almost any part of a vehicle.
- A shop supervisor is in charge of other technicians in a large garage.
- An entrepreneur is someone who starts a business. This might be a muffler shop, tune-up shop, parts house, or similar facility.
- Auto technician certification is a program where persons voluntarily take written tests to prove their knowledge as an auto technician.

Review Questions—Chapter 2

Please do not write in this text. Place your answers on a separate sheet of paper.

1. List four skills that may be needed when working as an automotive technician.
2. Which of the following is *not* a typical specialized technician?
   (A) Engine technician.
   (B) Steering and suspension technician.
   (C) Brake technician.
   (D) Drive shaft technician.
3. Describe some of the responsibilities of a driveability and performance technician.
4. A(n) _____ specialist may have to do grease jobs.
5. What is a master technician?
6. Explain the job of a service manager.
7. What is a cooperative training program?
8. List the eight test categories of ASE certification.
9. You will receive a(n) _____ and a(n) _____ for each ASE certification exam passed.
10. A(n) _____ is an individual who starts a business.

ASE-Type Questions

1. Technician A says that an automotive technician must be a "jack of all trades." Technician B says that the technician's job is seldom boring. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. All the following are automatic benefits of ASE certification *except:*
   (A) recognition.
   (B) a sleeve patch.
   (C) a pay raise.
   (D) a wall certificate.
3. A vehicle comes into the shop for repairs. Technician A says to check with the service writer for the details of the customer complaint. Technician B says to check with the shop supervisor to get information on the complaint. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. A used car needs a wheel alignment. Which technician would usually complete this operation?
   (A) Engine technician.
   (B) Steering and suspension technician.
   (C) Wheel technician.
   (D) Brake technician.

5. Technician A says some ASE questions cover the operation of various automotive systems and components. Technician B says some ASE questions cover the repair of various automotive systems and components. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Activities—Chapter 2

1. Research an automotive career of your choice; using a computer or a typewriter, prepare a written report covering such topics as duties, working conditions, pay range, and opportunities for advancement.
2. Interview a manager of a parts department for a local garage. Report on the duties performed.

3

Basic Hand Tools

After studying this chapter, you will be able to:

- Identify common automotive hand tools.
- List safety rules for hand tools.
- Select the right tool for a given job.
- Maintain and store tools properly.
- Use hand tools safely.
- Correctly answer ASE certification test questions referring to hand tools.

Professional auto technicians invest thousands of dollars on tools, and for good reason. It is almost impossible to do even the simplest auto repair without using some type of tool. Tools serve as extensions to parts of the human body. They increase the physical abilities of fingers, hands, arms, legs, eyes, ears, and back. A well-selected set of tools speeds up repairs, improves work quality, and increases profits.

This chapter will cover the basic hand tools commonly used in the shop. Specialized hand tools are covered in later chapters. Use the index to locate these tools as needed.

Tech Tip!
It is very frustrating trying to fix a vehicle without the right tools. It can be like trying to "fight a forest fire with a squirt gun"—*impossible!* Invest in a complete set of quality tools.

Tool Rules

There are several basic tool rules that should be remembered. These are as follows:

- Purchase quality tools—With tools, you usually get what you pay for. Quality tools are lighter, stronger, easier to use, and more dependable than off-brand, bargain tools. Many manufacturers of quality tools provide guarantees. Some are for the lifetime of the tool. If the tool fails, the manufacturer will replace it free of charge. This can save money in the long run.
- Keep tools organized—A technician has hundreds of different tools. For the tools to be located quickly, they should be neatly arranged. There should be a place for every tool, and every tool should be in its place. If tools are just thrown into the toolbox, time and effort are wasted "digging and searching" instead of fixing the vehicle.
- Keep tools clean—Wipe tools clean and dry after each use. A greasy or oily tool can be dangerous! It is very easy to lose a grip on a dirty tool, cutting or breaking a finger or hand.
- Use the right tool for the job—Even though several different tools may be used to loosen a bolt, usually one will do a better job. It may be faster, grip the bolt better, be less likely to break, or require less physical effort. A good technician knows when, where, and why a particular tool will work better than another. Keep this in mind as you study automotive tools.

Tech Tip!
The time spent maintaining your tools and toolbox is time well spent. Well-organized tools will save time on each job and help you get more work done. Unorganized or poorly maintained tools will hurt your on-the-job performance.

Tool Storage

A ***toolbox*** stores and protects a technician's tools when not in use. There are three basic parts to a typical toolbox, **Figure 3-1.** These include:

- A large lower roll-around cabinet.
- An upper tool chest that sits on the roll-around cabinet.

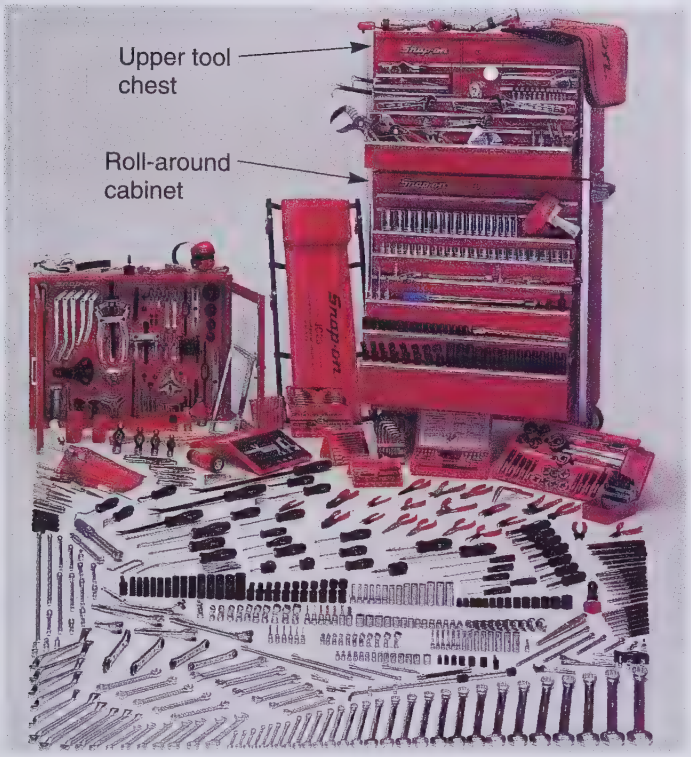

Figure 3-1. A toolbox is used to organize the wide variety of tools a technician needs. (Snap-on Tool Corp.)

- A small carrying tray. This is usually placed in the upper tool chest.

The ***lower roll-around cabinet*** holds the bulky, heavy tools. Large power tools are normally kept in this part of the box. Extra storage compartments can be bolted to the sides of the roll-around cabinet.

Commonly used tools are normally placed in the ***upper tool chest.*** Being near eye level, tools can be easily seen and reached without bending. This saves time and energy, and increases production.

The small ***carrying (tote) tray*** is for holding frequently used tools that are carried to the job. For example, if a technician frequently does brake repairs, all the special brake tools can be kept in the tray and taken to the vehicle more easily.

Toolbox Organization

Related tools are normally kept in the same toolbox drawer. For example, various types of hammers may be stored in one drawer and all screwdrivers in another. Small or delicate tools should *not* be kept with large, heavy tools to prevent damage. ***Tool holders*** help organize small tools. These include small clip or magnetic racks, cloth or plastic pouches, or socket trays. They are often used to protect tools and to keep them organized by size. Holders also allow a full set of tools to be taken to the job.

Warning!
Never open several toolbox drawers at one time. If you do, the heavy toolbox might flip over. Serious injury can result since a toolbox can weigh up to 1000 pounds. Close each drawer before opening the next.

Wrenches

Wrenches are used to install and remove nuts and bolts. ***Wrench size*** is determined by measuring across the wrench jaws. Refer to **Figures 3-2** and **3-3.** Wrenches come in both conventional (inch) and metric (millimeter) sizes. The size is stamped on the side of the wrench. Here are a few wrench rules to follow.

- Always select the right size wrench. It must fit the bolt head snugly. A loose-fitting wrench will round off the corners of the bolt head.
- Never hammer on a standard wrench to break loose a bolt. Use a longer wrench with more leverage or a special ***slug wrench.*** A slug wrench is designed to be used with a hammer.
- When possible, pull on the wrench. Then, if the wrench slips, you are less likely to hurt your hand. When you must push, use the palm of your hand and keep your fingers open.

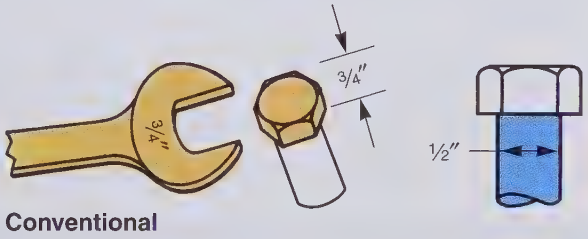

Figure 3-2. Conventional tool sizes are given in fractions of an inch. The measurement is the width of the jaw opening. As shown here, these sizes are *not* the same as bolt sizes. (Deere & Co.)

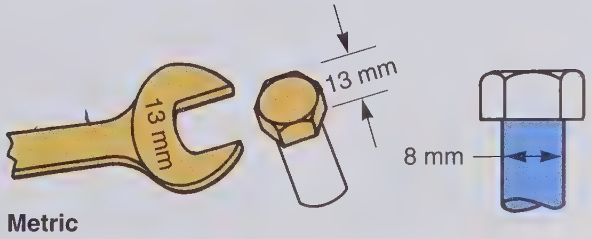

Figure 3-3. Metric wrench sizes given in millimeters. The measurement is the width of the jaw opening. The wrench size is *not* the same as the bolt size. (Deere & Co.)

- Never use a steel bar or pipe to increase the length of a wrench for leverage. Excess force can bend or break the wrench.

To be able to select the right wrench for the job, you must learn the advantages and disadvantages of each type. These advantages and disadvantages are covered in the next sections. Study the material carefully.

Open-End Wrenches

An ***open-end wrench*** has an open, or split, jaw on both ends. Each end is a different size and set at an angle, **Figure 3-4A.** This angle allows the open-end wrench to turn bolts and nuts with little wrench swing space. The wrench can be turned over between each swing to get a new "bite" on the bolt head. An open-end wrench has weak jaws. It should *not* be used on extremely tight nuts or bolts. Its jaws will flex outward and round off the bolt head.

Box-End Wrenches

Box-end wrenches are completely closed on both ends. They fully surround and grip the head of a bolt or nut, **Figure 3-4B.** A box-end wrench will not round off bolt heads as easily as an open-end wrench. Box-end wrenches are available with either 6- or 12-point openings. A 6-point opening is the strongest configuration. It should be used on extremely tight, rusted, or partially rounded bolt or nut heads.

Combination Wrenches

A ***combination wrench*** has a box-end jaw on one end and an open-end jaw on the other, **Figure 3-4C.** Both ends are usually the same size. A combination wrench provides the advantage of two types of wrenches for the price of one.

Line Wrenches

A ***line wrench,*** also called a ***tubing wrench*** or ***flare nut wrench,*** is a box-end wrench with a small opening or split in the jaw, **Figure 3-4D.** The opening allows the wrench to be slipped over fuel lines, brake lines, or power steering lines and onto the fitting nut. A line wrench prevents damage to soft fittings.

Socket Wrenches

A ***socket*** is a cylinder-shaped, box-end tool for removing or installing bolts and nuts. See **Figure 3-5.** One end fits over the fastener. The other end has a square hole that fits on a handle used for turning.

A socket's ***drive size*** is the size of the square opening for the ratchet or tool handle. As pictured in **Figure 3-6,**

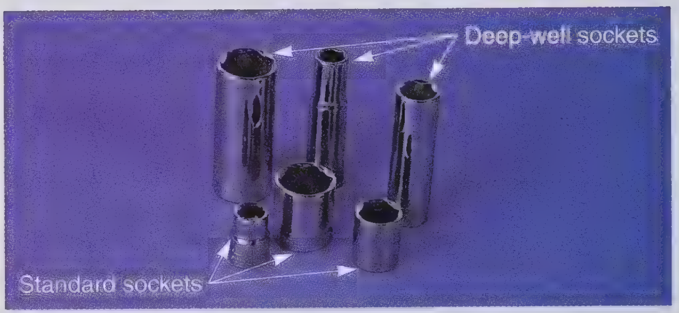

Figure 3-5. Different socket types. Note that both standard and deep-well sockets are shown.

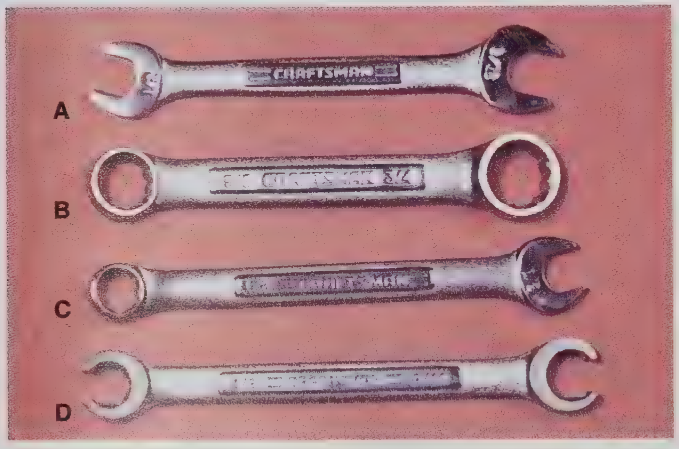

Figure 3-4. The four basic types of hand wrenches. A—Open-end wrench. B—Box-end wrench. C—Combination wrench. D—Tubing or line wrench.

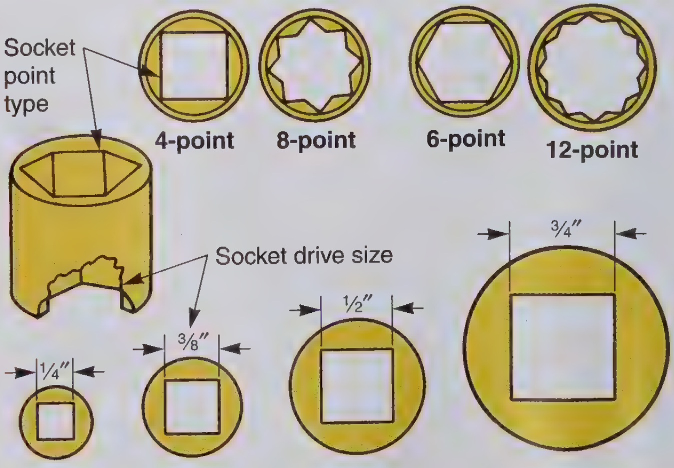

Figure 3-6. Sockets come in four drive sizes and four point types. The most commonly used drives are 3/8″ and 1/2″. The most common point types are 6-point and 12-point.

sockets come in four drive sizes: 1/4″, 3/8″, 1/2″, and 3/4″. They also come in four different points: 4-point, 6-point, 8-point, and 12-point.

If a small drive size is used on very large or tight fasteners, the socket or handle can be broken. A large drive may be too awkward for small nuts and bolt heads. Generally, a 1/4″ drive socket and handle should be used on bolt and nut heads 1/4″ and smaller. A 3/8″ socket set is adequate on bolt head and nut sizes between 1/4″ and 5/8″. A 1/2″ drive is strong enough to handle bolt or nut heads from 5/8″ to 1″. A 3/4″ drive is for bolts and nuts with a head size larger than 1″.

Socket Handles

Socket handles fit into the square opening in the top of the socket. Several types are shown in **Figure 3-7.** A ***ratchet*** is the most commonly used and versatile socket handle. It has a small lever that can be moved for either loosening or tightening bolts. A ***flex bar,*** or ***breaker bar,*** is the most powerful and strongest socket handle. It should be used when breaking loose large or extremely tight bolts and nuts. A ***speed handle*** is the fastest hand-operated socket handle. After a bolt is loosened, a speed handle will rapidly spin out the bolt.

Extensions are used between a socket and its handle. See **Figure 3-8A.** They allow the handle to be placed farther from the workpiece, giving you room to swing the handle and turn the fastener. A ***universal joint*** is a swivel that lets the socket wrench reach around obstructions, **Figure 3-8B.** It is used between the socket and drive handle, with or without an extension. Avoid putting too much bend into a universal joint, or it may bind and break.

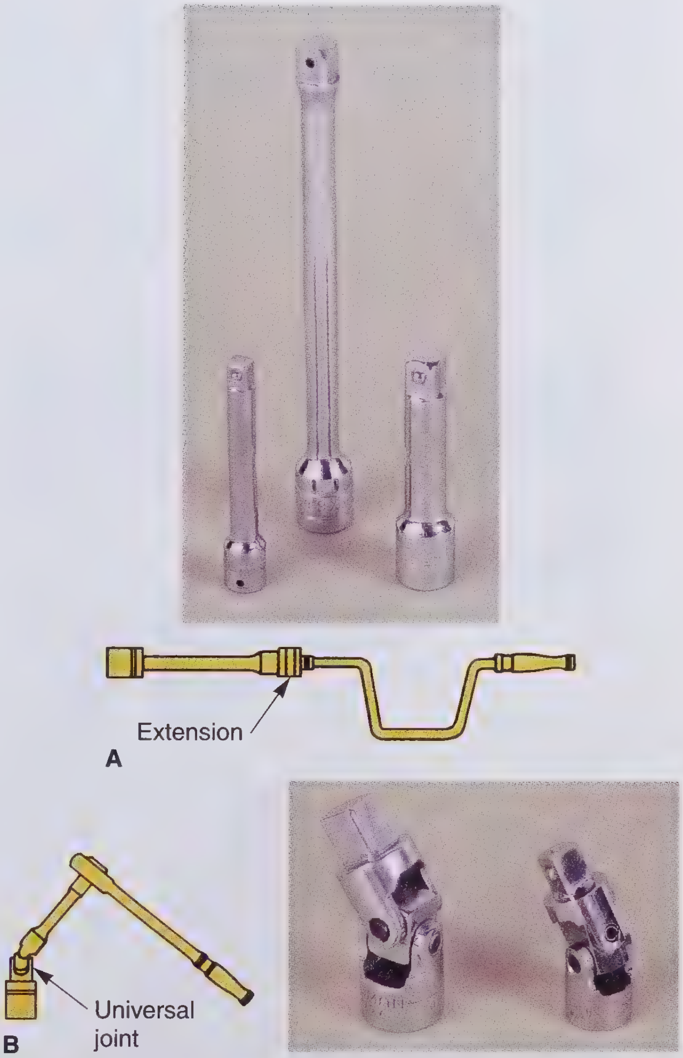

Figure 3-8. A—An extension moves the socket away from the handle for more clearance. B—A universal joint allows the socket to be turned from an angle.

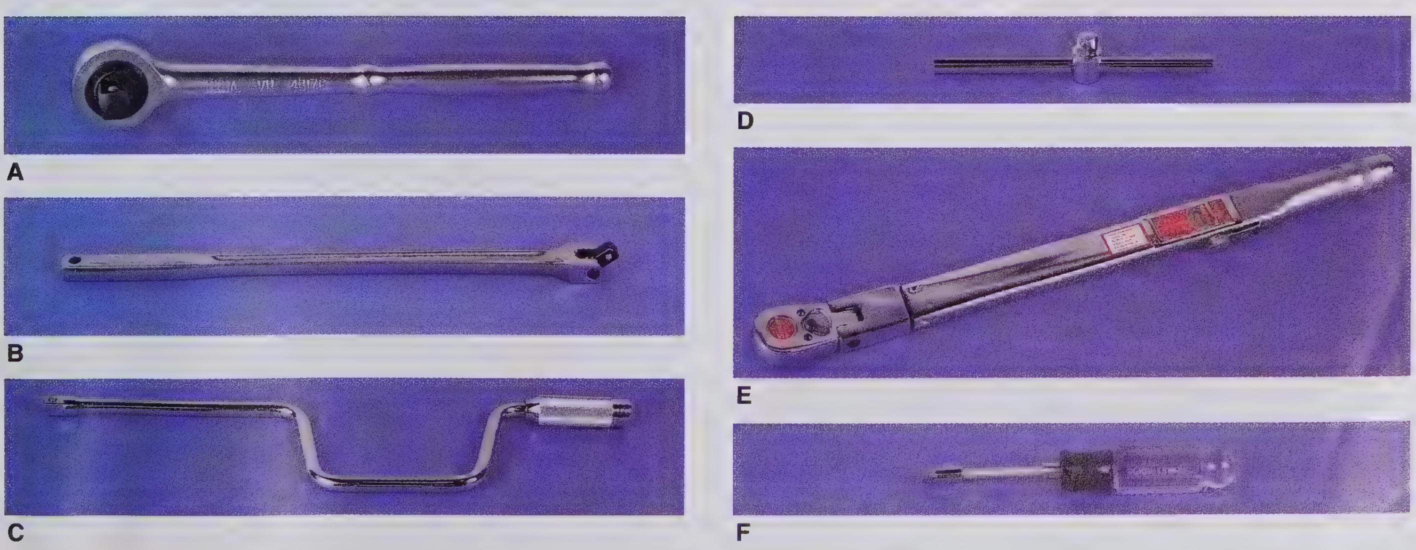

Figure 3-7. Various socket handles. A—Ratchet. B—Breaker bar or flex handle. C—Speed handle. D—T-handle. E—Torque wrench. F—Flexible driver.

Other Wrench Types

An ***adjustable wrench,*** or ***Crescent wrench,*** has jaws that can be adjusted to fit different size bolt and nut heads, **Figure 3-9A.** It should be used only when other type wrenches will *not* fit. An adjustable wrench is a handy tool to carry for emergencies. It is like having a full set of open-end wrenches.

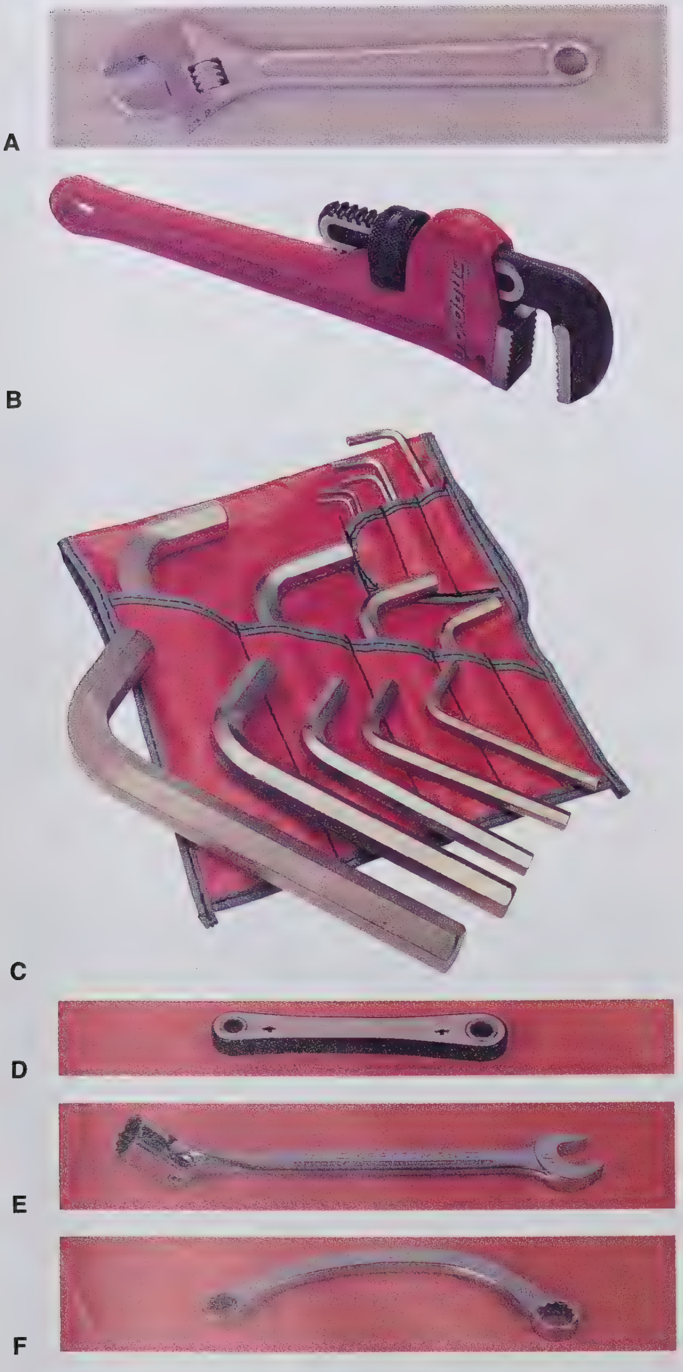

Figure 3-9. A—Adjustable, or Crescent, wrench. B—Pipe wrench. C—Allen, or hex, wrenches. D—Ratchet wrench. E—Flex-combination wrench. F—Half-moon, 12-point wrench for tight quarters. (Snap-on Tool Corp.)

A ***pipe wrench*** is an adjustable wrench used to grasp cylindrical objects. See **Figure 3-9B.** The toothed jaws actually dig into the object. For this reason, never use it on parts that will be ruined by marks or nicks.

An ***Allen wrench*** is a hexagonal (six–sided) shaft-type wrench, **Figure 3-9C.** It is used to turn set screws on pulleys, gears, and knobs. To prevent damage, make sure the Allen wrench is fully inserted in the fastener before turning.

There are several other types of wrenches. These are shown in **Figure 3-9.**

Screwdrivers

Screwdrivers are used to remove or install screws. They come in many shapes and sizes. A ***standard screwdriver*** has a single blade that fits into a slot in the screw head. See **Figure 3-10A.** A ***Phillips screwdriver*** has two crossing blades that fit into a star-shaped screw slot, **Figure 3-10B.** A ***Reed and Prince*** screwdriver is similar to a Phillips, but it has a slightly different tip shape,

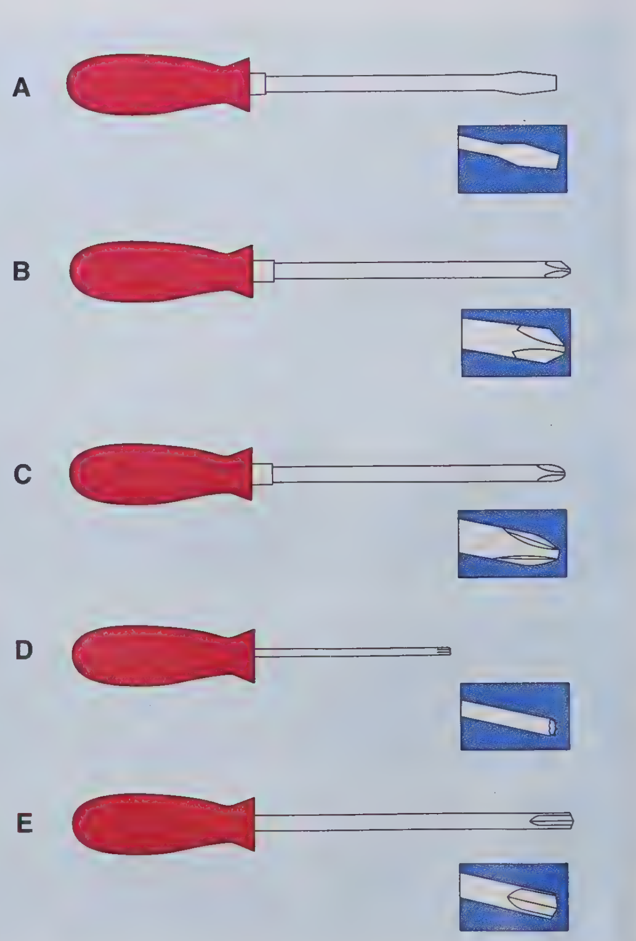

Figure 3-10. Screwdriver types. A—Standard. B—Phillips. C—Reed and Prince. D—Torx. E—Clutch. (Snap-on Tool Corp.)

Figure 3-10C. ***Torx*** and ***clutch head*** are special types of screwdrivers and are shown in **Figures 3-10D** and **E.**

Offset and ***stubby screwdrivers*** are good in tight places, **Figures 3-11A** and **B.** For example, a stubby screwdriver is needed for loosening screws inside a glove box. ***Starting screwdrivers*** hold the screw securely until started in its hole, **Figure 3-11C.** They prevent the screw from being dropped and lost. A ***scratch awl*** looks like a screwdriver, but it has a sharp, pointed tip, **Figure 3-12D.** It is used for marking sheet metal and other parts. An ***impact driver*** can be used to loosen extremely tight screws. When struck with a hammer, the driver exerts powerful turning and downward forces. This is shown in **Figure 3-12.**

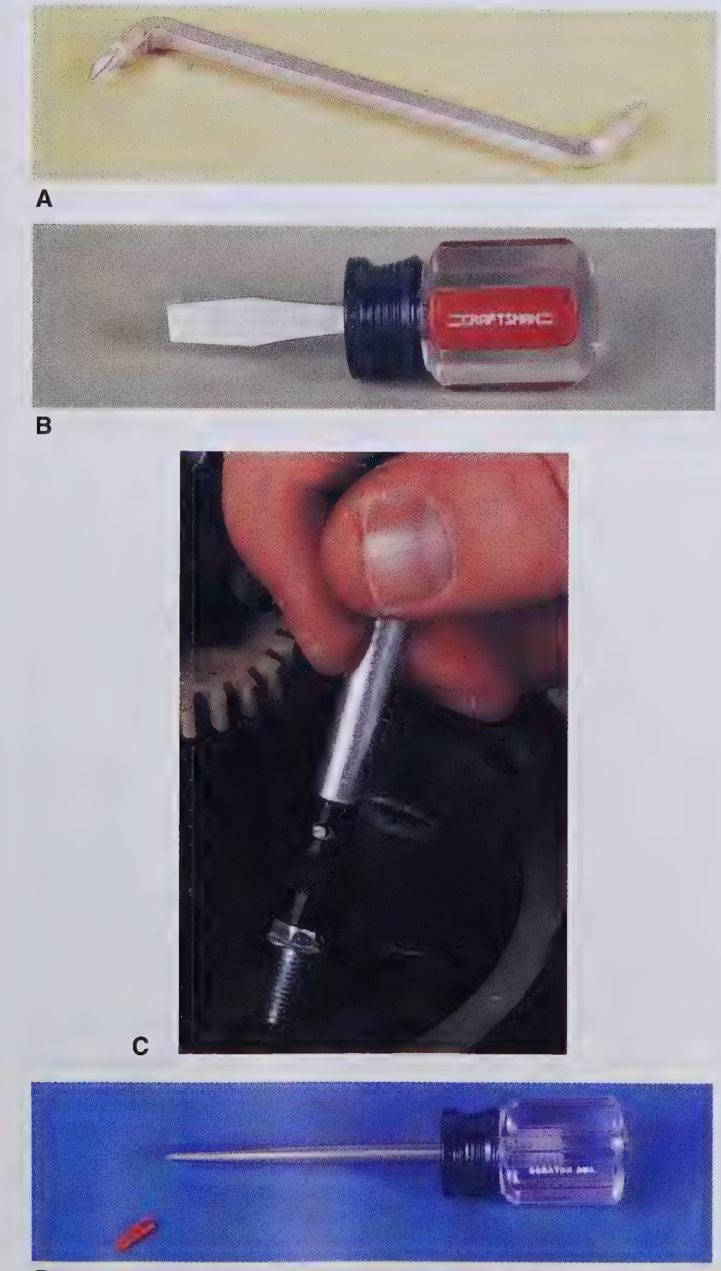

Figure 3-11. A—Offset screwdriver. B—Stubby screwdriver. C—Starting screwdriver. D—Scratch awl. It is similar to a screwdriver, but has a pointed tip for marking sheet metal and other parts.

When selecting a screwdriver, pick one that is wide and thick enough to *completely fill* the screw slot, **Figure 3-13.** If the screwdriver is too large or too small, damage to the screwdriver or screw may occur. Most screwdrivers are *not* designed to be hammered on or pried with. Only heavy-duty screwdrivers with a full shank can withstand *light* hammering and prying.

Pliers

Pliers are used to grip, cut, crimp, hold, and bend various parts. Different pliers are helpful for different situations. Several types of pliers are pictured in **Figure 3-14.** Never use pliers when another type tool will work. Pliers can nick and scar a part.

Combination pliers, or ***slip-joint pliers,*** are the most common pliers used by an automotive technician. The slip joint allows the jaws to be adjusted to grasp different size parts, **Figure 3-14A.** ***Rib joint pliers,*** also called ***channel lock pliers*** or ***water pump pliers,*** open extra wide for holding very large objects, **Figure 3-14B.**

Needle nose pliers are excellent for handling extremely small parts or reaching into highly restricted areas, **Figure 3-14C.** Do *not* twist too hard on needle nose pliers, or the long thin jaws can be bent.

Diagonal cutting pliers are the most commonly used cutting pliers, **Figure 3-14D.** Their jaw shape allows them to cut items flush with an adjacent surface. Diagonal cutting pliers are often used to cut off cotter pins, wires, and plastic ties.

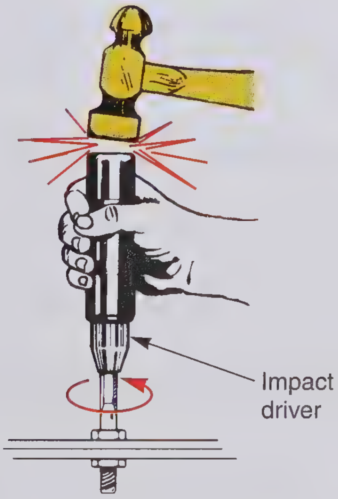

Figure 3-12. An impact driver loosens stubborn fasteners. Hit it with a hammer to free and turn the screw. (Lisle)

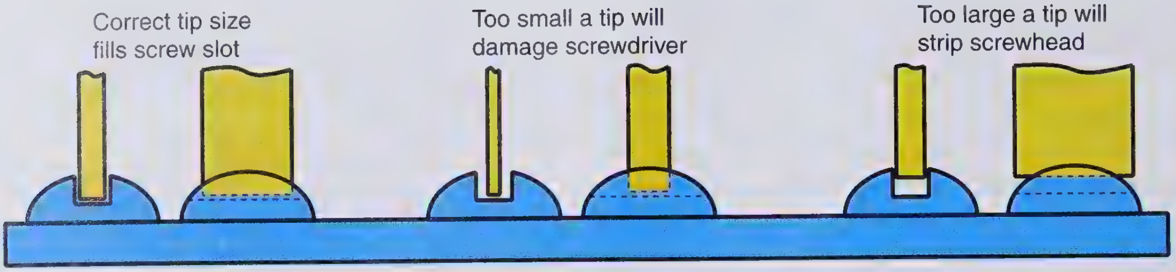

Correct tip size fills screw slot
Too small a tip will damage screwdriver
Too large a tip will strip screwhead

Figure 3-13. The screwdriver tip must fit in the slot perfectly. If not, the screwdriver and screw can be ruined.

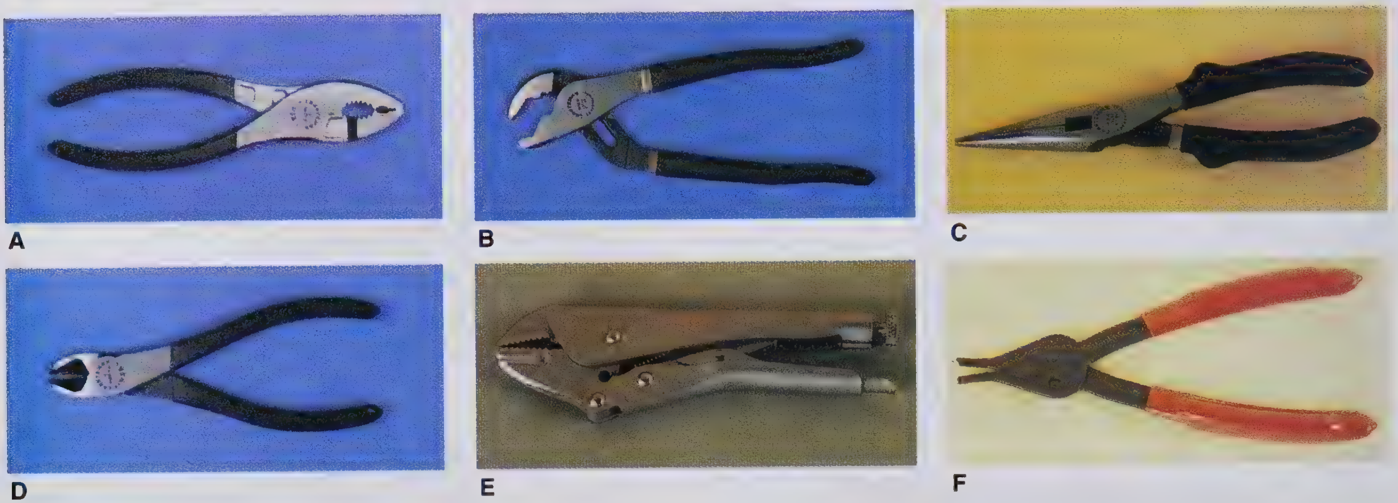

Figure 3-14. Different types of pliers. A—Slip joint. B—Rib joint. C—Needle nose. D—Diagonal cutting. E—Vise grips. F—Snap ring.

Locking pliers, or ***vise grips,*** clamp onto and hold a part, **Figure 3-14E.** This frees both hands to do other tasks. Because of their clamping power, vise grips can sometimes be used to unscrew fasteners with stripped or rounded heads. However, *never* use them on undamaged nuts or bolts. ***Snap ring pliers*** have sharp, pointed tips for installing and removing special clips called snap rings. A pair of snap ring pliers is shown in **Figure 3-14F.**

Hammers

Various types of hammers are used for operations that involve striking a tool or part. It is important to use the right hammer and to use it properly. Several hammers are shown in **Figure 3-15.** The following are some general rules governing hammers.

- Select the right size hammer. If a large part is struck by a small hammer, the hammer can fly backwards dangerously. If the hammer is too large, however, it may damage the part.
- Always check that the hammer head is tight on the handle. If not, the head may fly off and cause injury or damage.
- Use a brass, plastic, or dead blow hammer on parts and tools that can be damaged by a steel hammer. Use a steel hammer only when maximum driving force is required.
- Grasp the hammer near the end of the handle and strike the part or tool squarely.

A ***ball peen hammer*** is the most common type of hammer used in automotive work, **Figure 3-15A.** It has a flat face for general striking. It also has a round end for shaping metal parts, such as sheet metal or rivet heads.

A ***sledge hammer*** has a very large head, **Figure 3-15B.** It is usually the heaviest hammer and produces powerful blows. A sledge hammer is sometimes used to free frozen parts.

The ***brass*** has a soft, heavy head and is useful when scarring the surface of a part must be avoided, **Figure 3-15C.** The relatively soft head deforms to protect the part surface from damage.

A ***plastic*** or ***rawhide hammer*** is light and has a soft head, **Figure 3-15D.** It is used where light blows are needed to prevent part breakage or damage to surfaces on small and delicate parts.

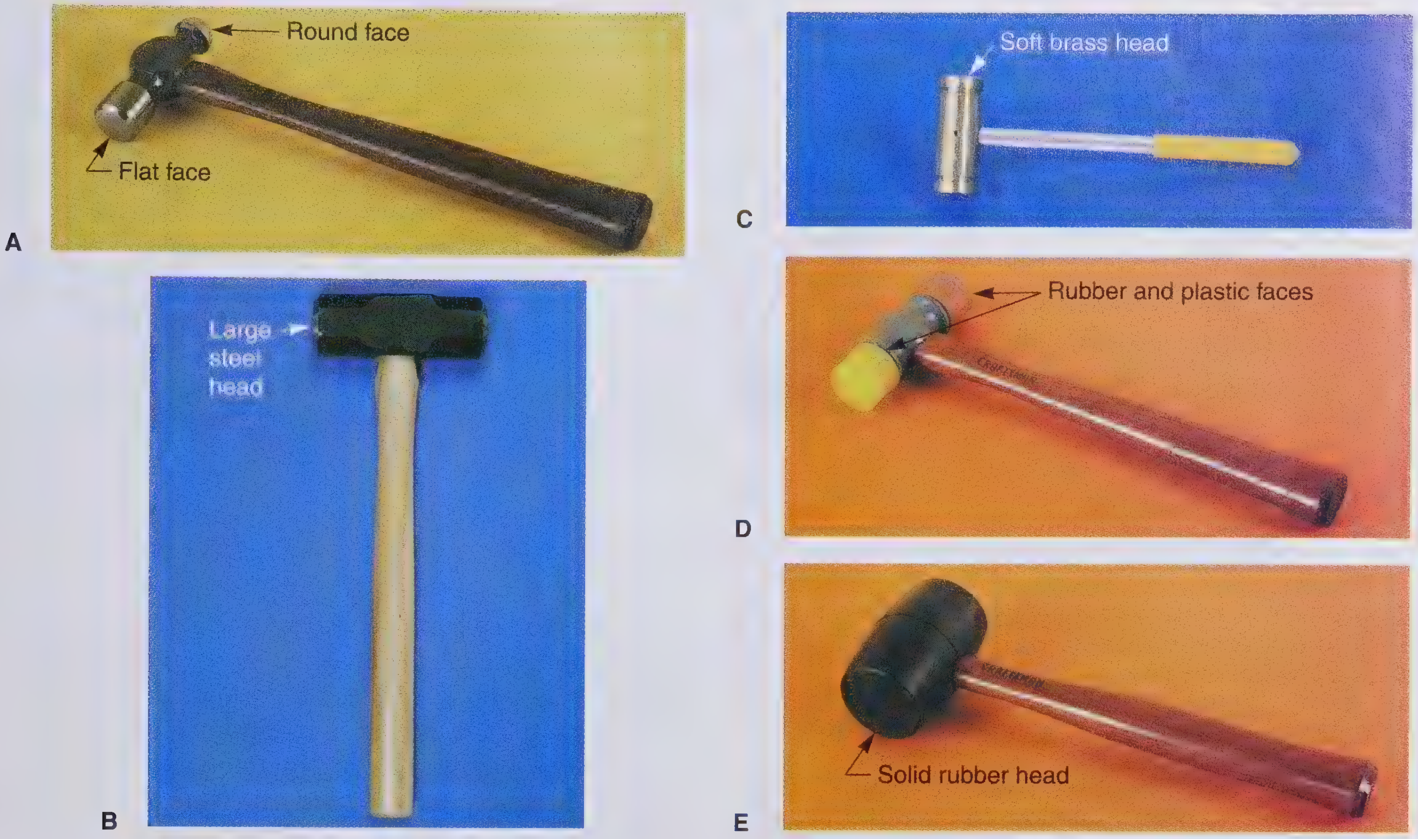

Figure 3-15. Different hammer types. A—Ball peen. B—Sledge. C—Brass. D—Plastic tipped. E—Rubber mallet.

A ***rubber mallet*** has a head made of solid rubber, **Figure 3-15E.** It will rebound, or bounce, upon striking and is not effective on solid metal parts. It is recommended on many sheet metal or plastic parts, such as garnish molding and wheel covers.

A ***dead blow hammer*** has a plastic-coated, metal face and is filled with small metal balls called lead shot. The extra weight prevents a rebound of the hammer when striking. The plastic coating prevents surface damage.

Chisels and Punches

Chisels are for cutting off damaged or badly rusted nuts, bolts, and rivet heads. There are various chisel shapes, **Figure 3-16.** Use common sense when selecting a chisel shape.

Punches also come in several configurations. See **Figure 3-16.** A ***center punch*** is frequently used to mark parts for reassembly and to start a hole before drilling. Look at **Figure 3-17.** The indentation made by a center punch will keep a drill bit from moving when first starting to drill.

A ***starting punch,*** or ***drift punch,*** has a shank tapered all the way to the end. It is strong and can withstand moderate blows. It is used to drive pins, shafts, and metal rods partway out of a hole. A ***pin punch*** has a straight shank

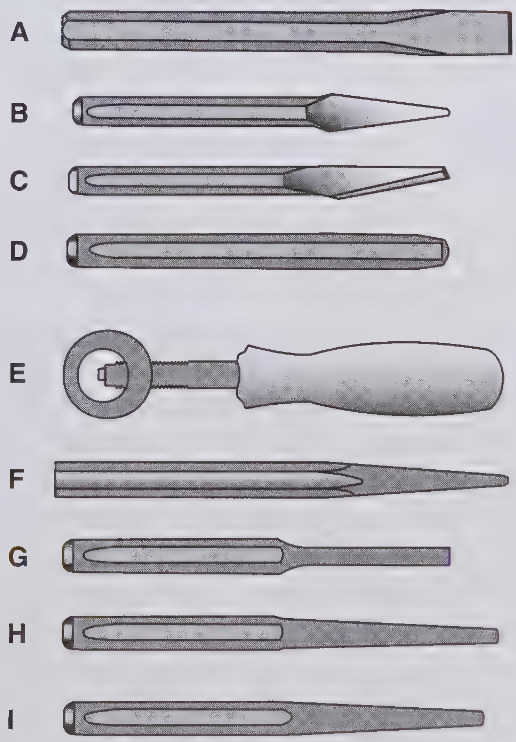

Figure 3-16. Different chisels and punches. A—Flat chisel. B—Cape chisel. C—Round-nose cape chisel. D—Diamond-point chisel. E—Chisel or punch holder. F—Center punch. G—Pin punch. H—Long, tapered punch. I—Starting punch. (Snap-on Tool Corp. and Proto Tools)

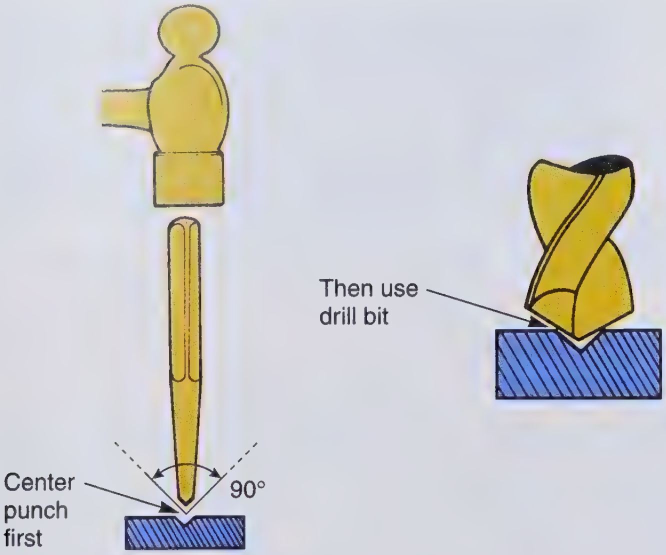

Figure 3-17. A center punch makes a small indentation in metal parts. This can then be used to start a drill bit. (Florida Dept. of Voc. Ed.)

and is lighter than a starting punch. It is used *after* a starting punch to push a shaft or rod the rest of the way out of a hole.

An ***aligning punch*** has a long, tapered shaft and is handy for lining up parts during assembly. An aligning punch can be inserted into holes in mating parts and then wiggled to match up the holes. Never use an aligning punch as a center punch. Its tip is too soft and would be ruined.

Remember these chisel and punch rules:

- Use the largest punch or chisel that will work. If a small punch is used on a very large part, the punch can rebound and fly out with tremendous force. The same is true for chisels.
- Keep both ends of a chisel or punch properly ground and shaped. A chisel's cutting edge should be sharp and square. A starting punch or a pin punch should also be ground flat and square. A center punch should have a sharp point.
- After prolonged hammering, the top of a chisel or punch can become deformed and enlarged. This is called mushrooming. A mushroomed chisel or punch is dangerous! Grind off the mushroom and form a chamfer, as shown in **Figure 3-18.**
- When grinding a chisel or punch, grind slowly to avoid overheating the tool. Excessive heat will cause the tool to turn blue, lose its temper, and become soft.
- Make sure to wear eye protection when using or grinding a chisel or punch.

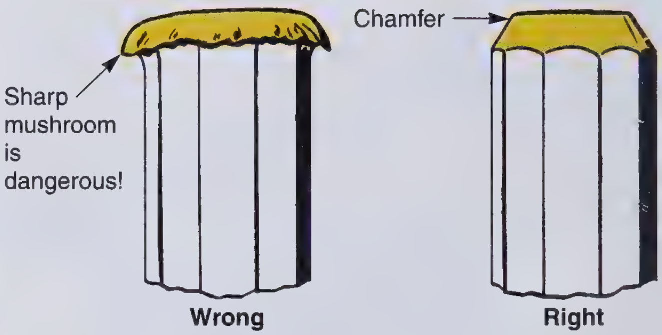

Figure 3-18. Always keep the top of a chisel or punch ground to a chamfer. A sharp, mushroomed end is dangerous. (Deere & Co.)

Files

Files remove burrs, nicks, and sharp edges and perform other smoothing operations. They are useful when only a small amount of material must be removed. The basic parts of a file are shown in **Figure 3-19.**

A file is classified by its length, shape, and cutting surface. Generally, a ***coarse file*** with large cutting edges should be used on soft materials, such as plastic, brass, and aluminum. A ***fine file*** with small cutting edges is

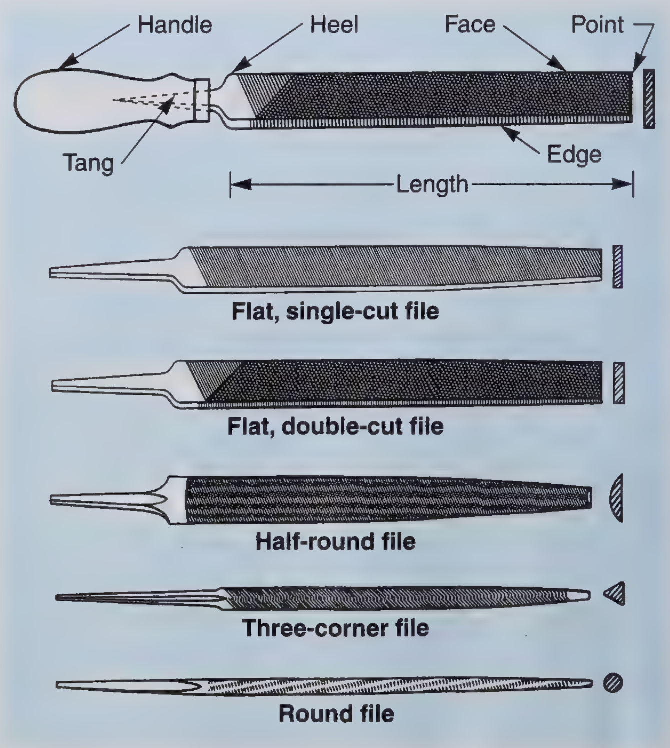

Figure 3-19. A file is used for smoothing metal. Note the different parts of a file and the different types of files available. (Starrett)

needed to produce a smoother surface and to cut harder materials, like cast iron or steel.

There are several file safety rules that should be remembered. These are:

- Never use a file without a handle securely attached. If the file's pointed tang is not covered by a handle, it can puncture your hand or wrist.
- To prevent undue file wear, apply pressure only on the forward stroke. Lift the file on the backstroke.
- When filing, place one hand on the handle and the other on the file tip. Hold the file firmly but *do not* press too hard.
- *Do not* file too rapidly. One file stroke every second is fast enough. Count to yourself: one thousand one, one thousand two, one thousand three, one thousand four, etc. This will time your strokes properly at about 50–60 strokes per minute.
- If a file becomes clogged, clean it with a file card or a stiff wire brush.
- Never hammer on or pry with a file. A file is very brittle and will break easily. Bits of the file can fly into your face or eyes.

Saws

A ***hacksaw*** is used to cut metal objects. Various blade lengths can be mounted in its adjustable frame. The blade teeth should point *away* from the handle, and the blade should be fastened tightly in the frame.

Select the appropriate blade for the job. As a rule of thumb, at least two saw teeth should contact the material being cut at any given time. If not, the teeth can catch and break.

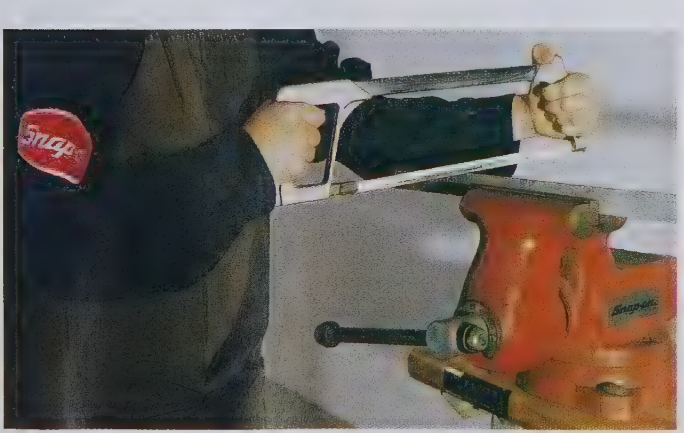

Figure 3-20. Hacksaws are used to cut metal. Hold the saw as shown and only push down on the forward stroke.

When cutting, place one hand on the hacksaw handle and the other on the end of the frame. Press down lightly on the forward stroke and release pressure on the backstroke. See **Figure 3-20.** As with a file, use 50–60 strokes per minute. If cuts are made faster than this, the blade will quickly overheat, soften, and become dull.

Holding Tools

There are several different types of tools used for holding objects in the automotive shop. These tools are covered in the next sections.

Vise

A ***vise*** is used to hold parts during cutting, drilling, hammering, and pressing operations. See **Figure 3-21.** It is mounted on a workbench. Avoid clamping a smooth, machined part in the uncovered jaws of a vise. If a machined surface is scarred, the part may be ruined.

Vise caps or wood blocks should be used to prevent damage when mounting precision or delicate parts in a vise. Vise caps are soft metal jaw covers. They will not only protect the part, but will provide a more secure grip on the part.

A few vise rules include:

- Never hammer on a vise handle to tighten or loosen the vise. Use the weight of your body.
- Keep the moving parts of the vise clean and oiled.
- Wear safety glasses when using a vise. Tremendous clamping force can be exerted and parts may break and fly out.

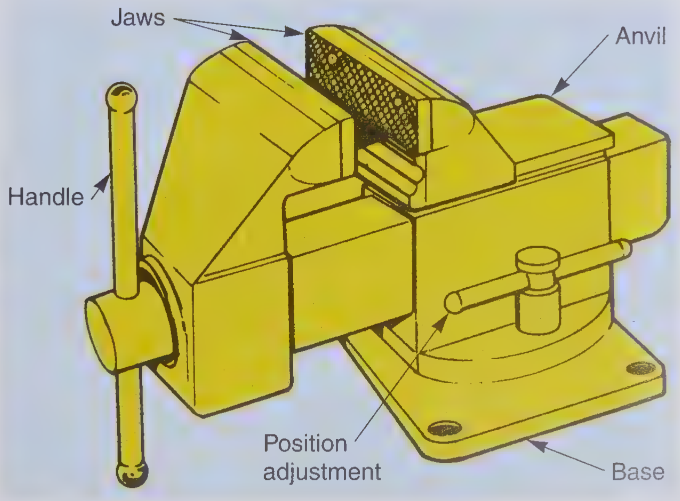

Figure 3-21. A vise mounts on the workbench. It holds parts securely. (Snap-on Tool Corp.)

- Be careful not to damage parts in the jaws of a vise.
- Use vise caps when a precision part is held in a vise. This will prevent part damage.

C-clamp

A ***C-clamp*** holds parts on a work surface when drilling, filing, cutting, welding, or doing other operations. Being portable, it can be taken to the job. Refer to **Figure 3-22.** C-clamps come in many different sizes.

Stands and Holding Fixtures

Stands and ***holding fixtures*** can be used to secure heavy or clumsy parts during repairs, **Figure 3-23.** Cylinder head stands, transmission fixtures, rear axle holding stands, and others will make your work safer and easier. Always use them when available.

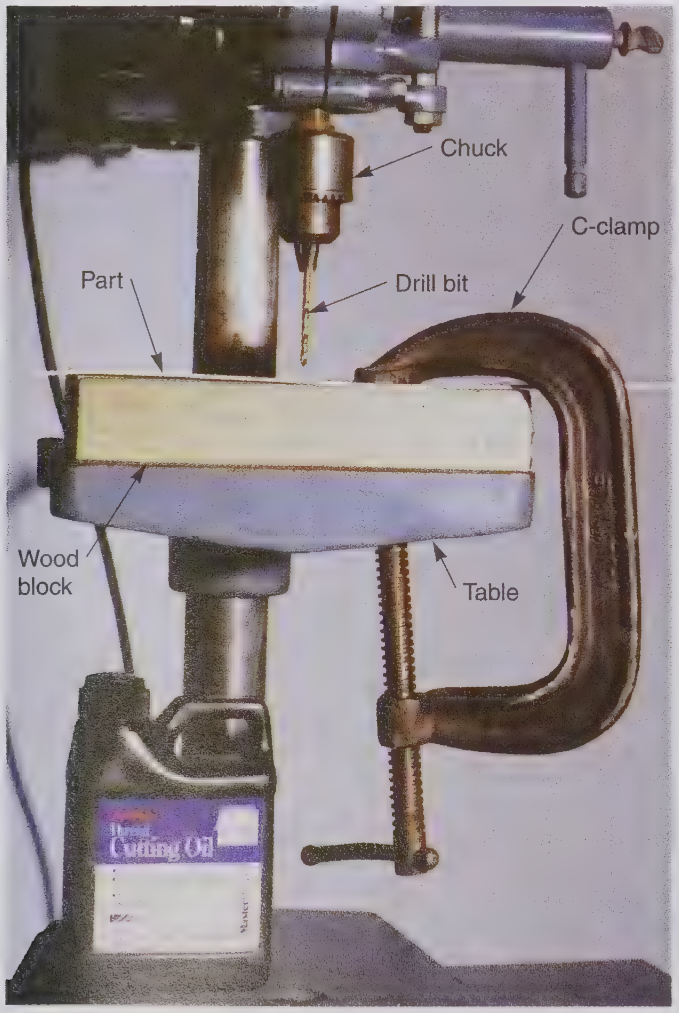

Figure 3-22. A C-clamp is a portable means of securing parts. It can also be used for light pressing operations.

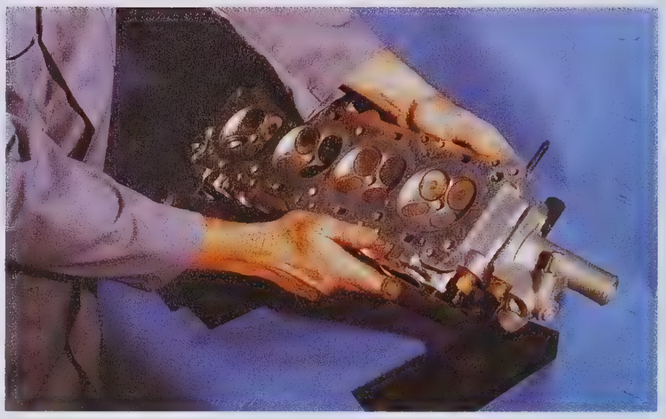

Figure 3-23. A cylinder head stand holds the head in position during valve and seat work. Other specialized stands are available for transmissions, differentials, and other parts.

Cleaning Tools

There is an old saying, "if you do the job right, you will spend most of your time cleaning parts." Dirt is a major enemy of a vehicle. One grain of sand can cause a major breakdown by clogging a passage or scarring a part. ***Cleaning tools,*** such as scrapers and brushes, help the technician remove carbon, rust, dirt, grease, old gaskets, and dried oil from parts.

Scrapers remove grease, gaskets, sludge, dried oil, and carbon on parts. They are used on flat surfaces. Never scrape toward your body. Keep your other hand out of the way. ***Brushes*** are used to remove light rust and dirt on parts. They are slow and should be used only when necessary.

Probe and Pickup Tools

Pickup and ***probing tools*** are needed when bolts, nuts, or other small parts are dropped and cannot be reached by hand. A ***magnetic pickup tool*** is a magnet hinged to the end of a rod. It can usually be shortened or lengthened and swiveled to reach into any area. If a ferrous (iron) metal part is dropped, it will be attracted and stick to the magnet, **Figure 3-24A.**

A ***finger pickup tool*** grasps nonmagnetic parts (aluminum, plastic, or rubber), which will *not* stick to a magnet, **Figure 3-24B.** A ***mirror probe*** allows you to look around corners or behind parts, **Figure 3-24C.** For example, a mirror probe will allow you to see an oil leak behind the engine.

Pry Bars

Pry bars are strong steel bars. They are helpful during numerous assembly, disassembly, and adjustment operations. For example, they are commonly used when

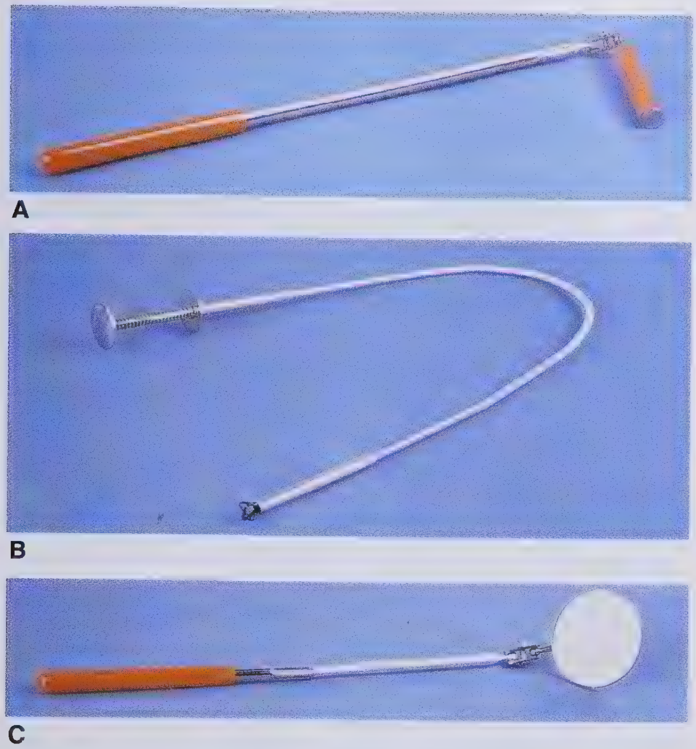

Figure 3-24. Different probe and pickup tools. A—Magnetic pickup tool. B—Finger pickup tool. C—Mirror probe.

adjusting the tension of engine belts. They are also used to align heavy parts. When prying, always be careful to *not* damage any part of the vehicle.

Workplace Skills

A properly designed tool acts as an extension of your body or mind. Tools are essential to the repair of any motor vehicle. For this reason, you should learn about new tools as they are developed. A good tool is a wise investment that will help you be a more productive, successful technician. To learn more about tools, you might want to log onto tool manufacturer websites, such as www.snapon.com.

Summary

- It is almost impossible to do even the simplest auto repair without using some type of tool.
- Professional auto technicians invest thousands of dollars in tools. A well-selected set of tools will speed up repairs, improve work quality, and increase profits.
- Purchase quality tools. Quality tools are lighter, stronger, easier to use, and more dependable than off-brand, bargain tools.
- Keep tools organized. There should be a place for every tool and every tool should be in its place.
- Use the right tool for the job. A good technician will know when, where, and why a particular tool will work better than another.
- A toolbox stores and protects a technician's tools when not in use.
- A 6-point wrench is the strongest wrench configuration.
- A socket is a cylinder-shaped, box-end tool for removing or installing bolts and nuts.
- Socket handles fit into the square opening in the top of the socket.
- A ratchet is the most commonly used and versatile socket handle. It can either loosen or tighten bolts.
- Extensions are used between a socket and its handle.
- Pliers are used to grip, cut, crimp, hold, and bend various parts.
- A hacksaw is the saw most frequently used by the technician.
- A vise is used to hold parts during cutting, drilling, hammering, and pressing operations.
- Cleaning tools, such as scrapers and brushes, help a technician remove carbon, rust, dirt, grease, old gaskets, and dried oil from parts.
- Pry bars are strong steel bars that are helpful during numerous assembly, disassembly, and adjustment operations.

Review Questions—Chapter 3

Please do not write in this text. Place your answers on a separate sheet of paper.

1. List and explain four general tool rules.
2. A bolt head is rusted and partially rounded off. Which wrench would work best for removing the bolt?
   (A) Open-end wrench.
   (B) 6-point box-end wrench.
   (C) 12-point box-end wrench.
   (D) None of the above.
3. What are the four socket drive sizes? Explain when each should be used.
4. _____ or _____ screwdrivers are useful in very tight places, such as inside a glove box.
5. Describe four rules to follow when using hammers.
6. What is the difference between a center punch, a starting punch, and an aligning punch?
7. A coarse file should be used on _____ materials. A fine file should be used on _____ materials.
8. When should you use vise caps?
9. List and explain four vise rules.
10. Which of the following tools should be used to remove old gasket material from a flat surface?
    (A) Hand scraper.
    (B) Chisel.
    (C) Probe.
    (D) Pry bar.

ASE-Type Questions

1. A bolt head is badly rusted and is difficult to loosen. Technician A says to use a pair of pliers to loosen the rusted bolt. Technician B recommends a six-point wrench or socket. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Which of the following is *not* a common socket drive size?
   (A) 1/4″
   (B) 3/8″
   (C) 5/8″
   (D) 1/2″
3. The most commonly used and versatile socket handle is the:
   (A) ratchet.
   (B) flex bar.
   (C) breaker bar.
   (D) speed handle.
4. A(n) _____ is a swivel that lets the socket wrench reach around obstructions.
   (A) extension
   (B) hand spinner
   (C) flexible driver
   (D) universal joint
5. When working with sockets, Technician A states that a socket's "point" is the size of the square opening for the handle. Technician B states the point of a socket is the box configuration for the bolt head. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Which type of screwdriver is especially good to use in tight spaces?
   (A) Torx.
   (B) Offset.
   (C) Phillips.
   (D) Clutch head.
7. Pliers are used on various parts to do each of these *except:*
   (A) cut.
   (B) grip.
   (C) bend.
   (D) screw.
8. Which type of pliers open extra wide to hold very large objects?
   (A) Rib joint.
   (B) Channel lock.
   (C) Water pump.
   (D) All the above.
9. The heaviest kind of hammer is:
   (A) lead.
   (B) brass.
   (C) sledge.
   (D) dead blow.
10. Which punch configuration is used to mark parts for reassembly or to start a drilled hole?
    (A) Center.
    (B) Aligning.
    (C) Tapered.
    (D) Diamond.

Activities—Chapter 3

1. Collect automotive catalogs and create a list of hand tools needed to equip an automotive shop. Provide an estimate of what it will cost to purchase the tools.
2. Discuss tool safety with your instructor. Prepare a list of safety regulations for your shop area.

4 Power Tools and Equipment

After studying this chapter, you will be able to:

- List the most commonly used power tools and equipment.
- Describe the uses for power tools and equipment.
- Explain the advantages of one type of tool over another.
- Explain safety rules that pertain to power tools and equipment.
- Correctly answer ASE certification test questions that require a knowledge of power tools and equipment.

To be a productive technician in today's automotive service facility, you must know when and how to use power tools and equipment. ***Power tools*** are tools driven by compressed air, electricity, or pressurized liquid. They make many repair operations easier and quicker. Large shop tools, such as floor jacks, parts cleaning tanks, and steam cleaners, are called ***shop equipment.***

This chapter discusses properly selecting and using common power tools and shop equipment. They can be very dangerous if misused. Always follow the operating instructions for the particular tool or piece of equipment before use. If in doubt, ask your instructor for a demonstration. Specialized power tools and equipment are covered in later chapters. Refer to the index to find more information on them as needed.

Compressed-Air System

The components of a ***compressed-air system*** include an air compressor, air lines, air hoses, and air tools. In addition, a pressure regulator, filter, and lubricator may be attached to the system. Air tools are driven by the compressed-air system. Air-powered tools can be found in nearly every service facility.

Air Compressor

An ***air compressor*** is the source of compressed air for an automotive service facility. Look at **Figure 4-1.** An air compressor normally has an electric motor that spins an air pump. The air pump forces air into a large, metal storage tank. The air compressor turns on and off automatically to maintain a preset pressure in the system. Metal air lines feed out from the tank to several locations in the shop. Technicians can then connect their flexible air hoses to the metal lines.

Warning!
Shop air pressure usually ranges from 100–150 psi (689–1034 kPa). This is enough pressure to kill or severely injure a person. Respect shop air pressure!

Air Hoses

Flexible, high-pressure ***air hoses*** are connected to the metal lines from the air compressor. These hoses allow the technician to take a source of air pressure to the vehicle being repaired. ***Quick-disconnect couplings*** are used to connect air hoses and air tools to the compressed air system without using a wrench. To join or separate a quick-disconnect coupling, pull back on the coupling's outer sleeve with finger pressure. With the sleeve pulled back, you can push the coupling together or pull it apart.

Other Components

A ***pressure regulator*** is used to set a specific pressure in the compressed-air system. This pressure is often called ***shop pressure.*** In most cases, shop pressure is between 100 and 150 pounds per square inch (psi). A filter may be connected to the system. The ***filter*** removes water from the compressed air. This increases the life of air tools. In addition, a lubricator may also be connected

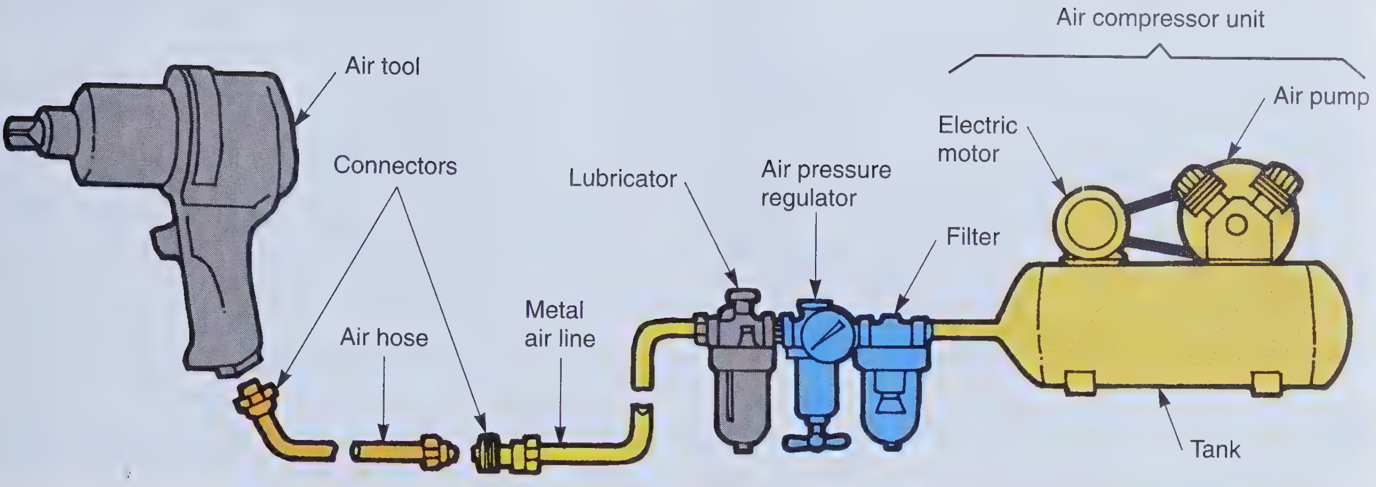

Figure 4-1. The basic parts of a typical compressed air system. The air compressor unit develops air pressure. The filter removes moisture. The regulator allows the technician to control system pressure. Metal lines and flexible hoses carry pressurized air to the tool. (Florida Dept. of Voc. Ed.)

to the system. The ***lubricator*** introduces oil into the airstream. This also increases the life of air tools.

Air Tools

Air tools use the energy of compressed air for operation. They are also called ***pneumatic tools.*** Air tools are labor-saving devices and well worth their cost. Always lubricate an air tool before and after use. While pressing the air tool's trigger, squirt a few drops of air tool oil into the tool's air inlet fitting Not only will the oil protect the internal parts of the tool during use, but it will also prevent the internal parts from rusting during storage.

Air Wrenches

Air wrenches, or ***impact wrenches,*** provide a very fast means of installing or removing threaded fasteners. Look at **Figure 4-2A.** An impact wrench uses compressed air to rotate a driving head. The driving head holds a special impact socket.

Impact wrenches come in 3/8″, 1/2″, and 3/4″ drive sizes. A 3/8″ drive impact is ideal for small fasteners, such as 1/4″–9/16″ bolts. A 1/2″ drive is for general purpose use with medium to large fasteners, such as 1/2″–1″ bolts. The 3/4″ drive impact is for extremely large fasteners. It is *not* commonly used in automotive service. A button or switch on the impact wrench controls the direction of rotation. In one position, the impact wrench tightens the fastener. With the switch in the other position, the wrench loosens the fastener.

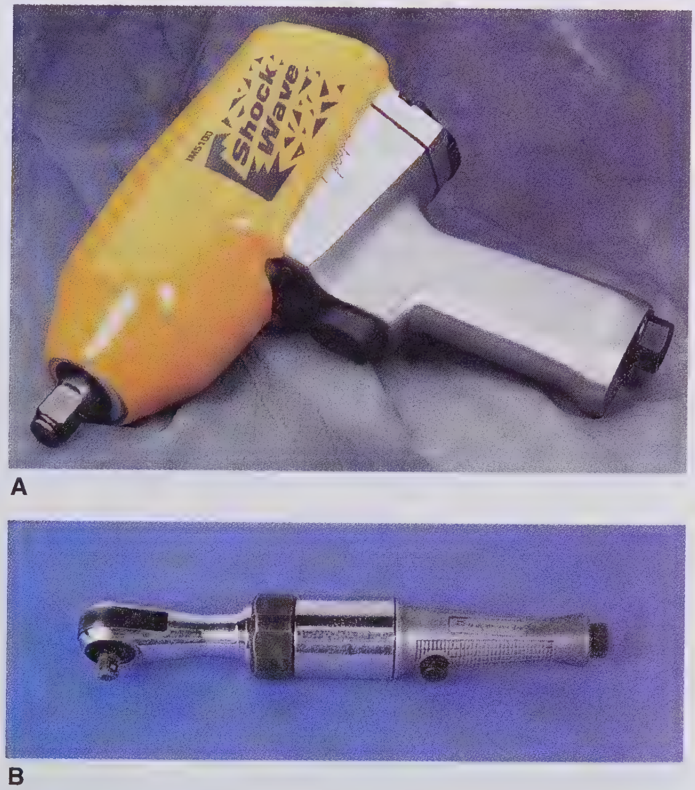

Figure 4-2. A—1/2″ drive impact wrench. B—3/8″ drive air ratchet. (Snap-on Tool Corp.)

Caution!
Until you become familiar with the operation of an air wrench, be careful not to overtighten bolts and nuts or leave them too loose. It is easy to strip or break fasteners with an air tool.

Air Ratchet

An *air ratchet* is a special impact wrench designed for working in limited space. Look at **Figure 4-2B.** For instance, an air ratchet is commonly used when removing water pumps. It will fit between the radiator and engine easily. It works in much the same way as a hand-tool ratchet. An air ratchet normally has a 3/8″ drive. However, it does not have very much turning power. Final tightening and initial loosening must be done with hand tools.

Impact Sockets and Extensions

Special *impact sockets* and *impact extensions* must be used with air wrenches. These are case hardened, thicker, and much stronger than conventional sockets and extensions. A conventional socket can be ruined or broken by the hammering blows of an impact wrench. Impact sockets and extensions are easily identified because they are flat black, not chrome.

Caution!
Know when and when not to use power tools. In most situations, power tools will speed up your work. However, there are many times when they should not be used. For example, never use an impact wrench in place of a torque wrench. An impact wrench will not torque critical fasteners to their correct specification. Problems and comebacks will result.

Air Hammer

An *air hammer,* or *air chisel,* is useful during various driving and cutting operations. Look at **Figure 4-3.** An air hammer is capable of producing about 1000–4000 impacts per minute. Several different cutting or hammering attachments are available. Be sure to select the correct one for the job.

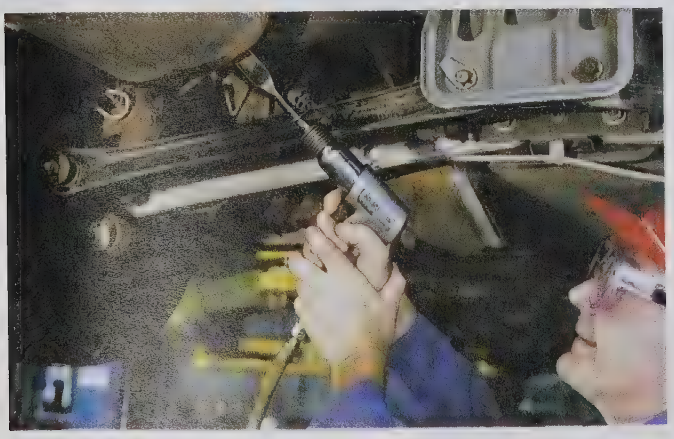

Figure 4-3. An air hammer is useful for tasks such as quickly cutting off a rusted exhaust system. *Always* wear safety glasses.

Warning!
Never turn an air hammer on unless the tool head is pressed tightly against the workpiece. Otherwise, the tool head can fly out of the hammer with great force, as if shot from a gun!

Blowgun

An air-powered ***blowgun*** is commonly used to dry and clean parts washed in solvent. It is also used to blow dust and loose dirt from parts before or during disassembly. See **Figure 4-4A.**

When using a blowgun, wear eye protection. Direct the blast of air away from yourself and others. Do not blow brake and clutch parts clean. The dust from these parts may contain asbestos. Asbestos is a cancer-causing substance. Another type of blowgun is a ***solvent gun,*** **Figure 4-4B.** It can be used to wash parts that will not fit into a cleaning tank.

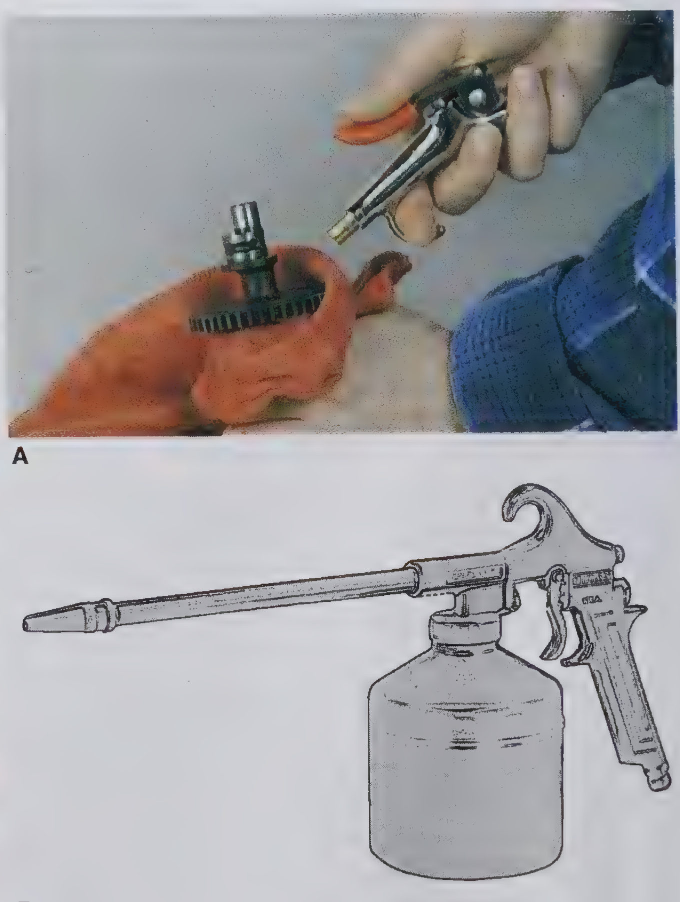

Figure 4-4. A—A blowgun is commonly used to blow parts clean and to dry parts after washing them in solvent. B—A solvent gun can be used to wash parts.

Air Drill

An ***air drill*** is excellent for many repairs because of its power output and speed adjustment capabilities. Its power and rotating speed can be set to match the job at hand. Look at **Figure 4-5**. With the right attachments, air drills can drill holes, grind, polish, and clean parts.

A ***rotary brush*** is used in an air or electric drill for rapid cleaning of parts, **Figure 4-6**. It can quickly remove old gasket material, carbon deposits, and rust with a minimum amount of effort.

An ***abrasive pad*** is another type of cleaning tool that can be used in an air or electric drill. It is used for removing old gasket material. It has the advantage of not scratching aluminum like a rotary brush can.

A ***rotary file,*** or ***stone,*** can be used in an air drill, electric drill, or air (die) grinder, **Figure 4-7.** It is handy for removing metal burrs and nicks. Make sure the stone is not turned too fast by the air tool. Normally, the maximum speed is printed on the file or stone container.

Warning!
Use a high-speed rotary brush in an air drill. A brush designed for an electric drill may fly apart. To be safe, always adjust an air drill to the slowest acceptable speed when using a rotary brush. Also, always wear eye protection.

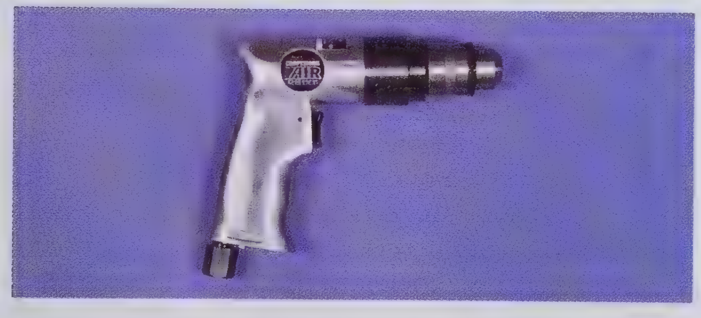

Figure 4-5. An air drill. The speed of the air drill can be adjusted. The air drill is capable of very high turning force.

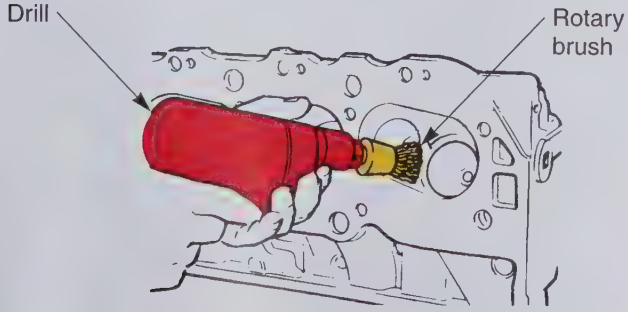

Figure 4-6. A rotary brush is commonly used in a drill for cleaning off carbon deposits or old gaskets. *Always* wear eye protection.

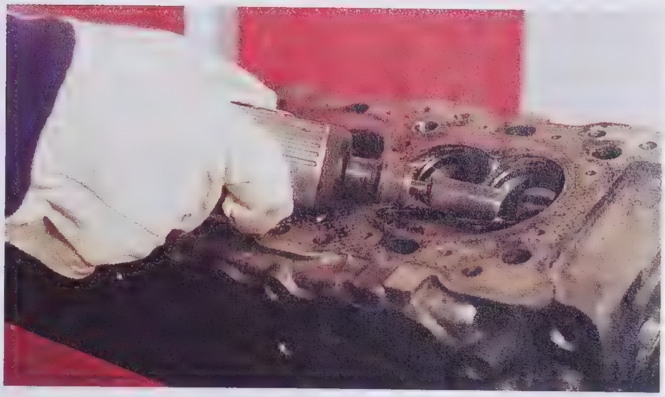

Figure 4-7. This die grinder is equipped with a high-speed stone. This tool is used for removing burrs and for other smoothing operations. Here, the technician is making minor repairs to a damaged cylinder head combustion chamber.

Electric Tools

There are many ***electric tools*** that can be useful to a technician. Some of these tools, such as a drill press or grinder, may be fixed to the floor or a bench. Other tools, such as a drill, are portable and can be taken to the job site.

Bench Grinder

A ***bench grinder*** can be used for grinding, cleaning, or polishing operations, **Figure 4-8**. A bench grinder usually has two wheels—a grinding wheel and a wire wheel. The hard, abrasive ***grinding wheel*** is used for sharpening and deburring. The soft ***wire wheel*** is used for cleaning and polishing. A few bench grinder rules to follow are:

- Always wear eye protection and keep your hands away from the wheel.
- Make sure the grinder shields are in place.
- Keep the tool rest adjusted close to the wheel. If the rest is *not* close to the wheel, the part being ground can catch in the grinder.
- Do *not* use a wire wheel to clean soft metal parts, such as aluminum pistons or brass bushings. The abrasive action of the wheel can remove metal or scuff the part and ruin it. Instead, use a solvent and a dull hand scraper on soft metal parts that could be damaged.

Drills

Drills are used to create holes in metal and plastic parts. Some drills are portable; others are mounted on a workbench or the floor. Drills use different-size bits to create the size of hole needed.

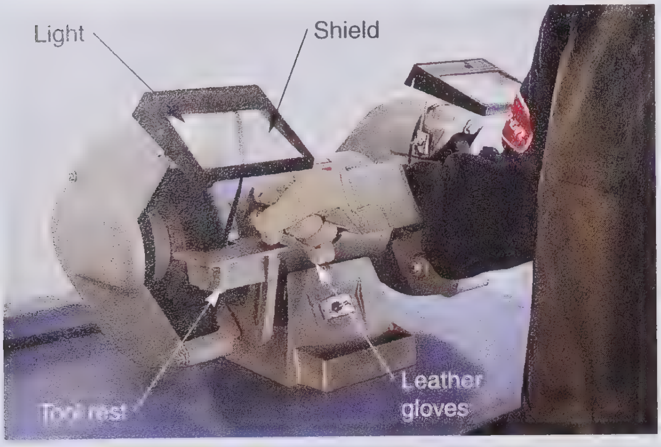

Figure 4-8. The grinding wheel on a bench grinder is used to sharpen tools. The wire wheel can be used to clean and polish small parts. *Always* keep shields, tool rests, and guards in place.

Bits

Drills use ***drill bits,*** or ***twist drills,*** to drill holes in metal and plastic parts, **Figure 4-9.** A drill bit is mounted in the drill ***chuck***. A special key, called a ***chuck key,*** is sometimes needed to tighten the drill bit in the chuck, **Figure 4-10.** Drill bits are commonly made of either carbon steel or high-speed steel. High-speed steel is better because of its resistance to heat. It will not lose its hardness when slightly overheated.

Portable Electric Drill

Portable electric drills are hand-held drills. They come in different sizes. The size of a drill is an indication of the capacity of its chuck. Commonly used sizes are 1/4″, 3/8″, and 1/2″, **Figure 4-11.** Portable electric drills work fine on most small drilling operations.

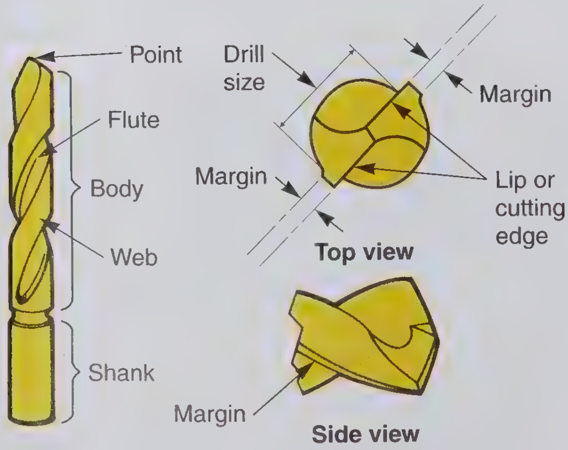

Figure 4-9. The basic parts of a drill bit. (Florida Dept. of Voc. Ed.)

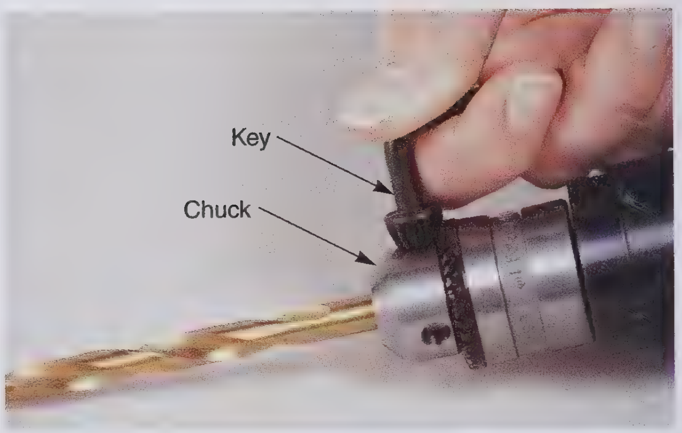

Figure 4-10. A key is used to tighten a bit in the chuck.

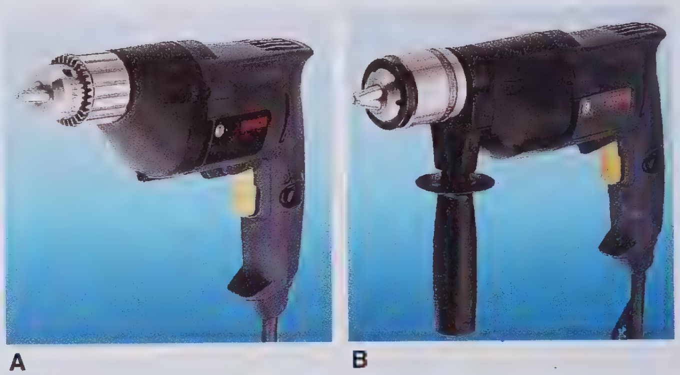

Figure 4-11. Portable electric drills. A—3/8″ drill. B—1/2″ drill. (Robert Bosch)

Drill Press

A ***drill press*** is a large, floor- or bench-mounted drill needed for drilling large holes, deep holes, or a great number of holes in several parts, **Figure 4-12.** The drill press handle allows the bit to be pressed into the work with increased force. Also, very large bits can be used. A few drill press rules to follow include:

- Remove the key from the chuck before turning on the drill press.
- Secure the part to be drilled with C-clamps or other holding fixtures.
- Use a center punch to indent the part and start the hole.
- To prevent injury, release drilling pressure right before the bit breaks through the bottom of the part. A drill bit tends to catch when breaking through. This can cause the drill or part to rotate dangerously.
- Oil the bit as needed.

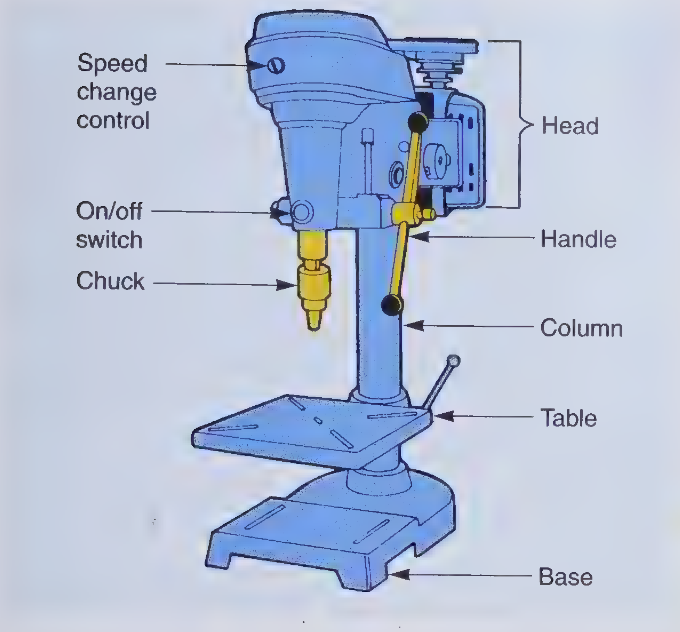

Figure 4-12. The parts of a drill press. A drill press is for drilling deep or large holes when a part will fit on the table. (Florida Dept. of Voc. Ed.)

Hydraulic Tools

Hydraulic tools are powered by pressurized liquid. The hydraulic tools typically used in the automotive shop include jacks, cranes, and presses. These tools are discussed in the next sections.

Floor Jack

A ***floor jack*** is used to raise either the front, sides, or rear of a vehicle. Look at **Figure 4-13.** To avoid vehicle damage, place the jack saddle under a solid part of the car such as the frame, suspension arm, or axle housing. If the saddle is not properly located, it is very easy to smash the oil pan, muffler, floor pan, or another part of the vehicle. To raise the vehicle, turn the jack handle or knob clockwise and pump the handle. To lower the vehicle, turn the handle or knob counterclockwise slowly to release the pressure-relief valve.

When raising the front of a vehicle, place the transmission in neutral and release the parking brake. This lets the vehicle roll, preventing it from pulling off the jack. After raising, secure the vehicle on jack stands. Place an automatic transmission in park and a manual transmission in gear. Apply the emergency brake and block the wheels. It is then safe to work under the vehicle.

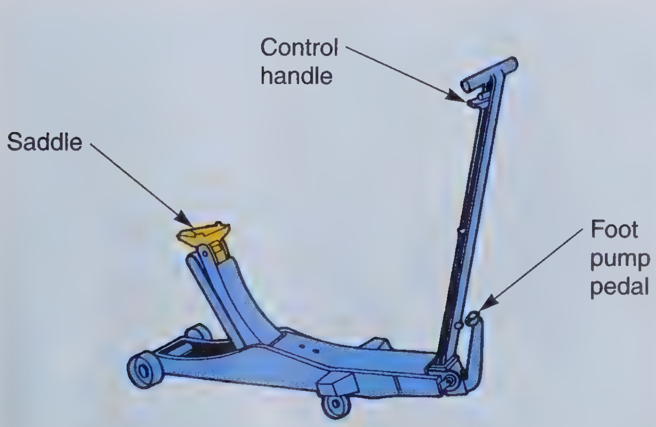

Figure 4-13. A floor jack is for raising the car only.

Caution!

Most floor jack handles tend to stick when the pressure-relief valve is released. This makes it easy for you to lower the vehicle too quickly. When releasing the valve, turn it very slowly. This will prevent the car or truck from slamming to the ground violently!

Transmission Jack

Transmission jacks are designed to hold transmissions and transaxles during removal or installation. One type is similar to a floor jack. However, the saddle is enlarged to fit the bottom of a transmission. Another type of transmission jack is designed to be used when the vehicle is raised on a lift, **Figure 4-14.** It has a long post that can reach high into the air to support the transmission.

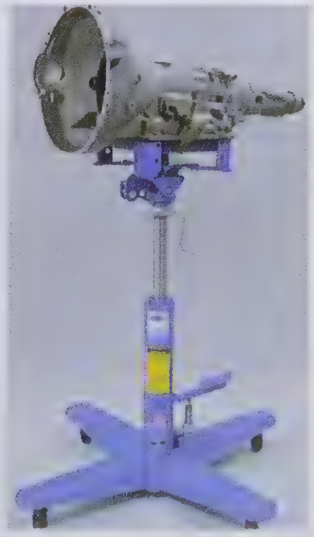

Figure 4-14. A transmission jack is designed for holding transmissions during removal, transporting, and installation. This foot-operated, hydraulic stand can be extended to a height of 72″. (OTC Div. of SPX Corp.)

Engine Crane

A portable ***engine crane*** is used to remove and install heavy engine assemblies, **Figure 4-15.** It has a hydraulic hand jack for raising engines and a pressure-release valve for lowering engines. The engine crane is also handy for lifting intake manifolds, cylinder heads, engine blocks, transmissions, transaxles, and other heavy parts.

Hydraulic Press

A ***hydraulic press*** is used to install or remove gears, pulleys, bearings, seals, and other parts requiring a high pushing force. One is shown in **Figure 4-16.** A hydraulic ram extends as the pump handle is worked. The ram presses the parts against a table.

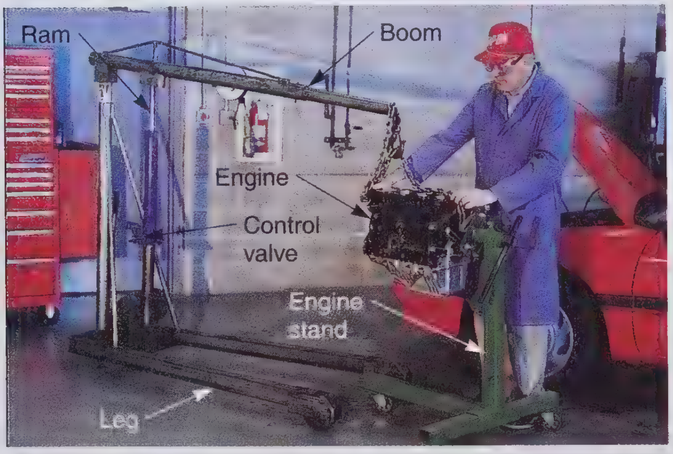

Figure 4-15. A hydraulic engine crane can be used to lift heavy objects, such as engines, transmissions, transaxles, and rear axle assemblies. This technician has used a crane to mount an engine on a stand.

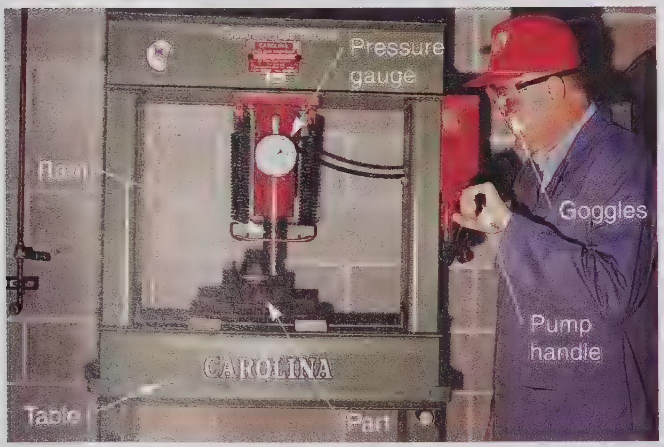

Figure 4-16. A hydraulic press is needed for numerous pressing operations. It is commonly used to remove and install bearings, bushings, seals, and other pressed-on parts.

Warning!
A hydraulic press can literally exert tons of force. Wear eye protection and use recommended procedures. Parts can break and fly out with deadly force!

Shop Equipment

In addition to pneumatic, hydraulic, and electric tools, there are various pieces of shop equipment that a technician may find useful. These include tire changers, stands, cleaners, welders, lights, and creepers. These are all discussed in the following sections.

Arbor Press

An ***arbor press*** works like a hydraulic press. However, it is all mechanical. Hydraulic pressure is not used; therefore, the operating pressure is much lower. An arbor press is suited for smaller jobs.

Tire Changer

A ***tire changer*** is used to remove and replace tires on wheels. It is a common piece of shop equipment. Some tire changers are pneumatic; others are hand operated. Do not attempt to operate a tire changer without proper supervision. Follow the directions provided with the changer.

Jack Stands

Jack stands support a vehicle during repairs. After raising the vehicle with a jack, place stands under the vehicle, **Figure 4-17.** Be sure the stands are placed in secure positions. For example, place jack stands under the frame, axle housing, or suspension arm.

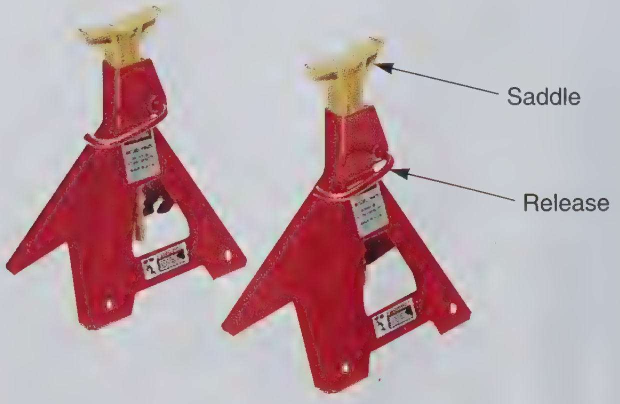

Figure 4-17. Jack stands are needed to safely support the weight of a vehicle.

Warning!
It is *not safe* to work under a vehicle held up by only a jack. Secure the vehicle on jack stands before placing any part of your body under the vehicle. Even a small car can weigh well over a ton. The next chapter details the safe use of lifts, jacks, and jack stands.

Engine Stand

An ***engine stand*** is used to hold an engine assembly once it is removed from the vehicle for rebuilding or repair. The engine cylinder block bolts to the stand just as it would to the transmission or transaxle. The engine can usually be rotated and held in different positions on the stand, making it easy to work on different parts.

Cold Solvent Tank

A ***cold solvent tank*** contains a pump, reservoir, and solvent, and it is used to remove grease and oil from parts, **Figure 4-18.** After removing all old gaskets and scraping off excess grease, you can scrub the parts clean in the solvent. A blow gun is then normally used to dry the solvent.

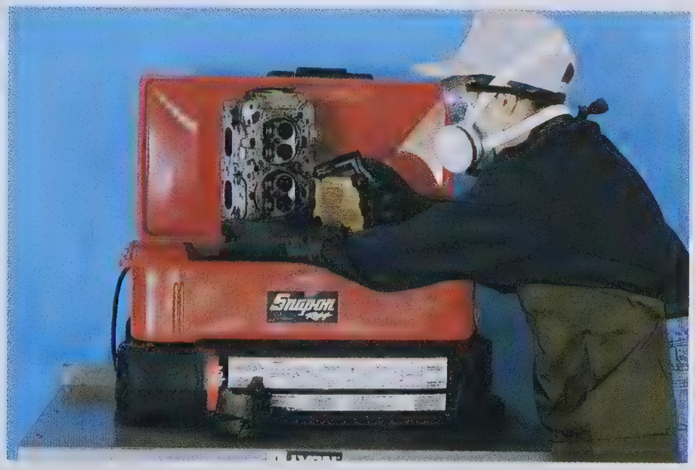

Figure 4-18. A cold-solvent tank is used to remove oil and light grease from parts. The unit sprays filtered solvent onto parts. Rub the parts with a brush for rapid cleaning.

Steam Cleaner and High-Pressure Washer

A ***steam cleaner*** or ***high-pressure washer*** is used to remove heavy deposits of dirt, grease, and oil from the outside of large assemblies, such as engines, transmissions, and transaxles. Look at **Figure 4-19.** To help keep the environment clean, wire brush the item to be cleaned and collect oil-soaked dirt before steaming or washing. Then, dispose of the oil-soaked material properly.

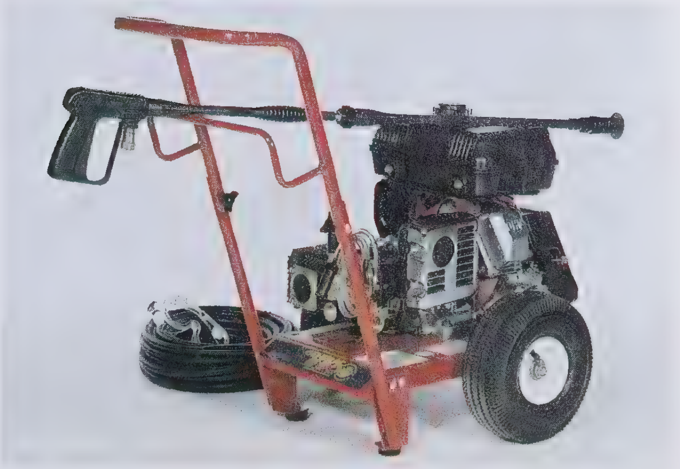

Figure 4-19. A high-pressure washer will remove greasy buildup from the outside of assemblies before teardown.

Warning!
A steam cleaner operates at high pressures and temperatures. Follow the manufacturer's safety rules and specific operating instructions.

Oxyacetylene Torch

An ***oxyacetylene torch*** can be used to heat, cut, weld, or braze metal parts, **Figure 4-20.** The oxyacetylene setup consists of an oxygen tank, an acetylene tank, pressure regulators, hoses, and a hand-held oxyacetylene torch. Tremendous heat is produced by the burning acetylene gas and oxygen. The rapid cutting action of this torch is extremely beneficial. For example, an oxyacetylene torch is often used to remove old, rusted exhaust systems.

Welder

A ***welder*** uses high electric current to create a hot electric spark, or arc, to melt and fuse metal parts together, **Figure 4-20.** Be sure to complete proper training before attempting to weld. Using a welder improperly can result in personal injury or damage to parts.

Warning!
Whenever working with a torch or welder, there is always a chance of fire. Always observe standard safety practices.

Soldering Gun

A ***soldering gun*** or ***soldering iron*** is used to join wires during electrical repairs, **Figure 4-21.** An electric

current heats the tip of the gun. The hot gun tip is used to heat the wires. Solder is then applied to the hot wires and it melts. ***Solder*** is a lead-tin alloy. When the solder cools, it hardens into a strong, solid connection.

Battery Charger

A ***battery charger*** is used to re-energize a "dead," or discharged, battery. It forces current back into the battery to recharge the plates and battery acid. The red charger lead connects to the positive (+) battery terminal. The black charger lead connects to the negative (–) battery terminal.

B
Power cord

Figure 4-21. Soldering irons and guns produce enough heat to melt solder for joining wires and small metal terminals. A—Soldering iron. B—Soldering gun. (Florida Dept. of Voc. Ed.)

Warning!
The gases around the top of a battery can explode. Always connect the battery charger leads to the battery *before* turning on the charger. This prevents sparks, which could ignite the battery gases.

Droplight

A ***droplight*** provides a portable source of light. The light can be taken to the repair area under the vehicle or in the engine compartment. Several types of droplights are shown in **Figure 4-22.**

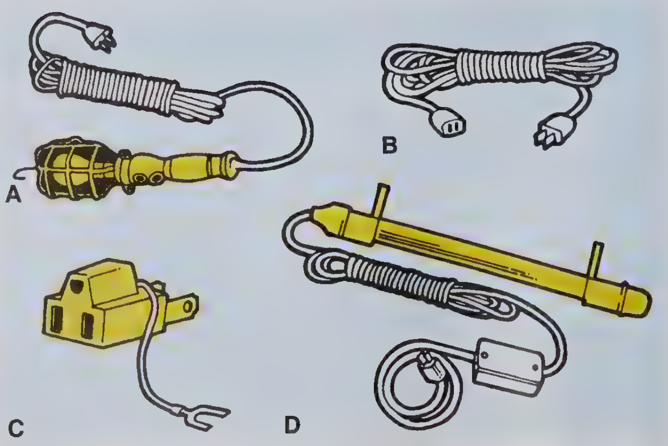

Figure 4-22. A—Droplight. B—Drop or extension cord. C—Three-prong adapter with ground terminal and ground wire for safety. D—Fluorescent droplight. (Florida Dept. of Voc. Ed.)

Pullers

Pullers are used to remove seals, gears, pulleys, steering wheels, axles, and other pressed-on parts. A few puller types are pictured in **Figure 4-23.** Special pulling operations are covered in later chapters.

Warning!
Pullers can exert tons of force. They must be used properly to prevent personal injury or part damage. Always wear eye protection!

Jumper Cables

Jumper cables are used to start a vehicle that has a dead battery. The cables are connected between the dead battery and another battery. The second battery is often in a running vehicle. Once the cables are connected, the car with the dead battery can be started. See **Figure 4-24.**

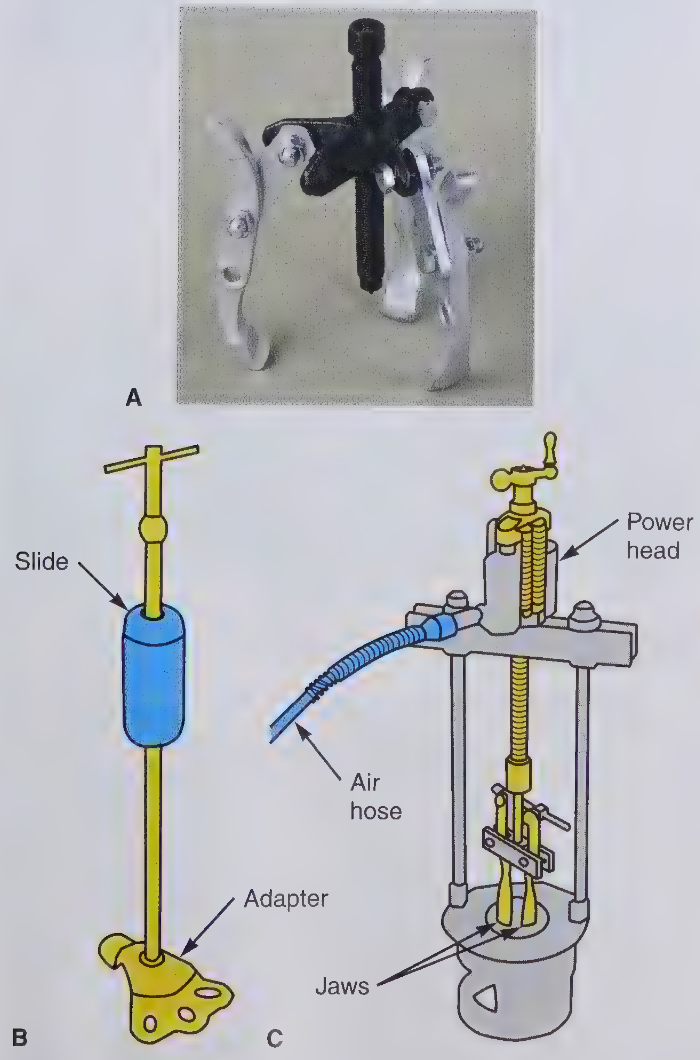

Figure 4-23. A—Three-way puller. B—Slide hammer puller. C—Power puller.

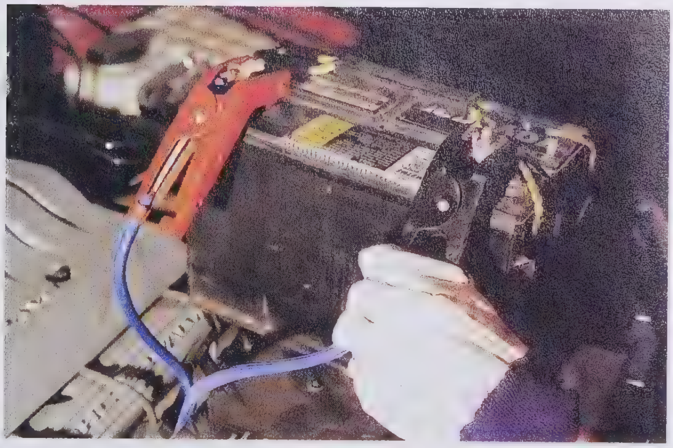

Figure 4-24. Jumper cables are for emergency starting. Connect the red lead to the positive terminal of both batteries. Black is for negative and ground. Never connect the terminals backwards or the batteries may explode.

When connecting jumper cables, connect positive to positive and negative to negative. Also, keep sparks away from the dead battery.

There is a specific sequence that should be followed when connecting the cables.

1. Connect the red jumper to the positive terminal on the dead battery.
2. Connect the red jumper to the positive terminal on the good battery.
3. Connect the black jumper to the negative terminal of the good battery or to a good ground on the vehicle with the good battery.
4. Connect the black jumper to a ground on the vehicle with the dead battery so sparks will not occur near the battery.

Warning!
As soon as the car starts, remove the black jumper from ground. Then carefully remove the remaining jumpers in reverse order.

Creepers

A ***creeper*** is useful when working under a car supported on jack stands, **Figure 4-25A.** It lets the technician easily roll under vehicles without getting dirty. A ***stool creeper*** allows the technician to sit while working on parts that are near the ground. See **Figure 4-25B.** For example, a stool creeper is often used during brake system repairs. The brake parts and tools can be placed on the creeper. The service technician can sit and still be at eye level with the brake assembly.

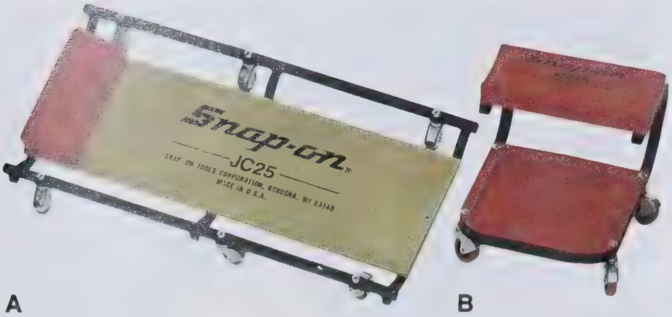

Figure 4-25. A—A creeper is for working under a vehicle. B—The stool creeper is commonly used during brake and suspension repairs. You can sit on the stool and store tools on the bottom. (Snap-on Tool Corp.)

Roll-Around Cart

A large ***roll-around cart*** or table is handy for taking a number of tools to the job. One is pictured in **Figure 4-26.** A technician can quickly place all needed tools in the cart and take them to the vehicle. The cart places the tools within hand's reach. This saves time and effort before, during, and after the job.

Covers

Fender covers are placed over fenders, upper grille, or other body sections to prevent vehicle damage. They protect the paint or finish from nicks, scratches, and grease. See **Figure 4-27A.** Never lay tools on a painted surface. Costly scratches may result.

Seat covers are placed over seats to protect them from dirt, oil, and grease that might be on your work clothes. These covers should be used while driving the vehicle or while working in the passenger compartment. Look at **Figure 4-27B.**

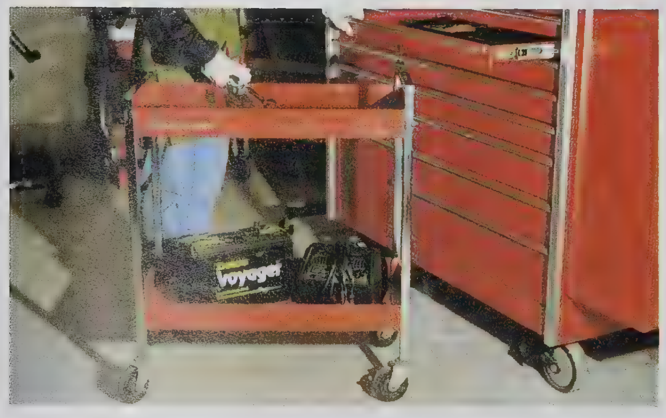

Figure 4-26. A roll-around cart allows you to take many tools to the vehicle. This saves several trips to the toolbox. It also saves time during cleanup at the end of the day. (Snap-on Tool Corp.)

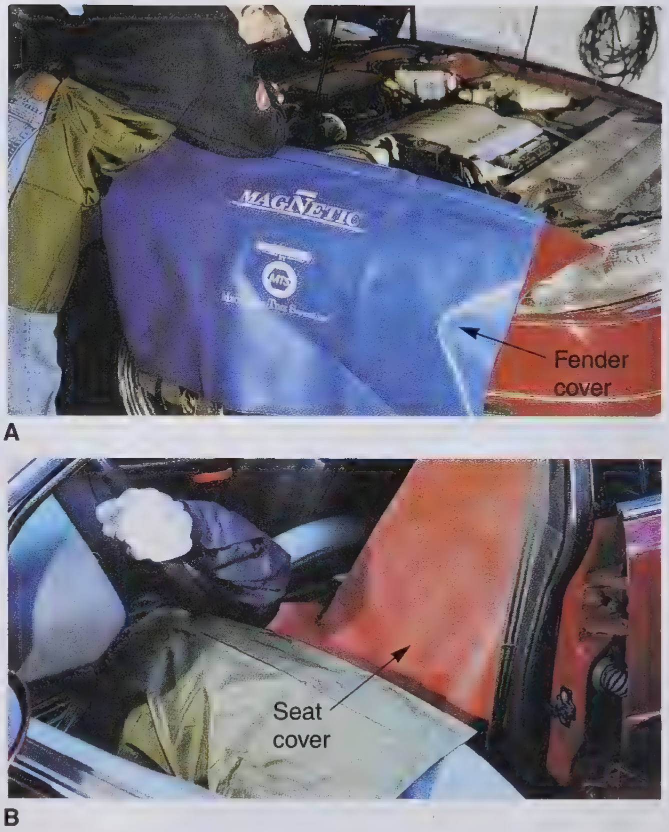

Figure 4-27. Always take good care of your customer's vehicle. A—Fender covers protect the paint from nicks and dents. B—Seat cover protects the upholstery from dirty work clothes.

Workplace Skills

Social skills are the techniques you use to conduct yourself in such a way that your customers and fellow employees like and respect you. Many times, you will need the help of another technician to complete a difficult task. If your co-workers dislike you, you may have trouble finding help when you need it.

Summary

- Power tools use electricity, compressed air, or hydraulic pressure (liquid confined under pressure). Large shop tools, such as floor jacks, parts cleaning tanks, and steam cleaners, are classified as shop equipment.
- An air compressor is the source of compressed (pressurized) air for the auto shop.
- High-pressure air hoses are connected to the metal lines from the air compressor.
- Air tools, also called pneumatic tools, use air pressure for operation. They are labor-saving tools and are well worth their cost.

- Air wrenches, or impact wrenches, provide a very fast means of installing or removing threaded fasteners.
- Special impact sockets and impact extensions must be used with air wrenches.
- A blowgun is commonly used to dry and clean parts washed in solvent.
- An air drill is excellent for many repairs because of its power output and speed adjustment capabilities.
- A bench grinder can be used for grinding, cleaning, or polishing operations. The hard grinding wheel is used for sharpening or deburring. The soft wire wheel is for cleaning and polishing.
- Drill bits, or twist drills, are used to drill holes in metal and plastic parts.
- A drill bit is mounted in and rotated by a drill. A special key is sometimes needed to tighten the drill bit in the drill chuck.
- A floor jack is used to raise either the front, sides, or rear of a vehicle.
- A tire changer is a common piece of shop equipment used to remove and replace tires on wheels.
- Jack stands support a vehicle during repair. After raising a vehicle with a jack, place stands under the vehicle.
- A portable engine crane is used to remove and install engines.
- An engine stand is used to hold an engine while it is overhauled (rebuilt) or repaired.
- A cold solvent tank can be used to remove grease and oil from parts.
- An oxyacetylene torch outfit can be used to heat, cut, weld, or braze metal parts.
- A welder is used to melt and fuse metal parts together.
- A soldering gun or iron is used to solder wires.
- A battery charger is used to recharge a discharged car battery.
- A droplight provides a portable source of light.
- Pullers are needed to remove seals, gears, pulleys, steering wheels, axles, and other pressed-on parts.
- Jumper cables are used to start engines that have a dead (discharged) battery.
- Fender covers are placed over the fenders, the upper grille, or other body sections to protect them.

Review Questions—Chapter 4

Please do not write in this text. Place your answers on a separate sheet of paper.

1. Power tools use _____, _____ _____, or _____ _____ as sources of energy.
2. Which of the following is *not* a commonly used air tool?
   (A) Impact wrench.
   (B) Air ratchet.
   (C) Air chisel.
   (D) Air saw.
3. A(n) _____ is used to blow dirt off parts and to dry parts after cleaning.
4. A rotary file is frequently used to remove _____.
   (A) old gasket materials
   (B) carbon deposits
   (C) metal burrs and nicks
   (D) None of the above.
5. List four important rules for a bench grinder.
6. List five important rules for a drill press.

7. _____ are used to support a vehicle while working under it.
   (A) Floor jacks.
   (B) Jack stands.
   (C) Transmission jacks.
   (D) Bumper jacks.
8. Explain the use of a solvent tank.
9. What are wheel pullers for?
10. A 1/2″ drive impact wrench is used for fasteners with head sizes between 1/2″ to 1″. Which of the following sockets can be used by this particular tool?
    (A) 5/8″ chrome plated socket.
    (B) 9/16″ flat black socket.
    (C) 7/16″ flat black socket.
    (D) None of the above.

ASE-Type Questions

1. Power tools are tools that use:
   (A) electricity.
   (B) hydraulics.
   (C) compressed air.
   (D) All the above.
2. Technician A says that shop air pressure is usually around 100 to 150 psi. Technician B says shop air pressure is much higher, around 300 psi. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither nor B.
3. Which of the following is *not* a common impact wrench drive size?
   (A) 1/4″.
   (B) 3/8″.
   (C) 1/2″.
   (D) 3/4″.
4. Technician A says to use a 1/4″ drive on sockets from 1/4″ to 9/16″. Technician B says to use a 3/8″ drive on these socket sizes. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. Special impact sockets and extensions are easily identified because they are:
   (A) chrome.
   (B) aluminum.
   (C) flat black.
   (D) hard rubber.
6. Each of the following can be used to clean parts *except:*
   (A) air drill.
   (B) blowgun.
   (C) air ratchet.
   (D) bench grinder.
7. Which of the following is *not* a rule to follow when using a bench grinder?
   (A) Wear eye protection.
   (B) Make sure shields are in place.
   (C) Use the wire wheel to clean soft metal parts.
   (D) Keep the tool rest adjusted close to the stone and brush.
8. When using a drill press, Technician A believes drilling pressure should not be released until the bit breaks completely through the bottom of the part. Technician B believes pressure release should occur just before the bit breaks through. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. After using a floor jack to raise the front of a car:
   (A) place the car in park.
   (B) block the car's wheels.
   (C) secure the car on jack stands.
   (D) All of the above.
10. The _____ press performs the same function as a hydraulic press, but at lower pressures.
    (A) arbor
    (B) steam
    (C) rotary
    (D) ratchet

Activities for Chapter 4

1. Using an automotive tool catalog, develop a list of power tools needed to equip your school's automotive repair shop. Find prices and add up the cost.
2. Research safety literature on power equipment used in an automotive repair facility.
   (A) Develop a bibliography of resources for safe use of power equipment.
   (B) Develop a list of safety rules for their use.

5

The Auto Shop and Safety

After studying this chapter, you will be able to:

- Describe the typical layout and sections of an auto shop.
- List the types of accidents that can occur in an auto shop.
- Explain how to prevent auto shop accidents.
- Describe general safety rules for the auto shop.

An auto shop can be a safe and enjoyable place to work. Most shops are clean, well lighted, and relatively safe, **Figure 5-1.** However, if basic safety rules are *not* followed, an auto shop can be very dangerous. In this chapter, the layout of a typical automotive service facility will be discussed and the most important safety rules will be emphasized.

Auto Shop Layout

There are several different areas in an auto shop. You must know their names and the basic rules that apply to each. It is important that you learn your shop layout and organization to improve work efficiency and safety. The auto shop includes the following work areas:

- Repair area (includes the shop stall, lift, alignment rack, and outside work area).
- Toolroom.
- Classroom.
- Locker room (dressing room).

Figure 5-1. A well-maintained automotive shop can be an enjoyable place to work. Always do your part to keep the shop clean and well organized.

Repair Area

The ***repair area*** includes any location in the shop where repair operations are performed. It normally includes every area *except* the classroom, locker room, and toolroom.

Shop Stall

A ***shop stall*** is a small work area where a car can be parked for repairs. Sometimes, each stall is numbered and marked off with lines painted on the floor.

Lift

The ***lift*** is used to raise a vehicle into the air. Refer to **Figure 5-2.** It is handy for working under the car

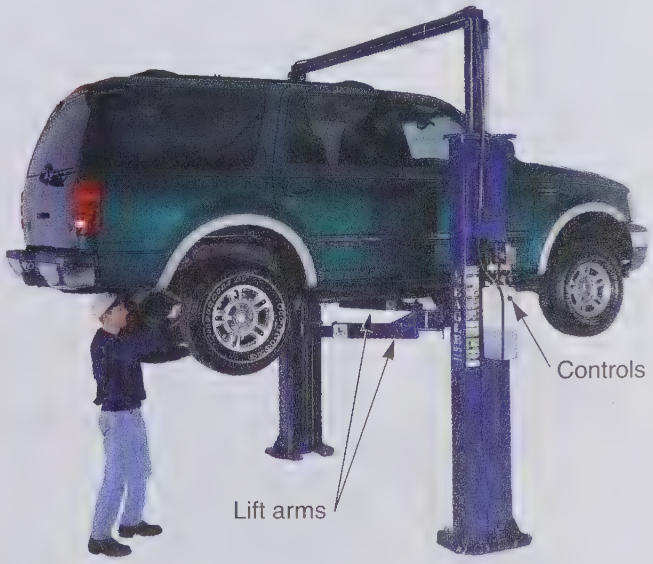

Figure 5-2. A lift is handy for repairs on parts located under the vehicle. It is commonly used when changing oil, greasing the chassis, and repairing the exhaust system. (Eagle Equipment)

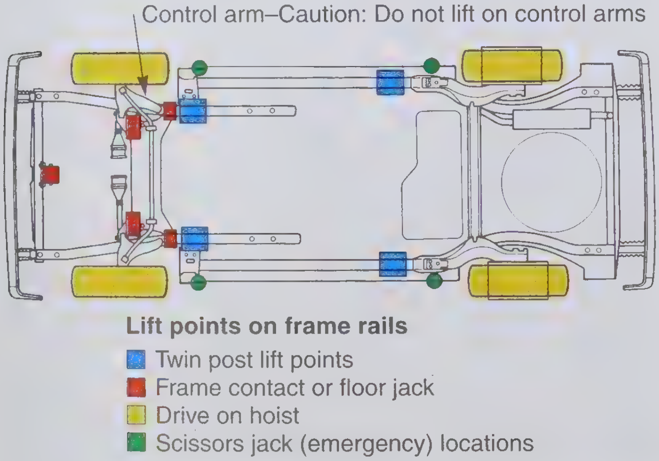
(draining oil, greasing front end parts, or repairing exhaust system).

Remember these ***lift safety rules:***

- Ask your instructor for a demonstration and get permission before using the lift.
- Center the vehicle on the lift as described in a service manual, **Figure 5-3.** Raise vehicle slowly.
- Check ceiling clearance before raising trucks and campers. Make sure the vehicle roof does not hit overhead pipes, lights, or the ceiling.
- Make sure the lift's safety catch is engaged. Do not walk under the lift without the catch locked into position, **Figure 5-4.**

Alignment Rack

The ***alignment rack,*** or ***front end rack,*** is another specialized stall used when working on a car's steering and suspension systems. One is shown in **Figure 5-5.** It may contain a special tool board and equipment used when replacing worn suspension and steering parts or adjusting wheel alignment.



Control arm–Caution: Do not lift on control arms
Lift points on frame rails
🟦 Twin post lift points
🟥 Frame contact or floor jack
🟨 Drive on hoist
🟩 Scissors jack (emergency) locations

Figure 5-3. Follow the service manual instructions when raising a car on a lift. Note the specific lifting instructions and lift points for this vehicle. (DaimlerChrysler)

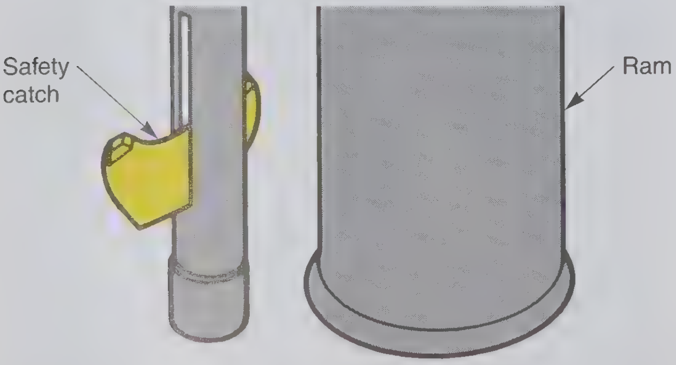


Figure 5-4. Most lifts have a safety catch. It must be engaged before working under the vehicle. (Ford)

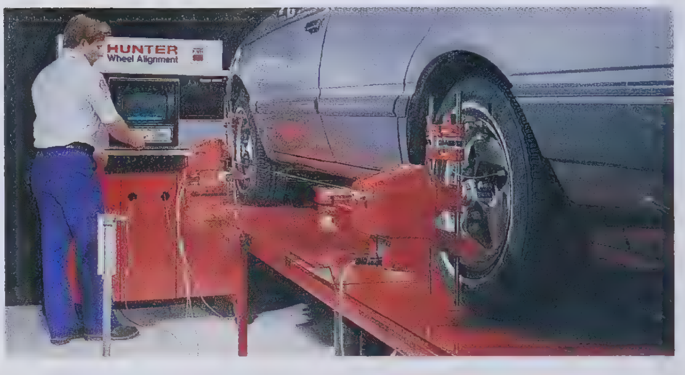

Figure 5-5. An alignment rack is used in most shops. It is often needed when servicing steering and suspension systems. (Hunter)

When using an alignment rack, the car should be pulled onto the rack slowly and carefully. Someone should *guide* the driver and help keep the tires centered on the rack. As with other complicated and potentially dangerous equipment, obtain a full demonstration before using the alignment rack.

Outside Work Area

Some auto shop facilities have an ***outside work area*** adjacent to the garage overhead doors. In good weather, this area can be used for auto repairs.

Always raise the shop doors all the way and pull cars through the doors very slowly. Check the height of trucks and campers to make sure they will clear (top of vehicle will not hit doors).

Toolroom

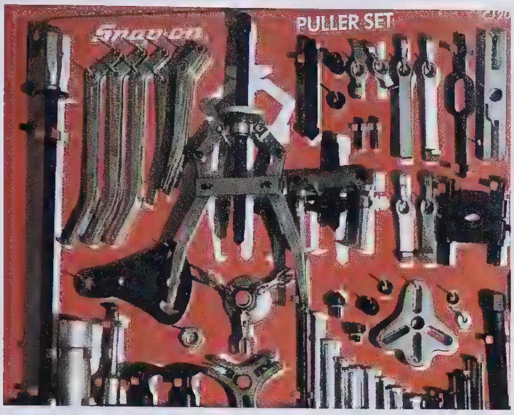
The ***toolroom*** is used to store shop tools, small equipment, and supplies (nuts, bolts, oil, etc.). It is normally located adjacent to (next to) the repair area or classroom.

When working in the toolroom, you will be responsible for keeping track of shop tools. Every tool checked out of the toolroom must be recorded and called in before the end of the class period.

Normally, the tools hang on the walls of the toolroom for easy access. Each tool may have a painted silhouette, which indicates where it should be kept, **Figure 5-6.** Your instructor will detail specific toolroom policies and procedures.

Classroom

The ***classroom*** is used for seminars, demonstrations, and other technician training activities. It is often located adjacent to the repair area.



Snap-on
PULLER SET

Figure 5-6. Keep all shop tools clean and organized. Make sure you return every tool to its correct location. (Snap-on Tools)

Locker Room

The ***locker room*** or ***dressing room*** provides an area for changing into your work clothes. It is usually located adjacent to the main shop.

Shop Safety

Every year, thousands of technicians are accidentally injured or killed on the job. Most of these accidents resulted from a broken safety rule. The injured persons learned to respect safety rules the hard way–by experiencing a painful injury. You must learn to respect safety rules the easy way–by studying and following the safety rules given in this book.

Note!
Specific safety rules on hand tools, power tools, shop equipment, and special operations are given elsewhere in this text. It is much easier to understand and remember these rules when they are covered fully.

While working, constantly think of safety. Look for unsafe work habits, unsafe equipment, and other potentials for accidents. See **Figure 5-7.**

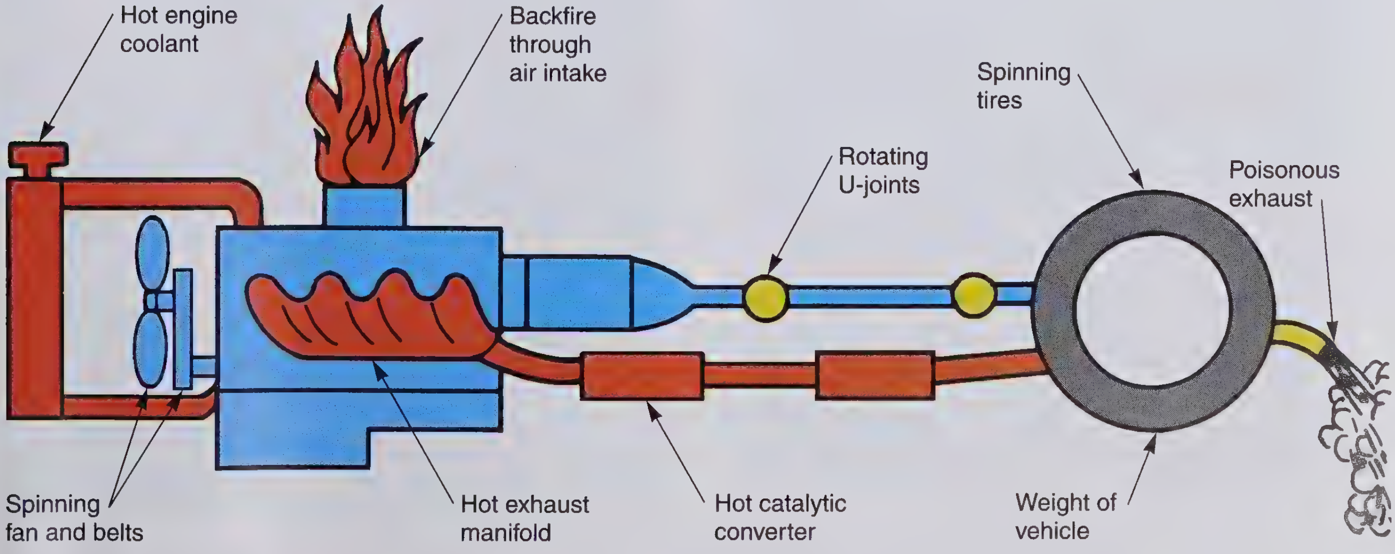
When working in an auto shop, you must always remember that you are surrounded by other technicians. This makes it even more important that you concentrate on safety to prevent injury to yourself and to others in the shop.

Types of Accidents

Basically, you should be aware of and try to prevent six kinds of accidents:

- Fires.
- Explosions.
- Asphyxiation (airborne poisons).
- Chemical burns.
- Electric shock.
- Physical injuries.

If an accident or injury occurs in the shop, notify your instructor immediately. Use common sense when deciding whether to get a fire extinguisher or to take other actions.



Hot engine coolant
Backfire through air intake
Spinning tires
Rotating U-joints
Poisonous exhaust
Spinning fan and belts
Hot exhaust manifold
Hot catalytic converter
Weight of vehicle

Figure 5-7. An automotive shop has the potential to be very dangerous. Just a few of the dangers present around an automobile are shown.

Fires

Fires are terrible accidents capable of causing severe injury and permanent scar tissue. Therefore, every precaution must be taken to prevent fires in the automotive shop.

There are numerous combustible substances (gasoline, oily rags, paints, thinners) found in an auto shop. ***Gasoline*** is by far the most dangerous and underestimated flammable in an auto shop. Gasoline has astonishing potential for causing a tremendous fire. Just a cupful of gasoline can instantly engulf a car in flames.

A few gasoline safety rules include:

- Store gasoline and other flammables in approved, sealed containers.
- When disconnecting a vehicle's fuel line or hose, wrap a shop rag around the fitting to keep fuel from squirting or leaking.
- Disconnect the battery before working on a fuel system.
- Wipe up gasoline spills immediately. Do not place oil absorbent (oil-dry) on gasoline because the absorbent will become highly flammable.
- Keep any source of heat away from fuel system parts.
- Never use gasoline as a cleaning solvent.

Oily rags can also start fires. Soiled rags should be stored in an approved safety can (can with lid).

Paints, thinners, and other combustible materials should be stored in a fire cabinet. Also, never set flammables near a source of sparks (grinder), flames (welder or water heater), or heat (furnace for example).

Note the location of all fire extinguishers in your shop. A few seconds can be a "lifetime" during a fire.

Electrical fires can result when a "hot wire" (wire carrying current to component) touches ground (vehicle frame or body). The wire can heat up, melt the insulation, and burn. Then, other wires can do the same. Dozens of wires could burn up in a matter of seconds.

To prevent electrical fires, always disconnect the battery when told to do so in a service manual. If possible, keep the battery disconnected during repairs.

Explosions

An ***explosion*** is the rapid, almost instant, combustion of a material that causes a powerful shock wave to travel through the shop. Several types of explosions are possible in an auto repair facility. You should be aware of these sources of sudden death and injury.

Hydrogen gas can surround the top of a car battery that is being charged or discharged (used). This gas is highly explosive. The slightest spark or flame can ignite the hydrogen gas, causing the battery to explode. Battery acid and pieces of the battery case can blow into your eyes and face. Blindness, facial cuts, acid burns, and scars can result. Always wear eye and face protection when working around a battery. See **Figure 5-8.**

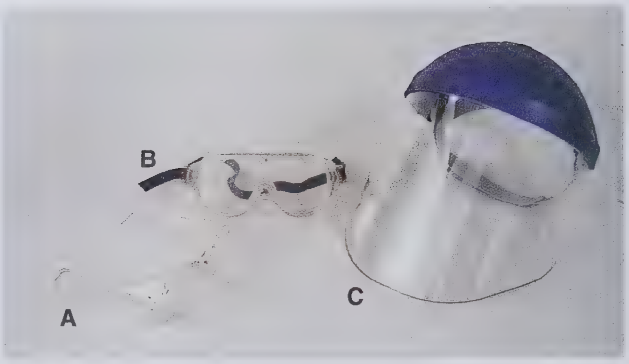


Figure 5-8. Wear approved eye and face protection when needed. A—Safety glasses. B—Safety goggles. C—Face shield.

Fuel tanks can explode, even seemingly empty ones. A drained fuel tank can still contain fuel gum and varnish. When this gum is heated and melts, it can emit vapors that may ignite.

Keep sparks and heat away from fuel tanks. When a fuel tank explodes, one side will usually blow out. Then, the tank will shoot across the shop as if shot out of a cannon. You or other workers could be killed or seriously injured.

Various other sources can cause shop explosions. For example, special sodium-filled engine valves, welding tanks, and propane-filled bottles can explode if mishandled. These hazards will be discussed in later chapters.

Warning!
Air bags should be handled with extreme care. If accidentally deployed, they can break bones or even kill. Carry them with the metal housing facing downward and away from your body. Keep all sources of electricity away from undeployed air bags.

Asphyxiation

Asphyxiation is caused by breathing toxic or poisonous substances. Mild cases of asphyxiation will cause dizziness, headaches, and vomiting. Severe asphyxiation can cause death.

The most common cause of asphyxiation in an auto shop is the exhaust gases produced by an automobile engine. *Exhaust gases are poison.* If a vehicle must be operated in an enclosed shop, connect the vehicle's tailpipe to the shop's exhaust ventilation system as shown in **Figure 5-9.** Also, make sure the exhaust ventilation system is turned *on.*

Discussed in related chapters, other shop substances are harmful if inhaled. A few of these harmful substances include asbestos (brake lining dust, clutch disc dust), parts cleaners, and paint spray. ***Respirators*** (filter masks) should be worn when working around any airborne impurities. Refer to **Figure 5-10.**

Chemical Burns

Solvents (parts cleaners), battery acid, and various other corrosive shop substances can cause ***chemical burns*** to the skin. Always read the directions on all chemical containers. Also, be sure to wear proper protective gear when handling solvents and other caustic materials. See **Figure 5-11.**

Carburetor cleaner (decarbonizing types), for example, is very powerful and can severely burn your skin in a matter of seconds. Wear rubber gloves when using carburetor cleaner. If a skin burn occurs, follow label directions.

Warning!
If your eyes are chemically burned, the material safety warning label may recommend flushing them with water. An ***eye flushing station*** is sometimes used to wash chemicals from your eyes after an accident.

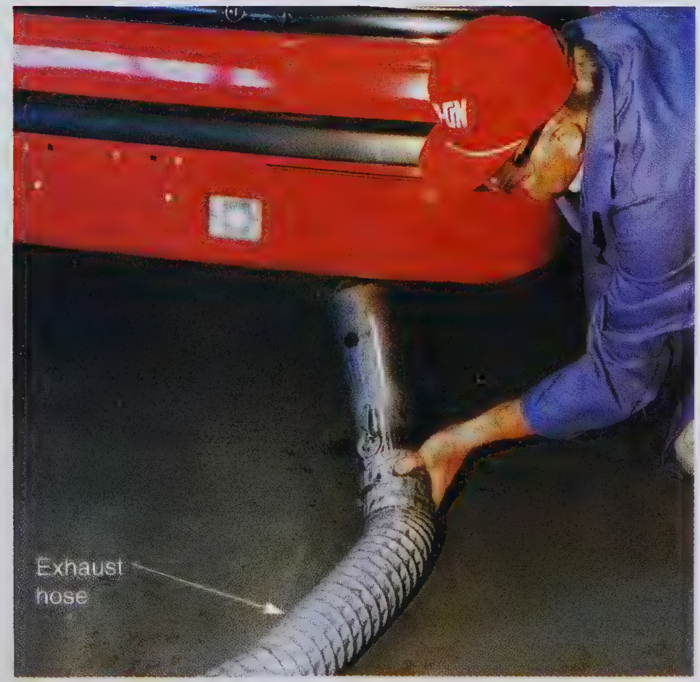

Figure 5-9. Place an exhaust hose over the tailpipe of any car running in an enclosed shop. This will prevent the shop from filling with deadly fumes. (Kent-Moore)

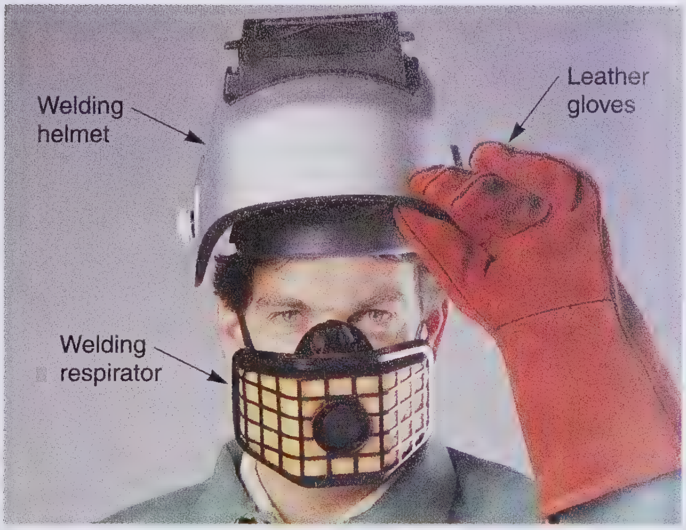

Figure 5-10. This technician is wearing a welding respirator to protect himself from toxic welding fumes. The welding helmet will shield the technician's face and eyes from hot sparks and the bright, "blinding" welding arc. (Lab Safety)

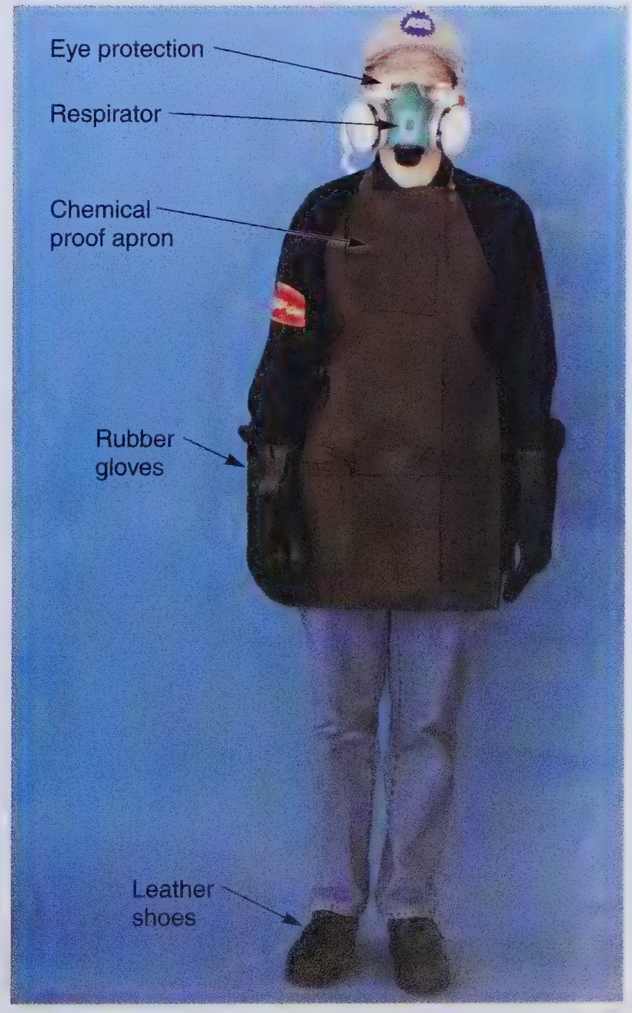

Figure 5-11. Always dress properly when handling substances that can cause chemical burns. Note that this technician is wearing rubber gloves, a chemical-proof apron, a respirator, and safety goggles.

Electric Shock

Electric shock is a result of electric current passing through parts of your body, causing injury or death. It can occur when using improperly grounded electric power tools.

Never use an electric tool unless it has a functional ***ground prong*** (third, round prong on plug socket). This prevents current from accidentally passing through your body. Also, never use an electric tool on a wet shop floor.

Warning!
Some late-model cars have heated windshields. The alternators on these vehicles are designed to put out more than 100 volts ac to quickly warm the windshield. This is enough voltage to cause electric shock. Work carefully around this high voltage.

Physical Injury

Physical injuries (cuts, broken bones, strained backs) can result from hundreds of different accidents. As a technician, you must evaluate every repair technique. Decide whether a particular operation is safe and take action as required.

For instance, if you are pulling on a hand wrench as hard as you can and the bolt will not turn, *stop!* Find another wrench that is larger. A larger tool has more leverage and is, therefore, safer. This approach will help prevent injuries and improve your mechanical abilities.

Warning!
Never overexert your back by improperly lifting heavy assemblies. Once you injure your back, it can take months to recover. Sometimes, surgery is needed to repair the damage. When lifting a heavy object, keep your back straight. Bend your knees and lift the item with your legs. If necessary, use power equipment to move heavy objects.

General Safety Rules

Listed are several general safety rules that should be followed at all times.

- Wear eye protection during any operation that could endanger your eyes. This would include operating power tools, working around a running car engine, carrying batteries, etc.
- Avoid anyone who does not take shop work seriously. Remember, a joker is "an accident just waiting to happen."
- Keep your shop organized. Return all tools and equipment to their proper storage areas. Never lay tools, creepers, or parts on the floor.
- Dress in an appropriate manner. Never wear loose clothing, neckties, shorts, or open-toed shoes when working in the shop. Remove rings, bracelets, necklaces, watches, and other jewelry. They can get caught in engine fans, belts, drive shafts, and other rotating parts, causing serious injury. Also, button or roll up long sleeves and secure long hair; they too can get caught in spinning parts.
- Never carry sharp tools or parts in your pockets. They can puncture the skin.
- Wear full face protection when grinding, welding, and performing other operations where severe hazards are present.
- Work like a professional. When learning auto repair, it is easy to get excited about your work. However, avoid working too fast. You could overlook a repair procedure or safety rule.
- Use the right tool for the job. There is usually a "best tool" for each repair task. Always be thinking about whether a different tool will work better than another, especially when you run into difficulty.
- Keep guards or shields in place. If a power tool has a safety guard, use it.
- Lift with your legs, not your back. There are many assemblies that are very heavy. When lifting, bend at your knees while keeping your back straight. On extremely heavy assemblies (transmissions, engine blocks, rear axles, transaxles), use a portable crane.
- Use adequate lighting. A portable shop light not only increases working safety, but it increases working speed and precision.
- Ventilate when needed. Turn on the shop ventilation fan anytime fumes are present in the shop.
- Never stir up asbestos dust. Asbestos dust (particles found in brake and clutch assemblies) is a powerful *cancer-causing agent.* Do *not* use compressed air to blow the dust from brake and clutch parts. Use an enclosed vacuum system to remove asbestos dust from brake assemblies, **Figure 5-12.**
- Jack up a vehicle slowly and safely. A car can weigh between one and two tons. Never work under a vehicle not supported by jack stands. It is *not* safe to work under a vehicle supported by only a floor jack. See **Figure 5-13.**

- Drive slowly when in the shop area. With all the other students and vehicles in the shop, it is very easy to have an accident.

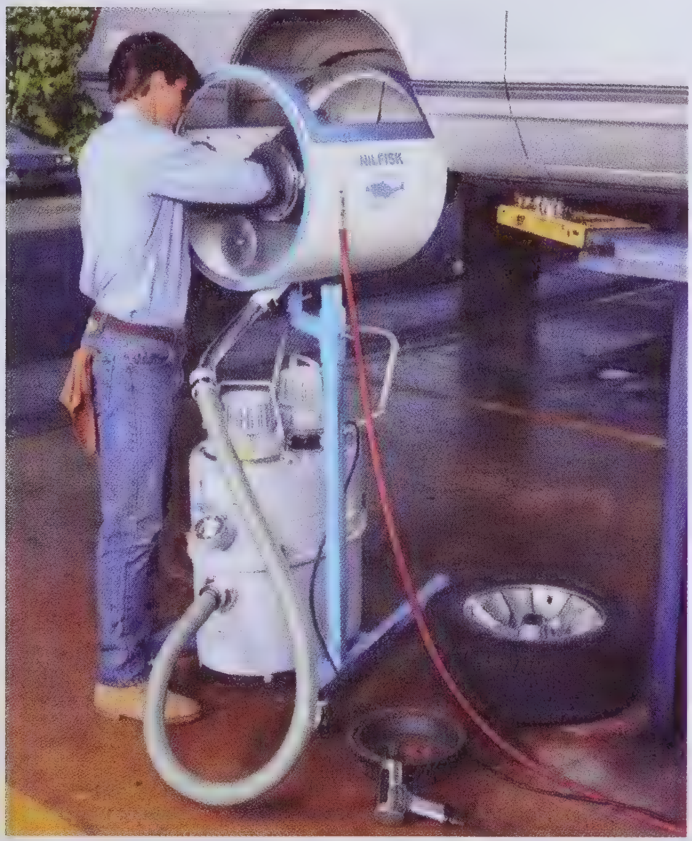

Figure 5-12. Asbestos dust from brakes and clutches can cause lung cancer. Always use a vacuum system like this one to remove asbestos dust from parts. Never blow asbestos dust into the shop area. (Nilfisk)

- Report unsafe conditions to your instructor. If you notice any type of hazard, let your instructor know about it.
- Stay away from engine fans. The fan on an engine is like a spinning knife. It can inflict serious injuries. Also, if a part or tool is dropped into the fan, it can fly out and hit someone. Electric fans can turn on even with the ignition key off!
- Respect running engines. When an engine is running, make sure the transmission is in park or neutral, the emergency brake is set, and the wheels are blocked. If these steps are not taken and the car is accidentally knocked into gear, it could run over you or a friend.
- Do not smoke in the auto shop. Smoking is a serious fire hazard, considering fuel lines, cleaning solvents, paints, and other flammables may be exposed.
- Read material safety data sheets when in doubt about any dangers. The material safety data sheet contains all the information needed to work safely with the hazardous material. See **Figure 5-14.**
- Obtain instructor permission before using any new or unfamiliar power tool, lift, or other shop equipment. If necessary, your instructor will give a demonstration.

Customer Relations

Most shop insurance policies do not cover customers who enter the shop work area. When informing customers that they are not allowed in the repair area, explain that the insurance company, not the shop, has made this rule. This will help prevent the customer from being offended by being told to leave the work area.

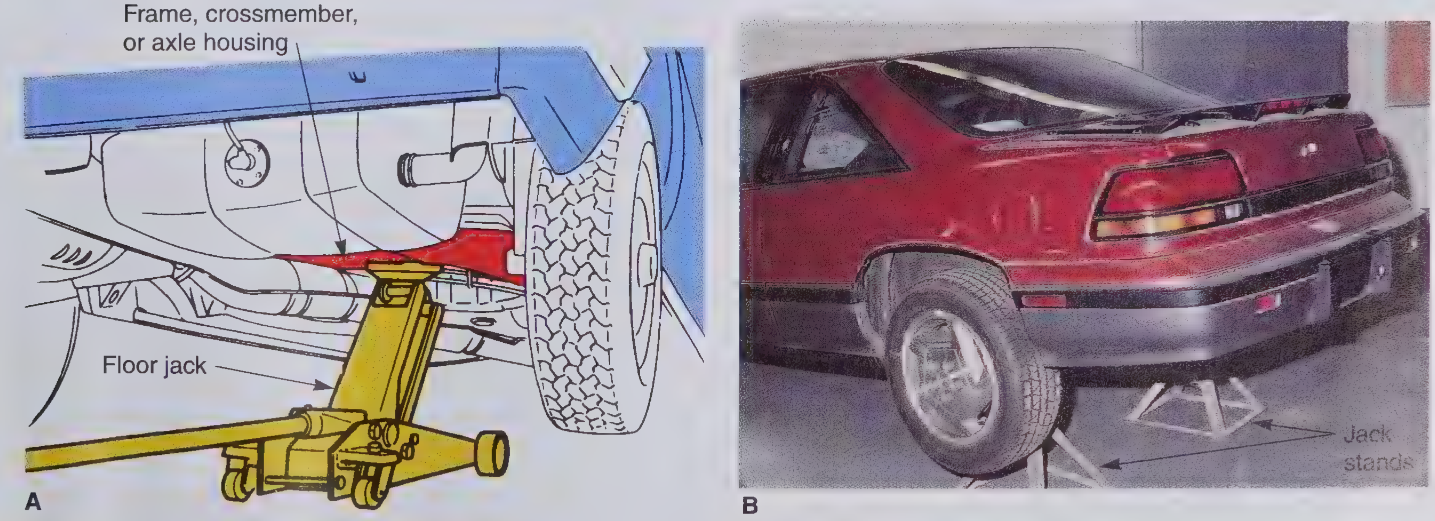

Figure 5-13. Never work under a car supported only by a floor jack. A—A jack must only be used for initial lifting. B—Jack stands are used to secure the car before working under it. Place the stands under the recommended lift points. (Subaru and Tech-Cor)

Summary

- An auto shop can be a very safe and enjoyable place to work. However, if basic safety rules are *not* followed, an auto shop can be very dangerous.
- The shop repair area includes any location in the shop where repair operations are performed.
- The toolroom is a shop area normally adjacent (next to) the main shop or classroom. It is used to store shop tools, small equipment, and supplies (nuts, bolts, oil).
- Every year, thousands of technicians are injured or killed on the job. Most of these accidents resulted from a broken safety rule.
- Fires are capable of causing instant and permanent scar tissue. There are numerous combustible substances found in an auto shop.
- Gasoline is by far the most dangerous and often underestimated flammable in an auto shop.
- Electrical fires can result when a "hot wire" (wire carrying current to component) touches ground (vehicle frame or body).
- An explosion is the rapid combustion of a material, which causes a powerful shock wave to travel out through the shop.
- Asphyxiation is caused by breathing toxic or poisonous substances in the air.
- Respirators should be worn when working around any kind of airborne impurities.
- Electric shock results when electric current passes through your body, causing injury or death.
- Physical injuries (cuts, broken bones, strained backs) can result from a variety of accidents.

Review Questions—Chapter 5

Please do not write in this text. Place your answers on a separate sheet of paper.

1. List four safety rules to follow when using a vehicle lift.
2. A(n) _____ _____ is used when working on a car's steering and suspension systems. It has special equipment for aligning the vehicle's wheels.

3. _____ is the most common and dangerous flammable found in an auto shop.
4. What causes an electrical fire in an automobile?
5. Car batteries can explode. True or False?
6. Which of the following cannot cause electric shock?
   (A) A missing ground prong on cord.
   (B) Using an electric drill on wet floor.
   (C) Using electric tools with a ground prong.
   (D) None of the above.
7. Explain what must be done to prevent physical injuries.
8. If you are pulling on a wrench as hard as you can and the fastener does *not* turn, what should you do to prevent injury?
9. When lifting heavy objects, always lift with your _____.
   (A) arms
   (B) legs
   (C) back
   (D) None of the above.
10. List 20 general safety rules.

ASE-Type Questions

1. In which auto shop area would an exhaust system repair most likely be done?
   (A) Shop stall.
   (B) Grease rack.
   (C) Alignment rack.
   (D) Outside work area.
2. Rules to remember when using gasoline include each of the following *except:*
   (A) store gas in approved containers.
   (B) keep gas away from sources of heat.
   (C) use quick dry to absorb any gas spills.
   (D) never use gasoline as a cleaning solvent.
3. Which of the following is a possible source of explosions in an auto shop?
   (A) Fuel tanks.
   (B) Car batteries.
   (C) Welding tanks.
   (D) All the above.
4. Asphyxiation can be caused by:
   (A) touching a current-carrying wire.
   (B) improper lifting techniques.
   (C) breathing toxic substances.
   (D) None of the above.
5. Asbestos dust, which can cause cancer, is found in:
   (A) fuel tanks.
   (B) transmissions.
   (C) propane-filled bottles.
   (D) brake and clutch assemblies.
6. A respirator is a:
   (A) filter mask.
   (B) type of chemical burn.
   (C) machine guard.
   (D) device to put out small fires.
7. Eye protection should be worn when:
   (A) carrying batteries.
   (B) operating power tools.
   (C) working by a running engine.
   (D) All of the above.
8. Which of the following is *not* a good tip when dressing for work?
   (A) Secure long hair.
   (B) Roll up long shirt sleeves.
   (C) Make sure all jewelry fits well.
   (D) Do not carry sharp tools in pocket.
9. An engine needs to be moved. Technician A says two people can slide the engine out of the way. Technician B says that an engine crane should be used to move the engine. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. When removing asbestos dust from parts, Technician A believes a vacuum system should be used. Technician B believes dust should be blown away using compressed air. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Activities for Chapter 5

1. Sketch out a floor plan of your shop and label the different areas. Study the safety cautions in this chapter and determine if there are any safety hazards. Mark their location on the floor plan.
2. On the same floor plan, mark the location of fire extinguishers, exits, and water fountains.
3. Examine a fire extinguisher in the shop area; read the instructions carefully. Demonstrate its use.

6 Automotive Measurement and Math

After studying this chapter, you will be able to:

- Describe both customary and metric measuring systems.
- Identify basic measuring tools.
- Describe the use of common measuring tools.
- Use conversion charts.
- List safety rules relating to measurement.
- Summarize basic math facts.
- Correctly answer ASE certification test questions that require a basic understanding of measurement and math.

As a vehicle is driven, many of its moving parts slowly wear out. With enough part wear, mechanical failures and performance problems result. Manufacturers give ***specifications,*** or ***"specs,"*** which are maximum wear limits and dimensions of important parts. If the measurements are *not* within these specifications, the part must be adjusted, repaired, or replaced. Therefore, a technician must be able to make accurate measurements.

This chapter introduces the most important types of measurements performed by a service technician. General measuring tools and methods are explained using both customary and metric systems. Work-related math skills are also covered. Study this chapter very carefully. It prepares you for other textbook chapters and for hundreds of in-shop tasks.

Measuring Systems

Two ***measuring systems*** are commonly used when working in the auto shop: the customary measuring system (inches, pounds, etc.) and the metric (SI) measuring system (millimeters, grams, etc.) The customary measuring system is also called the U.S. customary units system or the English system. Most countries use the metric system. The customary system is mainly used in the United States. However, the United States uses the metric system as well. All vehicles manufactured in the U.S. by foreign companies and many vehicles made by U.S. companies use metric bolts, nuts, and other parts. Manufacturer's specifications are often given in both customary and metric values for U.S. made vehicles. **Figure 6-1** summarizes and compares the two measuring systems.

Customary Measuring System

The ***customary measuring system*** originated from sizes taken from parts of the human body. For example,

Quantity	Customary (abbreviation)	Metric (abbreviation)
Length	Inch (in) Foot (ft) Mile (mi)	Meter (m)
Weight (mass)	Ounce (oz) Pound (lb)	Kilogram (kg)
Area	Square inch (sq-in)	Square meter (m^2)
Dry volume	Cubic inch (cu-in)	Cubic meter (m^3) Cubic centimeter (cc)
Liquid volume	Ounce (oz) Pint (pt) Quart (qt) Gallon (gal)	Liter (L) Cubic centimeter (cc)
Road speed	Miles per hour (mph)	Kilometer per hour (km/h)
Torque	Foot-pounds (ft-lb)	Newton meter (N·m)
Power	Horsepower (hp)	Kilowatt (kW)
Pressure	Pounds per square inch (psi)	Kilopascal (kPa)
Temperature	Degrees fahrenheit (°F)	Degrees celsius (°C)

Figure 6-1. This chart compares U.S. customary and metric values. Study them carefully.

the width of the human thumb was used to standardize the inch, **Figure 6-2.** The length of the human foot was used to standardize the foot as 12 inches. The distance between the tip of a finger and nose was used to set the standard for the yard as 3 feet. Obviously, these are not very scientific standards since these distances vary from person to person.

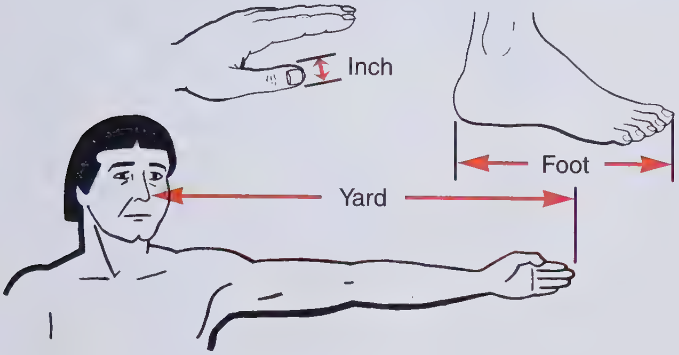

Figure 6-2. The customary system was originally based on parts of the human body. (Starrett)

Metric (SI) Measuring System

The ***metric (SI) measuring system*** uses a power of 10 for all basic units. It is a simpler and more logical system than the customary system. Computation often requires nothing more than moving the decimal point. For instance, one meter equals 10 decimeters, 100 centimeters, or 1000 millimeters.

Conversion Charts

A measuring system ***conversion chart*** is needed when changing a value from one measuring system to another, such as when changing from inches to centimeters, gallons to liters, or liters to gallons. A conversion chart lets the technician quickly convert customary values to equivalent metric values, or vice versa. One is shown in **Figure 6-3.**

A ***decimal conversion chart*** is commonly used to find equivalent values for fractions, decimals, and millimeters. See **Figure 6-4.** Fractions are only accurate to about 1/64 of an inch. For smaller measurements, either

Measurement	When you know:	You can find:	If you multiply by:
Length	inch (in)	millimeter (mm)	25.4
	foot (ft)	meter (m)	.3
	yard (yd)	meter (m)	.9
	mile (mi)	kilometer (km)	1.6
	millimeter (mm)	inch (in)	.04
	centimeter (cm)	inch (in)	.39
	meter (m)	yard (yd)	1.09
	kilometer (km)	mile (mi)	.6
Pressure	pounds per square inch (psi)	kilopascal (kPa)	6.89
	kilopascal (kPa)	pounds per square inch (psi)	.145
Power	horsepower (hp)	kilowatt (kW)	.746
	kilowatt (kW)	horsepower (hp)	1.34
Torque	foot-pounds (ft-lb)	Newton-meter (N·m)	1.36
	Newton-meter (N·m)	foot-pounds (ft-lb)	.74
Volume	quart (qt)	liter (L)	.95
	liter (L)	quart (qt)	1.06
	cubic inch (cu-in)	liter (L)	.016
	liter (L)	cubic inch (cu-in)	61.02
Mass	ounce (oz)	gram (g)	28.35
	gram (g)	ounce (oz)	.035
	pound (lb)	kilogram (kg)	.45
	kilogram (kg)	pound (lb)	2.20
Speed	miles per hour (mph)	kilometers per hour (km/h)	1.61
	kilometers per hour (km/h)	miles per hour (mph)	.62

Figure 6-3. To convert from one system to another, multiply the known value by the number in right column. This will give an approximately equal value.

Figure 6-4. A decimal conversion chart is commonly used in the auto shop. This chart lets you interchange fractions, decimals, and millimeters. What are equal decimal and millimeter values for 1/4″, 5/32″, 43/64″, and 7/8″? (Parker Hannifin Corp.)

decimals or millimeters should be used. A decimal conversion chart may be needed to change a fractional measurement to a decimal measurement.

Measuring Tools

There are various tools used by a technician to make accurate measurements. Common measuring tools include the steel rule, caliper, micrometer, and dial indicator. Most of these are available in both customary and metric units. These and other tools are covered in the next sections.

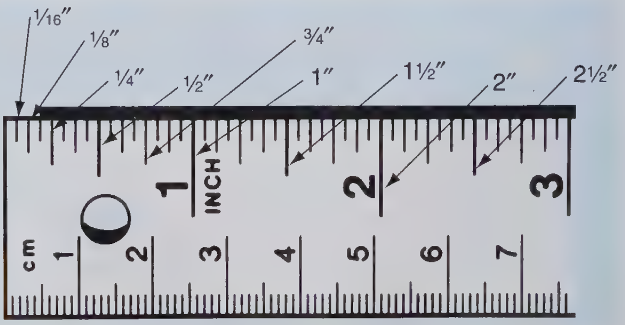

Figure 6-5. Compare inches to centimeters. Ten millimeters equals one centimeter. Twenty-five millimeters is a little less than one inch. The customary rule is divided into 1/16″ fractions. (Fairgate)

Steel Rule

A ***steel rule***, or ***scale***, is frequently used to make low-precision linear measurements. It is accurate to about 1/64″ (0.4 mm) in most instances. A ***customary rule*** has number labels that represent full inches, **Figure 6-5.** The smaller, unnumbered lines, or graduations, represent fractions of an inch, such as 1/2″, 1/4″, 1/8″, and 1/16″. The shortest graduation lines represent the smallest fractions. In **Figure 6-5,** this is 1/16″. A ***metric rule*** normally has lines or divisions representing millimeters (mm). Each numbered line usually equals 10 mm, or 1 cm (centimeter). This is also shown in **Figure 6-5.**

A ***pocket rule,*** or ***pocket scale,*** is typically 6″ long. It is small enough to fit in your shirt pocket. A ***combination square*** is a sliding square that is mounted on a steel rule. It is needed when the rule must be held perfectly square against the part being measured. See **Figure 6-6.**

A ***tape measure,*** or ***tape rule,*** extends to several feet or meters in length. It is sometimes needed for large distance measurements during body, suspension, and exhaust system repairs. Look at **Figure 6-7.** A ***yardstick*** or ***meterstick*** is a rigid measuring device used for large lineal measurements up to one yard or one meter.

Dividers

Dividers look like a drafting compass, but have straight, sharply pointed tips, **Figure 6-8A.** They are commonly used for layout work on sheet metal parts. The sharp points can scribe circles and lines on sheet metal and plastic. Dividers can also be used to transfer and make surface measurements.

Calipers

An ***outside caliper*** is used to make external measurements when 1/64″ (approximately 0.40 mm) accuracy is sufficient. See **Figure 6-8B.** The caliper is fitted over the outside of parts and adjusted so that each tip just touches the part. Then, the caliper is held against a rule and the distance between the tips is measured to determine part size.

An ***inside caliper*** is designed for internal measurements in holes and other openings, **Figure 6-8C.** It is placed inside a hole and adjusted until the tips just touch

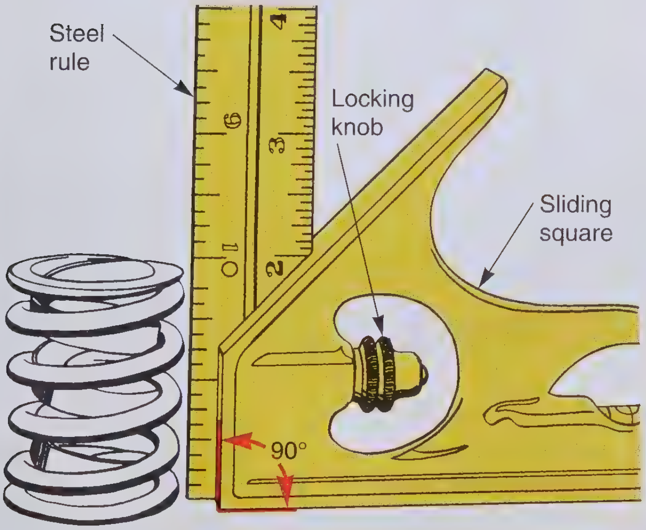

Figure 6-6. A combination square is needed when the rule must be held perfectly parallel to the part. (Cadillac)

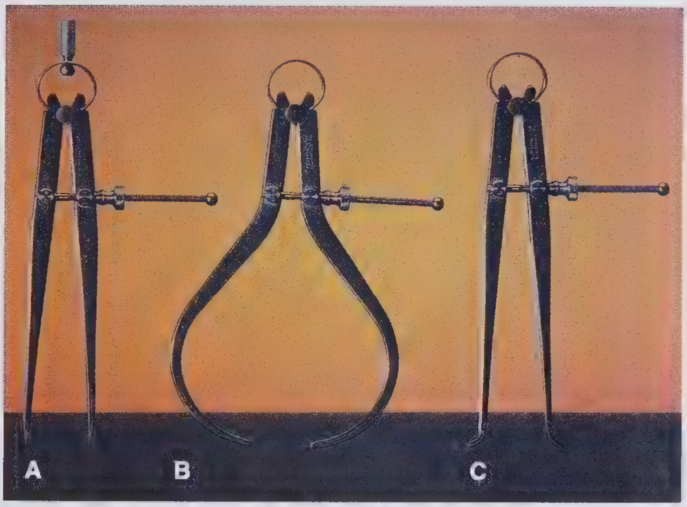

Figure 6-8. A—Dividers have sharp points for measuring or marking on metal parts. B—An outside caliper for measurements on the outside of a part. C—An inside caliper for internal measurements. (Starrett)

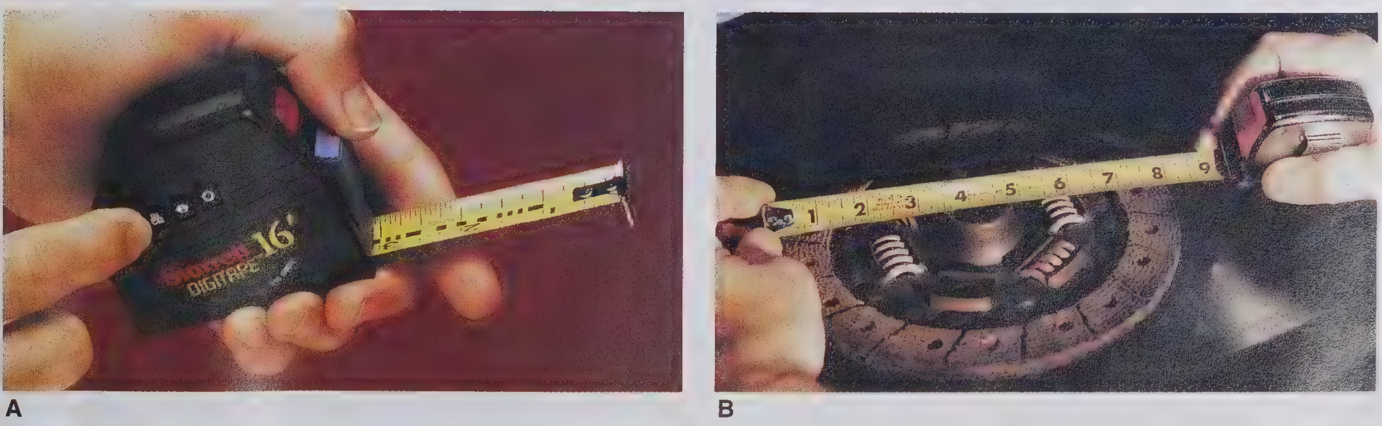

Figure 6-7. A—A digital-reading tape measure. B—A tape measure is used to make large straight-line measurements.

the part. Then, it is held against a rule and the distance between the tips is measured.

A ***vernier caliper*** is a sliding measuring device that can make inside, outside, and depth measurements with considerable accuracy. One is pictured in **Figure 6-9.** Many vernier calipers can take measurements as small as 0.001″ (0.025 mm). Some vernier calipers have a dial gauge attached. The dial makes the “thousandths” part of a measurement easier to read. A vernier caliper is fast and easy to use, making it a very useful tool for the automotive technician to have.

Figure 6-9. A vernier caliper can be used to quickly check inside, outside, and depth measurements. (Starrett and K-D Tools)

Micrometers

A ***micrometer,*** nicknamed a ***mike,*** is used to make very accurate measurements. It can measure to one ten-thousandth of an inch (.0001″) or one thousandth of a millimeter (0.001 mm). There are several types of mikes used in automotive service and repair. These include outside, inside, and depth micrometers. In addition, a telescoping gauge, or a hole gauge, may be used with a micrometer.

Anvil
Spindle
Sleeve
Thimble
Decimal readout
Frame

Figure 6-10. A micrometer is the precision measuring tool most commonly used by a technician. This one is easy to use because it has a digital readout. (Starrett)

An ***outside micrometer*** is used for measuring external dimensions, diameters, or thicknesses, **Figure 6-10.** To use an outside micrometer, place it around the outside of the part. Then, turn the thimble until both the spindle and anvil are lightly touching the part, as in **Figure 6-11.** Finally, read the graduations on the hub and thimble to determine the measurement. Reading a micrometer is discussed in the next section.

An ***inside micrometer*** is used for internal measurements of large holes, cylinders, or other part openings, **Figure 6-12A.** To use an inside micrometer, place it

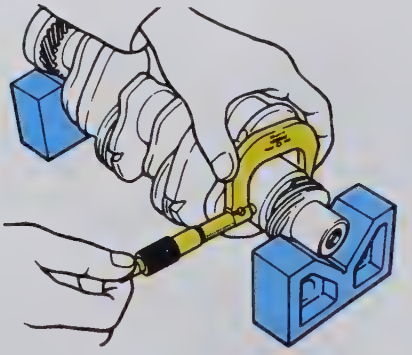

Figure 6-11. To use a micrometer, gently rotate the thimble to screw the spindle into the part. Move the mike over the part while holding it squarely. When you feel a slight drag, remove the mike and read the measurement. (Subaru)

inside the opening. Then, adjust the micrometer until it just touches the walls of the opening. Finally, remove the micrometer and read the measurement. The inside micrometer is read in the same manner as an outside mike.

A ***depth micrometer*** is helpful when precisely measuring the depth of an opening. Look at **Figure 6-12B.** The base of the micrometer is positioned squarely on the part. Then, the thimble is turned until the spindle contacts the bottom of the opening. The depth micrometer is read in the same way as an outside micrometer. However, the hub markings are *reversed.*

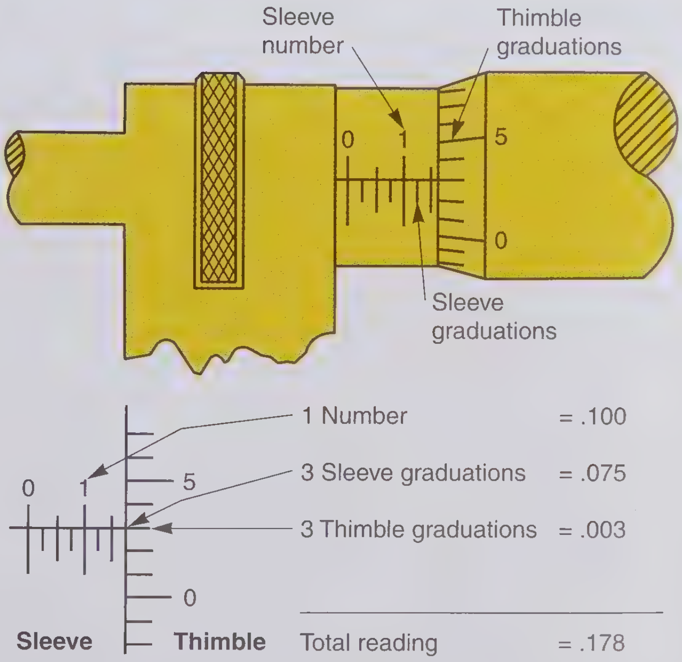
A ***telescoping gauge*** is used to measure internal part bores or openings, **Figure 6-12C.** To use the gauge, compress the spring-loaded extensions and lock them with the thumb wheel. Then, insert the gauge into the opening and release the thumb wheel. The extensions "snap" to the edges of the opening. Use the thumb wheel to lock the extensions to the size. Finally, use an outside micrometer to measure the distance across the extensions.

A ***hole gauge*** is used for measuring very small holes in parts. To use a hole gauge, first loosen the thumb wheel. Then, insert the gauge into the hole and tighten the thumb wheel until the gauge just touches the part. Finally, remove the gauge and measure it with an outside micrometer.

Reading a Customary Micrometer

To read a customary micrometer, follow the four steps listed below. Refer to **Figure 6-13.**

1. Note the *largest* number visible on the micrometer sleeve. Each number equals 0.100″ (2 = 0.200″, 3 = 0.300″, 4 = 0.400″).
2. Count the number of graduation *lines* to the right of the sleeve number. Each full sleeve graduation equals 0.025″ (2 full lines = 0.050″, 3 = 0.075″).
3. Note the *thimble graduation* aligned with the horizontal sleeve line. Each thimble graduation equals 0.001″ (2 thimble graduations = 0.002″, 3 = 0.003″). Round off when the sleeve line is not directly aligned with a thimble graduation.
4. Add the decimal values from steps 1, 2, and 3. Also, add any full inches. This sum is the micrometer reading in inches.



Sleeve number
Thimble graduations

0
Sleeve
Thimble

Figure 6-13. To read a micrometer, read the sleeve number first. Then, read the sleeve graduations. Finally, read the thimble number. Add these three values to obtain the reading. (Starrett)

Reading a Metric Micrometer

Micrometers are also available in metric units. They are similar to customary micrometers but have graduations and numbers in metric values. For example, one revolution of the thimble equals 0.500 mm. To read a metric micrometer, follow the four steps given below. Refer to **Figure 6-14.**

1. Read the *largest* number visible on the micrometer sleeve. Each number equals 1.00 mm (2 = 2.00 mm, 3 = 3.00 mm).
2. Count the number of *graduation lines* (both above and below the horizontal sleeve line) to the right of the sleeve number. Each full sleeve graduation equals 0.50 mm (2 = 1.00 mm, 3 = 1.50 mm).
3. Read the *thimble graduation* aligned with the horizontal sleeve line. Each thimble graduation equals 0.01 mm (2 = 0.02 mm, 3 = 0.03 mm).
4. Add the values from the steps 1, 2, and 3. This sum is the metric micrometer reading in millimeters.

Micrometer Rules

A few important micrometer rules to remember include:

- Never drop or overtighten a micrometer. It is very delicate, and its accuracy can be thrown off easily.
- Store micrometers where they cannot be damaged. Keep them in wooden or plastic storage boxes.
- Grasp the micrometer frame in your palm and turn the thimble with your thumb and finger. The measuring faces should just drag on the part being measured.
- Hold the micrometer squarely with the work or false readings can result. Closely watch how the spindle is contacting the part.
- Rock or swivel the micrometer as it is touched on round parts. This will ensure that the most accurate diameter measurement is obtained.
- Place a thin film of oil on the micrometer during storage. This will keep the tool from rusting.
- Always check the accuracy of a micrometer if it is dropped or struck, or after a long period of use. Standardized gauge blocks are used for checking micrometer accuracy.

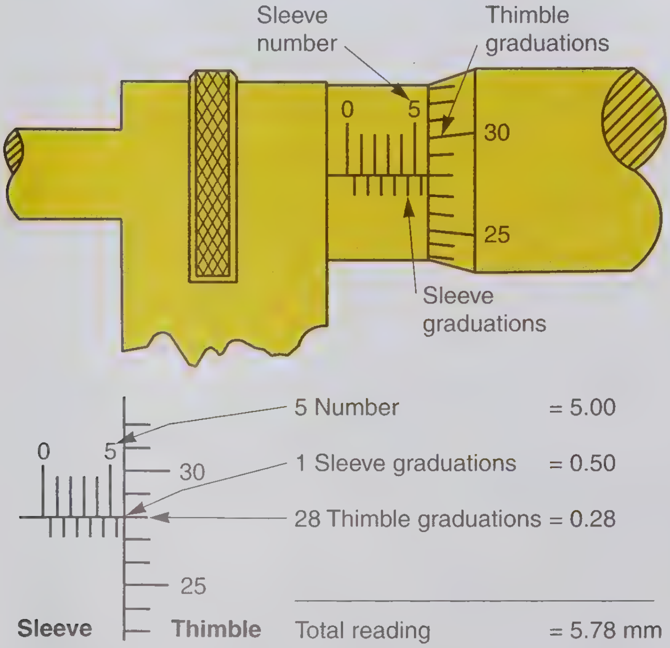

Figure 6-14. A metric micrometer is read like a customary micrometer. However, metric values are used for the sleeve and thimble. (Starrett)

Tech Tip!
An easy way to practice using a micrometer is to measure the thickness of feeler gauge blades. Since the thickness is printed on the blades, you can read the mike and compare your results to the actual thickness of each blade.

Feeler Gauges

A ***feeler gauge*** is used to measure small clearances or gaps between parts. There are two basic types of feeler gauges: flat feeler gauges and wire feeler gauges. Both types are available in customary and metric versions.

A ***flat feeler gauge*** has precision-ground steel blades of various thicknesses, **Figure 6-15A.** Thickness is written on each blade in thousandths of an inch and/or in hundredths of a millimeter. A flat feeler gauge is normally used to measure distances between *parallel surfaces.*

A ***wire feeler gauge*** has precise-size wires labeled by diameter or thickness, **Figure 6-15B.** It is normally used to measure slightly larger spaces or gaps than a flat feeler gauge. A wire gauge is also used for measuring the distance between *unparallel* or *curved surfaces.*

Using a Feeler Gauge

To measure with either type feeler gauge, find the gauge blade or wire that just fits between the two parts being measured. The gauge should drag slightly when pulled between the two surfaces. The size given on the gauge is the clearance between the two components.

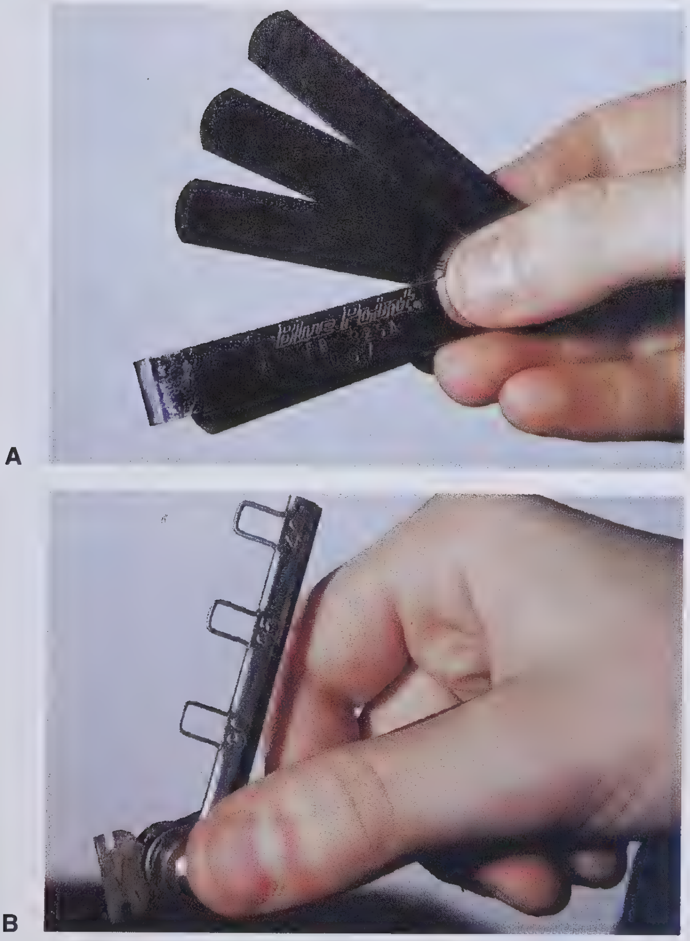

Figure 6-15. A—Flat, or blade, feeler gauge set. B—Wire feeler gauge set.

Dial Indicator

A ***dial indicator*** is used to measure part movement in thousandths of an inch (hundredths of a millimeter). See **Figure 6-16.** The needle on the indicator face registers the amount of plunger movement. A dial indicator is frequently used to check gear teeth backlash (clearance), shaft end play, cam lobe lift, and similar kinds of part movements. A magnetic mounting base or clamp mechanism is normally used to secure the dial indicator to or near the work. Be careful not to damage a dial indicator. It is very delicate.

Using a Dial Indicator

To measure with a dial indicator, follow these basic rules:

1. Mount the indicator securely and position the dial plunger parallel with the movement to be measured.
2. Partially compress the indicator plunger before locking the indicator into place. This allows part movement in either direction to be measured.

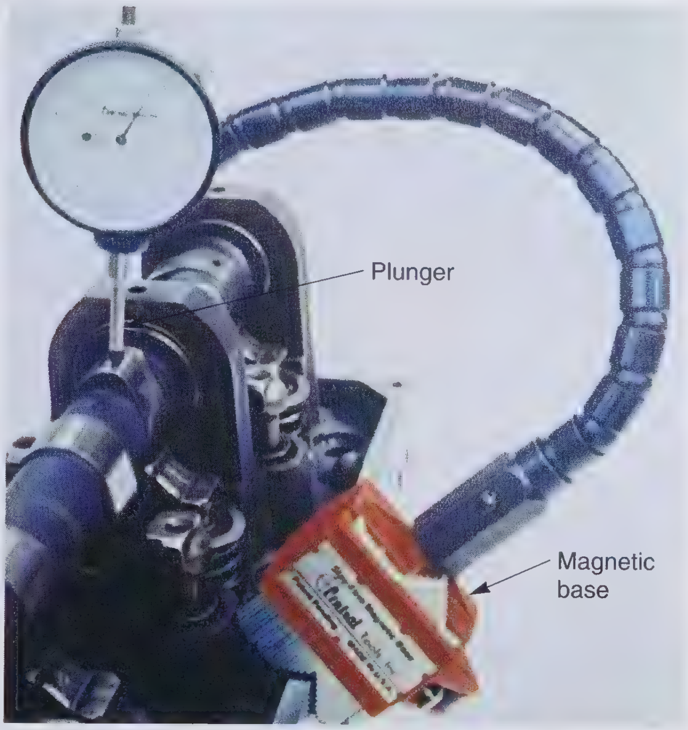

Figure 6-16. A dial indicator is used when measuring part movement. In this example, the tool is set up to check height and wear of a camshaft lobe. The cam is rotated and the indicator reading is compared to specs to find wear. (Central Tool Co.)

3. Move the part back and forth or rotate the part while reading the indicator.
4. Subtract the lowest reading from the highest reading. The result equals the distance the part moved, the clearance, or the runout.

Other Measurements and Measuring Tools

A service technician may make other types of measurements and use other types of measuring tools than those discussed to the point. Some of these are discussed in the next sections. More specialized measurements are covered in later chapters.

Angle Measurement

A circle is divided into 360 equal parts called ***degrees,*** **Figure 6-17.** Degrees are abbreviated with "deg." or the degree symbol (°). One-half of a circle equals 180°, one-quarter of a circle equals 90°, and one-eighth of a circle equals 45°. Specifications are normally given in degrees when you are measuring rotation of a part or an angle formed by a part. Later text chapters discuss this.

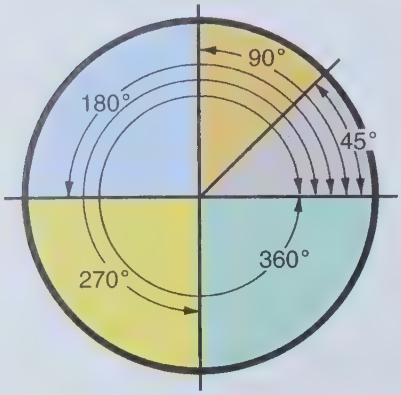

Figure 6-17. The amount of rotation and angles are measured in degrees. Note how many degrees are in a full circle and in fractions of a circle.

Temperature Measurement

Temperature gauges, or ***thermometers,*** are used to measure temperature. For example, air conditioning output temperature or radiator temperature may need to be determined. The temperature obtained with the gauge can be compared to specifications. Then, if the temperature is too low or too high, you know that a repair or adjustment is needed. Temperature gauges are available that can read in either customary ***Fahrenheit*** (F) or metric ***Celsius*** (C), **Figure 6-18.**

Torque Wrenches

A ***torque wrench*** is not used for taking measurements. Rather, it is used to apply a specific amount of turning force to a fastener, such as a bolt or nut. A torque wrench uses the principle illustrated in **Figure 6-19.** Torque wrench scales usually read in foot-pounds (ft-lb) and Newton-meters (N•m). The three general types of torque wrenches are the ***flex bar, dial indicator,*** and ***ratcheting*** types. These are shown in **Figure 6-20.**

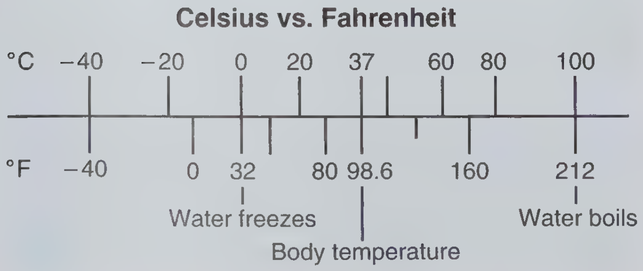

Figure 6-18. Study the relationship between customary Fahrenheit (°F) and metric Celsius (°C) temperature values.

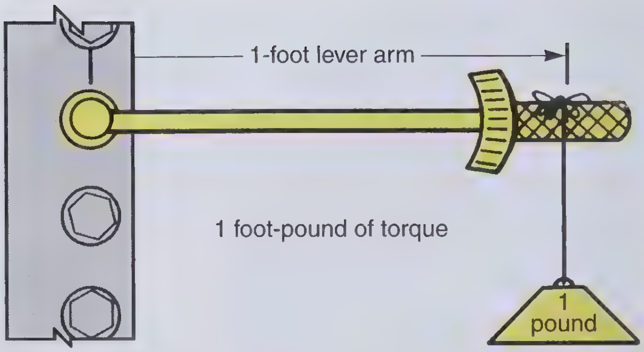

Figure 6-19. One foot-pound equals one pound of pull on a one-foot-long lever arm. This provides a means of measuring torque, or twisting motion.

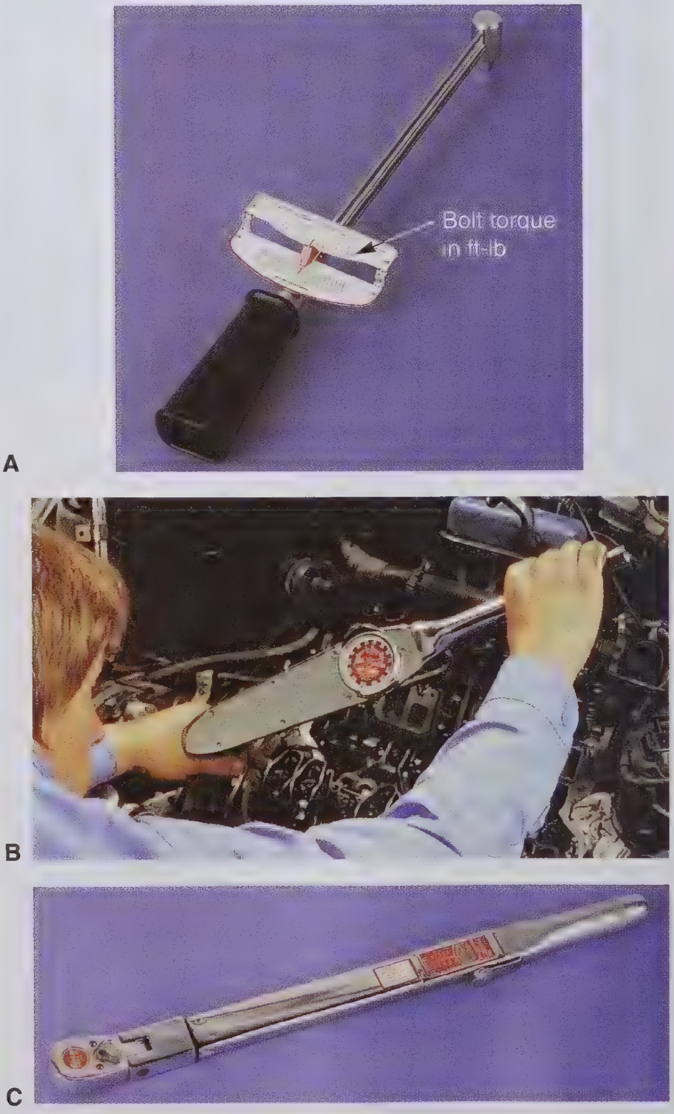

Figure 6-20. Different torque wrench types. A—A flex bar torque wrench uses a bending metal beam to make the pointer read torque on the scale. B—A dial indicator torque wrench is very accurate. C—A ratcheting, or snap-type, torque wrench is fast. The torque value is set by turning the handle. Then, the fastener is tightened until a click or popping sound is heard.

Pressure Gauge

A ***pressure gauge*** is used to measure air and fluid pressure in various systems and components. For example, pressure gauges may be used to check tire air pressure, fuel pump pressure, air conditioning system pressure, or engine compression stroke pressure. Look at **Figure 6-21.** A pressure gauge normally reads in pounds per square inch (psi), kilograms per square centimeter (kg/cm^2), or kilopascals (kPa).

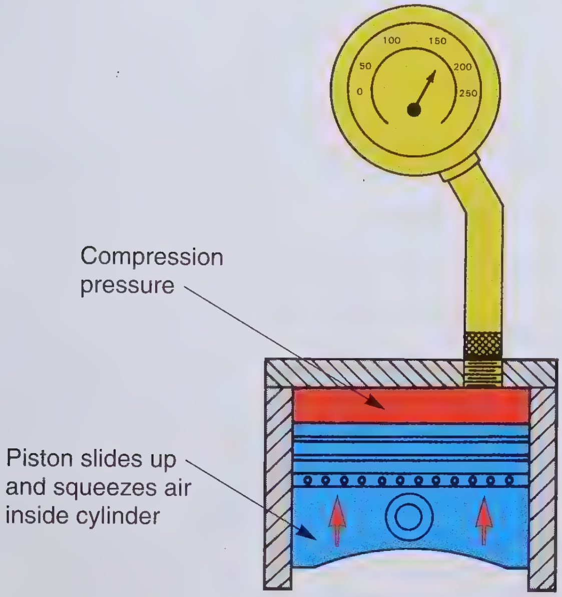

Figure 6-21. A technician must frequently measure pressure. This example shows a gauge being used to measure the pressure developed during the engine compression stroke. If the pressure is not high enough, engine mechanical problems are indicated.

Vacuum Gauge

A ***vacuum gauge*** is used to measure negative pressure, or vacuum. It is similar to a pressure gauge. However, the gauge reads in inches of mercury (in./hg.) or metric kilograms per square centimeter (kg/cm^2). For example, a vacuum gauge is used to measure the vacuum in an engine's intake manifold. If the reading is low or fluctuating, it may indicate an engine problem.

Using Basic Mathematics

Automotive technicians often use mathematics during the service and repair of vehicles. Technicians must be able to do the four basic math operations: addition, subtraction, multiplication, and division. They must also be able to work with fractions and decimals.

Math skills are needed when working with specifications. For example, if you are working on an engine, you may need to measure piston diameter and cylinder diameter. By subtracting piston diameter from cylinder diameter, you would find piston clearance. This math must be done properly if the engine is to run normally after repairs.

You will also use math when filling out work orders. You must calculate part prices, labor charges, tax percentage, and total charges.

The following section will quickly review basic math calculations.

Addition

Addition is the combining of two or more numbers to find the total quantity or number of something. The result of the addition process is called the ***sum*** or the ***total.*** A plus sign (+) is used to indicate that the numbers are to be added. Numbers to be added may be written two ways:

in a string: 5 + 3 + 4 = 12 *(sum)*
or
in a column:
5
3
+ 4
12 *(sum)*

When there are large numbers or a long series of numbers, it is best to write them in a column so sums of 10 and over can be carried to the next column. Always start adding from the right-hand column so that sums exceeding 9 can be carried from that column to the next column to the left:

122 - - 2 *First, add the right-hand column.*
804 - - 4
644 - - 4
+829 - - 9
19

1 *Since the total is 19, place the "9" underneath the right-hand column and add the "1" to the next column. Add up the 2nd column.*
- 2 -
- 0 -
- 4 -
- 2 -
99

1 - - *Now, add up the next column to the left and place the sum below that column.*
8 - -
6 - -
8 - -
2399 *(Answer is 2399)*

Addition is used in adding up the cost of parts and labor when preparing a customer's bill. If, for example, parts total $125, labor charges are $95, and tax is $8, the total bill would be $228.

Subtraction

Subtraction is taking away a certain quantity from another. The amount that is left after subtracting is called the ***remainder*** or the ***difference.*** The minus sign (–) indicates that the number to the right of it is to be subtracted. Subtraction problems might be written in two ways:

in a string: 495 – 125 = 370 *(remainder)*
or
in a column: 495
– 125
370 *(remainder)*

Subtraction might be used in determining a customer's bill. It might also be used by the technician to check the deductions made on a paycheck for taxes and social security. Suppose that a customer's bill totaled $253, but there had been a $25 deposit before the work was done. To determine the amount due, you would subtract $25 from $253 ($253 – $25).

$253
– 25
$228

Notice that we had to borrow 10 from the second column, since 5 cannot be subtracted from 3.

Division

To find out how many times one number is contained in another, we use ***division.*** The division sign (÷) indicates that one number is to be divided by another. The number being divided is called the ***dividend.*** The number a dividend is divided by is called the ***divisor.*** The answer is called the ***quotient.*** A division problem can be written one of three ways:

in a string: 860 ÷ 10 = 86 *(quotient)*

86 *(quotient)*
or: 10 / 860

or: $\frac{860}{10}$ = 86 *(quotient)*

The technician must use division frequently in an automotive repair facility. For example, suppose that 10 fuel pumps had been ordered and placed in stock. The total bill for the pumps came to $860. What is the cost of each fuel pump?

The cost of each fuel pump is found by dividing $860 (total cost) by 10 (number of pumps). The cost of each pump is $86. This information would be used to determine what the customer would be charged for the pump.

When dividing, not all answers come out to full numbers. In such cases, a decimal point is placed to the right of the last number of the dividend. A decimal point is also placed in the answer directly above the decimal point in the dividend. One or more zeros may be added to the dividend, depending on how many places the decimal number must carried out. For example, suppose that the cost of the fuel pumps in the previous example came to $865 instead of $860.

86.50 *(quotient—each pump cost $86.50)*
10 / 865.00
80
65
60
50
50
0

Multiplication

Multiplication is a shortcut for adding the same number over and over. Suppose that the number 15 were to be added 12 times: One could set up the problem as 15 + 15 + 15 + 15 + 15..., until there were 12 additions. It is faster, however, to multiply 15 by 12 once. The multiplication sign (×) indicates that numbers are to be multiplied. The result of multiplication is called the ***product.*** Multiplication problems can be written two ways:

in a string: 15 × 12 = 180 *(product)*
or
in a column: 15
× 12
180 *(product)*

Multiplication is often useful in the automotive field. Suppose that a customer purchased four new tires. The tires cost $104 each. Rather than adding the price of each tire individually, it is easier to multiply $104 by 4.

104
× 4
416

The price for four tires would be $416.

Numbers of more than one digit used as multipliers are multiplied one digit at a time. The products for each multiplication are stacked and then added together. Suppose that the customer in the previous example purchased 41 tires at $104 each.

104
× 41
104
416
4264 *(product)*

Note that the second product (416) is shifted one column to the left. This is done because the multiplier is actually 40, not 4. To help make this clear, mentally place a 0 after the 6 in the second product (104 × 40 = 4160).

Fractions and Decimal Fractions

Fractions and decimal fractions are used to represent a portion of a whole number.

Fractions are written as two numbers, one over the other or one beside the other:

$\frac{4}{5}$ or 4/5 *(The fraction is read as "four-fifths.")*

The number below the line or after the slash is called the denominator. This number tells how many parts the whole is divided into; the number above the line or ahead of the slash tells how many parts are present in the fraction. This number is called the numerator. When reading a fraction, the top or first number is always read first; thus, read 12/32 as "twelve thirty seconds."

Decimal fractions also have a numerator and denominator. The denominator is always a multiple of 10. However, it is never written. A dot or period, called a decimal point, is used in its place. For example, 9/10 is written as 0.9 in decimal notation. The number of digits to the right of the decimal point tells what multiple of 10 the denominator is. Thus:

0.9 is 9/10 *(nine-tenths)*
0.09 is 9/100 *(nine-hundredths)*
0.009 is 9/1000 *(nine-thousandths)*
0.0009 is 9/10,000 *(nine ten-thousandths)*

Since decimal fractions are easier to work with than fractions, it is common to convert fractions to decimal fractions. This is especially true in the automotive service field. Very small measurements are given in thousandths of an inch. However, wrenches are still sized in fractions.

Decimal fractions are used for fine measurements, such as the exact size of machined engine parts. Often, the technician must use a micrometer to check a dimension, such as the diameter of a crankshaft journal or the runout on a brake rotor. Decimal fractions can be added, subtracted, multiplied, and divided in the same manner as whole numbers.

There are rules that must be remembered when working with decimal numbers. The first set of rules has to do with placement of zeros.

- A zero placed between a number and a decimal point changes the value of the number (.45 is not the same as .045).
- A zero placed to the right of a decimal number does not change the value of the number (.45 is the same as .450).
- A zero placed to the left of the decimal point does not change the value of the decimal number (.45 is the same as 0.45).

Addition and Subtraction of Decimals

The rules for addition and subtraction of decimal fractions are:

- Line up the decimal points in a column.
- The decimal point in the answer must be in the same position as the decimal point in the column.
- Since some decimal fractions will have more numbers to the right of the decimal point than others, you may fill in with zeros on the shorter numbers. This is optional.

Example:
$$\begin{array}{r} 1.5 \\ 9.356 \\ 3.62 \\ \underline{.96} \\ 15.436 \end{array} \qquad \textit{could also be written with zeros in the blanks} \qquad \begin{array}{r} 1.500 \\ 9.356 \\ 3.620 \\ \underline{0.960} \\ 15.436 \end{array}$$

Multiplication and Division of Decimals

Multiplying decimal numbers is not much different than multiplying whole numbers. The rules explain how to deal with the decimal point.

- In setting up the problem, the decimal points do not need to be aligned.
- Multiply the two numbers, ignoring the decimal points.
- Count the total number of digits (places) to the right of the decimal points of both numbers. Starting from the right-hand digit, count to the left the same number of digits in the answer. Place the decimal point to the left of the last digit counted. Dividing decimals is also similar to dividing whole numbers. Several steps are involved.
- If neither the dividend nor divisor contain decimal points, but the division does not come out even:

  Place a decimal point to the right of the last number of the dividend. Add one or more zeros after the decimal and continue dividing to the number of decimal places necessary.

For example:
$$\begin{array}{r} 7.71 \\ 7\overline{)\,54.00} \\ \underline{49} \\ 50 \\ \underline{49} \\ 10 \\ \underline{7} \\ 3 \end{array}$$

Division carried out two decimal places

- When the dividend has a decimal and the divisor does not:

  Divide as usual.

  Place a decimal point in the answer directly above the decimal point in the dividend. It will occur at the time that the division process moves past (to the right) of the decimal point.

  For example:
$$\begin{array}{r} 2.01 \\ 25\,\overline{)50.25} \\ \underline{50} \\ 02 \\ \underline{0} \\ 25 \\ \underline{25} \\ 0 \end{array}$$

- When the divisor has a decimal point:

  If the dividend does not have a decimal point, add one at the far right.

  If the dividend has a decimal point, move it one place to the right for each decimal place in the divisor. Move the decimal point in the divisor accordingly to the right. Use zeros as place holders, if necessary.

  Divide as usual.

  Place a decimal point in the answer directly above the relocated decimal point in the dividend. It will occur when the division process moves to the right past the decimal point.

  For example: $2.5\,\overline{)50.25}$
$$\begin{array}{r} 20.1 \\ 25.\,\overline{)502.5} \\ \underline{50} \\ 02 \\ \underline{0} \\ 25 \\ \underline{25} \\ 0 \end{array}$$

Workplace Skills

When working as an automotive technician, you will frequently have to take or use measurements. If your measurements are not within factory *tolerances* (acceptable ranges or limits), you know that the part requires repair, replacement, or adjustment. When working, remember that measuring tools are very delicate. Measuring tools can be damaged and thrown out of calibration simply by being dropped on the shop floor. Handle measuring tools carefully.

Summary

- As a vehicle is driven, its moving parts slowly wear out. With enough part wear, mechanical failures and performance problems result.
- Auto manufacturers give "specs," or specifications (measurements), for maximum wear limits and dimensions of specific parts.
- Our customary measuring system originated from sizes taken from parts of the human body.
- The metric (SI) measuring system uses a power of 10 for all basic units.
- A steel rule, also called scale, is frequently used to make low-precision linear (straight-line) measurements.
- A dial caliper is a sliding caliper with a dial gauge attached.
- A micrometer, nicknamed a "mike," is commonly used when making very accurate measurements.
- Never drop or overtighten a micrometer. It is very delicate and its accuracy can be thrown off easily.
- A feeler gauge is used to measure small clearances or gaps between parts.
- A dial indicator will measure part movement in thousandths of an inch (hundredths of a millimeter).
- A torque wrench measures the amount of turning force applied to a fastener (bolt or nut).
- A pressure gauge is frequently used in the auto shop to measure air and fluid pressure in various systems and components.
- Automotive technicians use mathematics during servicing and repair of vehicles.

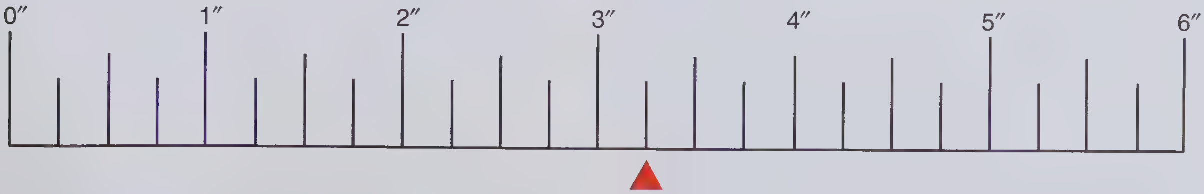
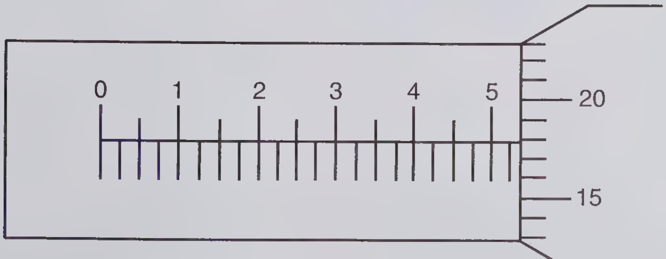
Review Questions—Chapter 6

Please do not write in this text. Place your answers on a separate sheet of paper.

1. The two measuring systems are the _____ measuring system, and the _____ measuring system.
2. Parts of the human body are used as the basis for the customary measuring system. True or False?
3. The metric system uses a power of 16 for all basic units. True or False?
4. Which of the following is *not* a metric value?
   (A) Decimeter.
   (B) Octimeter.
   (C) Millimeter.
   (D) Meter.
5. What is a measuring system conversion chart?
6. A decimal system conversion chart is used to find equal values for _____, _____, and _____.
7. Describe the four steps for reading a customary outside micrometer.
8. Describe the four steps for reading a metric outside micrometer.
9. Which of the following is *not* a special micrometer used in auto technology?
   (A) Inside micrometer.
   (B) Depth micrometer.
   (C) Width micrometer.
   (D) All of the above.
10. Describe the differences between a flat feeler gauge and a wire feeler gauge.
11. A dial indicator will measure part _____ in thousandths of an inch or _____ of a millimeter.
12. List the four basic rules for measuring with a dial indicator.
13. The three types of torque wrenches are the _____ _____, _____ _____, and _____.
14. For measuring purposes, the circle is divided into 720 degrees. True or False?
15. Explain the use of a vacuum gauge.
16. Note the inch rule below and give the measurement by full inches and fractions of an inch.
17. Give the micrometer reading for the micrometer scale shown below.
18. An automotive piston's connecting rod is 8″ long. What is the approximate length of this connecting rod in millimeters?
    (A) 42 mm.
    (B) 173.6 mm.
    (C) 203.2 mm.
    (D) 307.8 mm.
19. Which of the following instruments measures in pounds per square inch (psi)?
    (A) Pressure gauge.
    (B) Flat feeler gauge.
    (C) Depth micrometer.
    (D) Combination square.
20. When using a vacuum gauge, Technician A states that the gauge reads in inches of mercury. Technician B says that the gauge reads in kilograms per square centimeter. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.



Inch rule for question 16.



Micrometer reading for question 17.

ASE-Type Questions

1. "Specs" are:
   (A) *dimensions of parts.*
   (B) *maximum wear limits of parts.*
   (C) *measurements of specific parts.*
   (D) *All of the above.*
2. Technician A says the customary measuring system originated from sizes taken from parts of the human body. Technician B says customary units were derived from the landscape. Who is right?
   (A) *A only.*
   (B) *B only.*
   (C) *Both A and B.*
   (D) *Neither A nor B.*
3. Which of the following is used to make low-precision linear measurements?
   (A) *Steel rule.*
   (B) *Pocket scale.*
   (C) *Inside caliper.*
   (D) *Combination square.*
4. Which of the following measuring devices has an attached gauge that makes measurements easier to read?
   (A) *Divider.*
   (B) *Dial caliper.*
   (C) *Sliding caliper.*
   (D) *Combination square.*
5. Volume can be measured in each of these *except:*
   (A) *liters.*
   (B) *quarts.*
   (C) *kilopascals.*
   (D) *cubic inches.*
6. When using a decimal conversion chart, fractions are only accurate to about:
   (A) *1/16 of an inch.*
   (B) *1/64 of an inch.*
   (C) *1 centimeter.*
   (D) *0.025 millimeters.*
7. Each number on a customary micrometer equals:
   (A) *0.100″.*
   (B) *0.200″.*
   (C) *0.300″.*
   (D) *0.400″.*
8. Which of the following is *not* a good rule to remember when using a micrometer?
   (A) *Never drop or overtighten a micrometer.*
   (B) *Hold the micrometer squarely with the work.*
   (C) *Grasp frame with fingers and turn with palm.*
   (D) *Put a little oil on a micrometer when in storage.*
9. This type of gauge is used to measure the distance between unparallel or curved surfaces:
   (A) *flat feeler gauge.*
   (B) *wire feeler gauge.*
   (C) *telescoping gauge.*
   (D) *spring gauge.*
10. A dial indicator measures part movement in:
    (A) *kilopascals.*
    (B) *millimeters.*
    (C) *hundredths of an inch.*
    (D) *thousandths of an inch.*

Activities—Chapter 6

1. Demonstrate the proper reading of a dial indicator.
2. Use the micrometer to measure a part supplied by your instructor.
3. Demonstrate to the class the use of a feeler gauge.

7

Using Service Information

After studying this chapter, you will be able to:

- Describe the different types of service manuals.
- Find and use the service manual index and contents sections.
- Explain the different kinds of information and illustrations used in a service manual.
- Describe the three basic types of troubleshooting charts found in service manuals.
- Explain how to use computer-based service information.
- Correctly answer ASE certification test questions concerning service information.

Vehicles contain thousands of parts. Many of these parts are assembled to close tolerances (exacting standards) and require precise assembly and adjustment. Sometimes a technician needs specific technical information to properly repair a vehicle. In these cases, the technician must refer to a service manual, CD-ROM, computer network, or other service information.

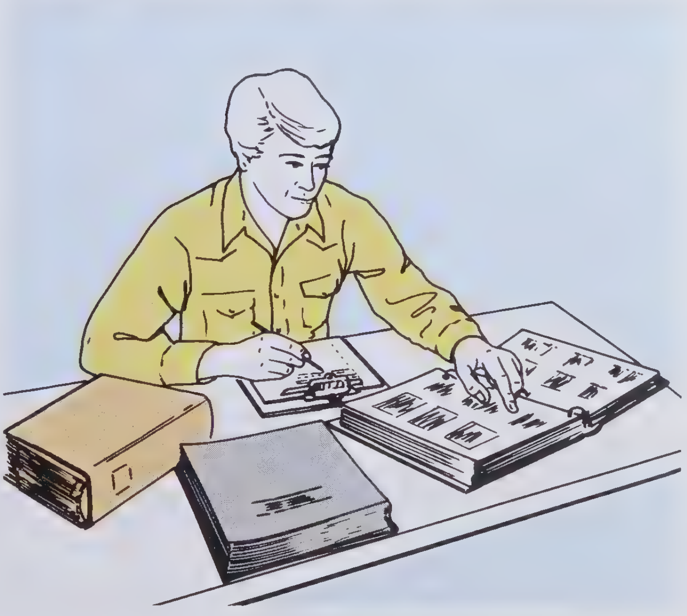


Figure 7-1. Service manuals will answer almost any repair question. The manuals are essential reference tools of automotive technicians. (Deere & Co.)

Service Manuals

Service manuals, also called ***shop manuals,*** are books with detailed information on how to repair a vehicle. They have step-by-step procedures, specifications, diagrams, part illustrations, and other data for each vehicle model. Every service facility normally has a set of service manuals. They help technicians with difficult repairs. Refer to **Figure 7-1.**

Service manuals are written in very concise, technical language. They are designed to be used by well-trained technicians. A service manual is one of a technician's *most important tools.*

Service Manual Types

There are various types of service manuals. These include manufacturer's manuals, specialized manuals, and general repair manuals. It is important to understand the differences between each type.

Manufacturer's manuals, also called ***factory manuals,*** are published by a vehicle's manufacturer. Each manual covers a specific vehicle produced by the manufacturer during a given model year.

Specialized manuals cover only specific repair areas. They usually come in several volumes, each covering one section of the vehicle. One may cover engines and another body components or electrical systems. Specialized manuals are published by vehicle manufacturers or aftermarket companies. Aftermarket companies are suppliers other than a vehicle manufacturer.

General repair manuals are published by companies other than the major vehicle makers. Some of these companies include Mitchell Manuals, Motor Manuals, and

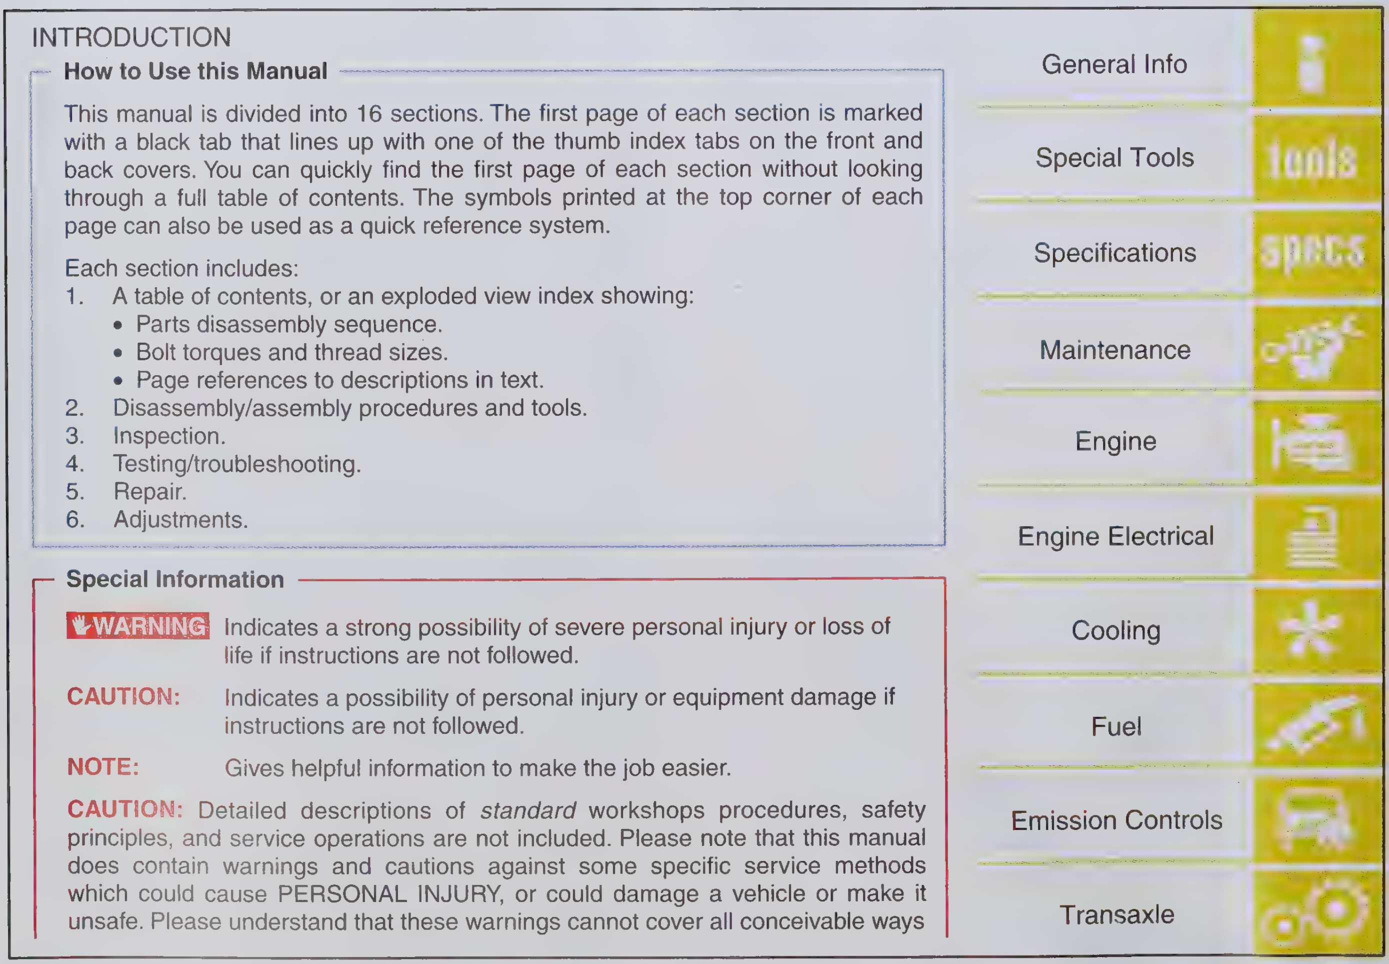
Chilton Manuals. General repair manuals are similar to manufacturer's manuals, but they are usually *not* as detailed. They may include data on all American cars produced over a period of several years. Other general repair manuals only cover foreign cars, light trucks, or large trucks. It is often too costly for a service facility to buy service manuals from every vehicle manufacturer. Instead, they may buy two or three general repair manuals for all types of vehicles. These manuals summarize the most important and most needed information.

Service Manual Sections

A service manual is divided into sections, such as general information, engine, transmission, and electrical. See **Figure 7-2.** To effectively use a service manual, you need to understand these sections and how they are organized.

The ***general information section*** of a service manual helps you with a vehicle's identification, basic maintenance, lubrication, and other general subjects. An important topic in this section is the ***vehicle identification number (VIN).*** The VIN provides data about the car. It is commonly used when ordering parts. The number, which is usually found on a plate located on the vehicle's dashboard, contains a code. The manual explains what each part of this number code means. Look at **Figure 7-3.** The VIN tells you engine type, transmission type, and other useful information.

The ***repair sections*** of a service manual cover the vehicle's major systems. These sections explain how to recognize and diagnose problems and inspect, test, and repair each system. One page may describe how to remove the engine. Another page might explain how to disassemble the engine. Specifications such as bolt tightening limits, capacities, clearances, and operating temperatures are given in the repair sections. These specifications are commonly used during service and repair operations. The repair section also refers to special tools that are needed for a limited number of repair tasks. These tools may be pictured at the end of the manual section. Refer to **Figure 7-4.**



INTRODUCTION

How to Use this Manual

This manual is divided into 16 sections. The first page of each section is marked with a black tab that lines up with one of the thumb index tabs on the front and back covers. You can quickly find the first page of each section without looking through a full table of contents. The symbols printed at the top corner of each page can also be used as a quick reference system.

Each section includes:

1. A table of contents, or an exploded view index showing:
    - Parts disassembly sequence.
    - Bolt torques and thread sizes.
    - Page references to descriptions in text.
2. Disassembly/assembly procedures and tools.
3. Inspection.
4. Testing/troubleshooting.
5. Repair.
6. Adjustments.

Special Information

WARNING Indicates a strong possibility of severe personal injury or loss of life if instructions are not followed.

CAUTION: Indicates a possibility of personal injury or equipment damage if instructions are not followed.

NOTE: Gives helpful information to make the job easier.

CAUTION: Detailed descriptions of *standard* workshops procedures, safety principles, and service operations are not included. Please note that this manual does contain warnings and cautions against some specific service methods which could cause PERSONAL INJURY, or could damage a vehicle or make it unsafe. Please understand that these warnings cannot cover all conceivable ways

Service Manual Illustrations

Various types of ***service illustrations*** are used to supplement the written information in a service manual. Some show how to measure part wear, while others show how to install a part. Others show an exploded, or disassembled, view of parts. When using a service manual, you will find the illustrations essential for a full understanding of the procedures and specifications. They may show you what parts look like, how they fit together, where leaks might occur, or how a part works. **Figure 7-5** shows some common types of service manual illustrations.

Tool Number & Description	Illustration
49-0813-310 Centering tool, clutch disc	49-0500-330 Installer, transition bearing	49-0259-440 Turning holder, mainshaft	49-0862-350 Guide, shift fork assembly	
Figure 7-4. The service manual will explain any special tool numbers. Note these special tools for clutch and transmission repairs. (Mazda)

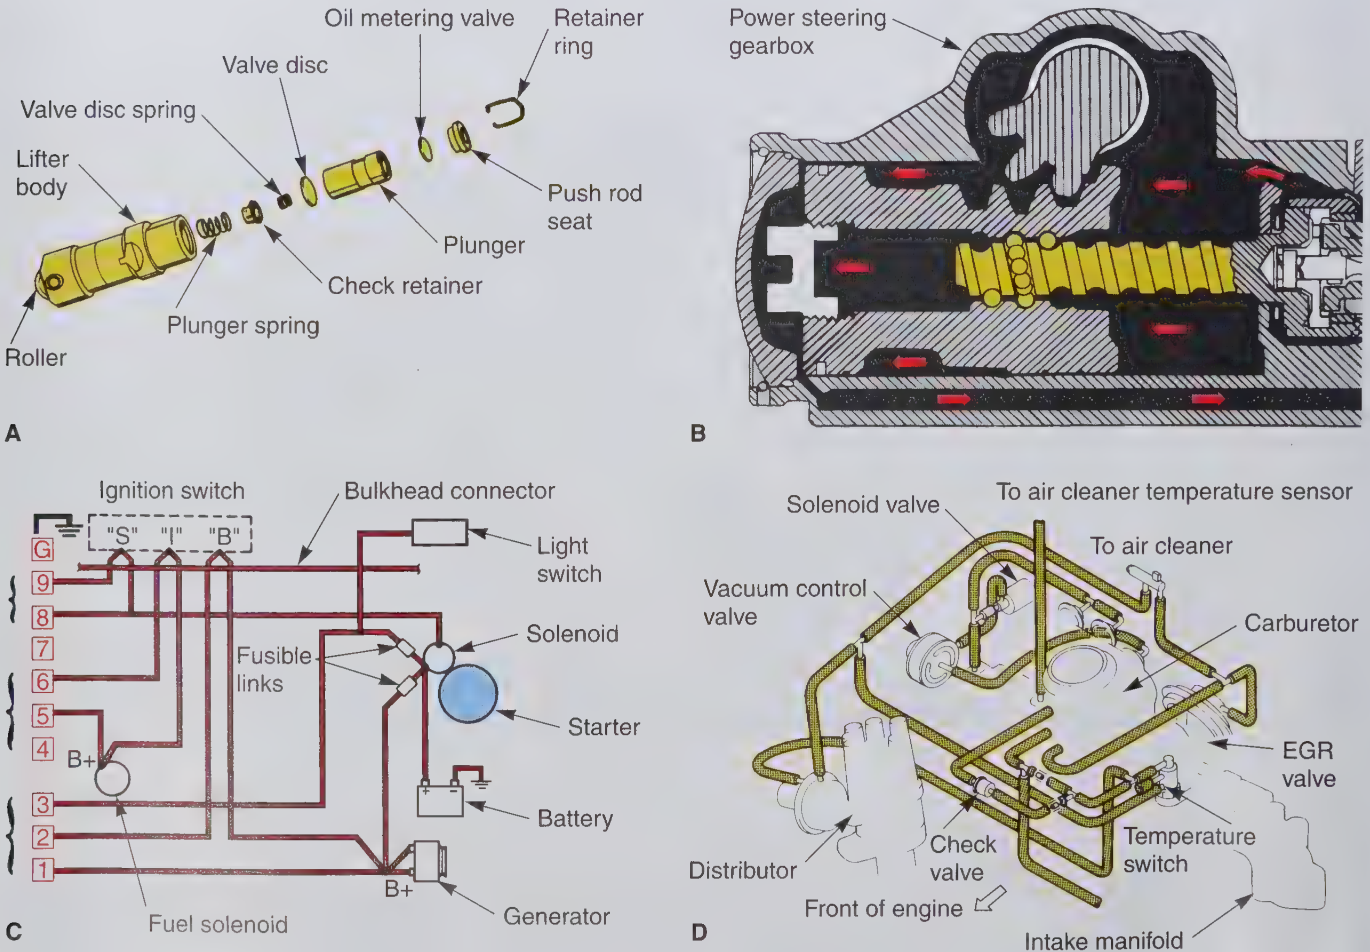
Service Manual Diagrams

Diagrams are drawings used when working with electrical circuits, vacuum hoses, and hydraulic circuits. They represent how wires, hoses, passages, and parts connect together. ***Wiring diagrams*** show how the wiring connects to the electrical components. See **Figure 7-5C.** This subject is covered later in the text.

Vacuum diagrams help the technician determine how vacuum hoses connect to the engine and vacuum-operated devices, **Figure 7-5D.** ***Hydraulic diagrams*** show how a fluid, usually oil, flows in a circuit or part. They are helpful in understanding how a component operates or how to troubleshoot problems. Hydraulic diagrams are commonly given for automatic transmissions and power steering systems.

Service Manual Abbreviations

Abbreviations are letters that stand for an entire word. They are often used in service manuals. Sometimes,



Oil metering valve

Figure 7-6. SAE-recommended abbreviations.

Diagnostic Charts

Diagnostic charts, or ***troubleshooting charts,*** give steps for finding and correcting problems in an automobile. These steps may include inspection, testing, measurement, and repair. If the source of the problem is hard to find, a diagnostic chart should be used. It will guide you to the most common causes of specific problems. There are four basic types of diagnostic charts. These are tree, block, illustrated, and component location charts.

A ***tree diagnosis chart*** provides a logical sequence for what should be inspected or tested when trying to solve a repair problem, **Figure 7-7.** For instance, if a horn will not work, the top of the tree chart may tell you to check the horn's fuse. Then, if the fuse is good, it may have you measure the voltage going to the horn. You can work your way down the "tree" until the problem is fixed.

A ***block diagnosis chart*** lists conditions, causes, and corrections in columns, **Figure 7-8.** The most common cause is the top listing. For example, if an engine overheats, loss of coolant appears at the top of the "causes" column. Check the coolant level. If this is the problem, fill the radiator and check for leaks. If the coolant level is OK, go to the next listing.

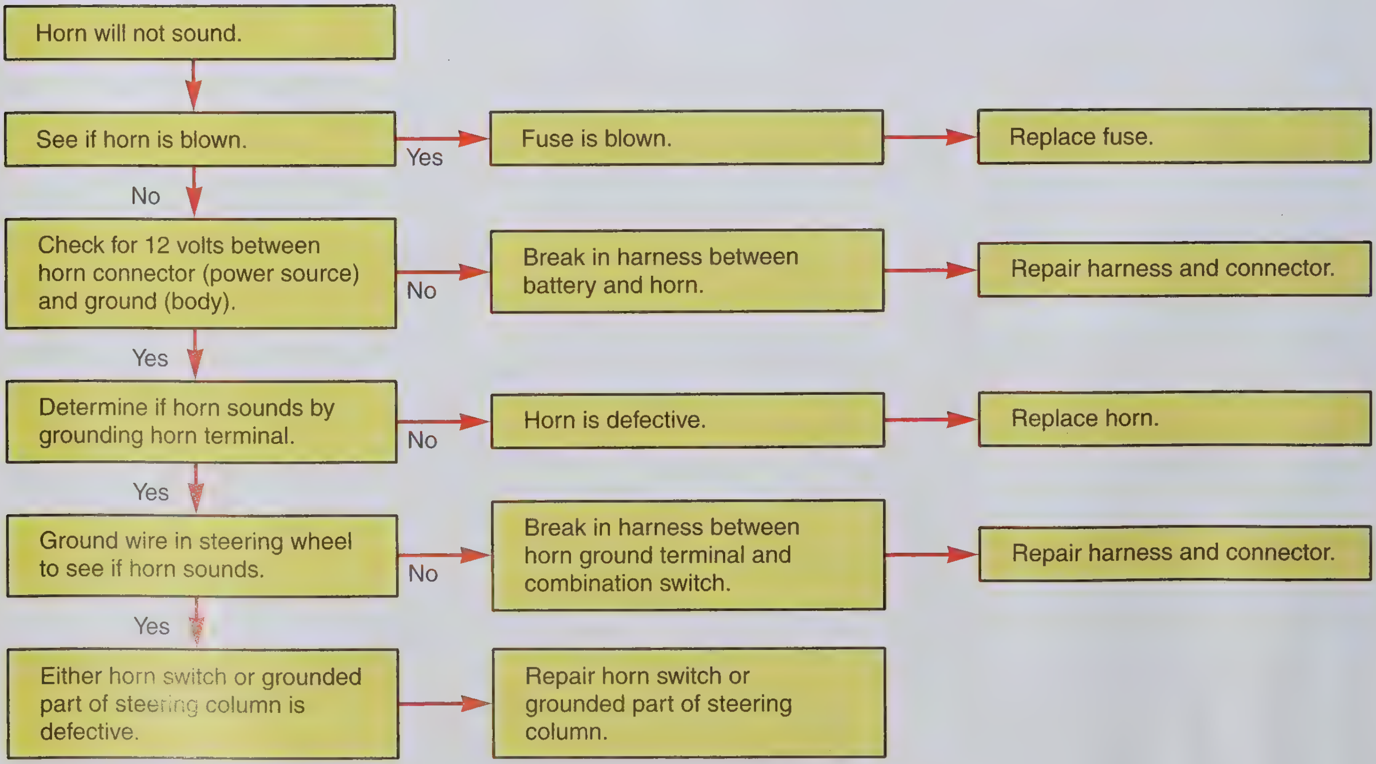
An ***illustrated diagnosis chart*** uses pictures, symbols, and words to guide the technician through a sequence of tests. This type of troubleshooting chart is illustrated in **Figure 7-9.** If an engine oil pressure gauge shows low oil pressure, for example, the chart shows you exactly what to do, step by step, until the problem is corrected. This type of diagnosis chart not only tells you what to do, but it shows you how to do it.

A ***component location chart*** shows where various parts are located on the vehicle. This type of chart is often used for the engine compartment. The chart helps locate the numerous sensors, relays, fuses, and other components housed in this area. See **Figure 7-10.**

Using a Service Manual

To use a service manual, follow these basic steps:

1. Locate the proper service manual. Some manuals come in sets or volumes that cover different repair areas. Others cover all subjects and all car makes. If you are working on engines, find the manual that gives the most information for the type of engine being serviced.
2. Turn to the table of contents or the index to quickly find the needed information. *Never* thumb through a manual looking for a subject.
3. Use the page listings given at the beginning of each repair section. Most manuals have a small



Horn will not sound.
See if horn is blown.
Yes
Fuse is blown.
Replace fuse.
No
Check for 12 volts between horn connector (power source) and ground (body).
No
Break in harness between battery and horn.
Repair harness and connector.
Yes
Determine if horn sounds by grounding horn terminal.
No
Horn is defective.
Replace horn.
Yes
Ground wire in steering wheel to see if horn sounds.
No
Break in harness between horn ground terminal and combination switch.
Repair harness and connector.
Yes
Either horn switch or grounded part of steering column is defective.
Repair horn switch or grounded part of steering column.

Figure 7-7. A tree diagnosis chart starts at the top and guides you through repair operations.

Condition	Possible Cause	Correction
• Loss of coolant.	• Pressure cap and gasket.	• Inspect, wash gasket, and test. Replace only if cap will not hold pressure test specifications.
	• Exhaust leakage.	• Pressure test system. • Inspect hose, hose connections, radiator, edges of cooling system gaskets, core plugs, drain plugs, transmission oil cooler lines, water pump, heater system components. Repair or replace as required.
	• Internal leakage.	• Check for obvious restrictions. • Check torque of head bolts. Retorque if necessary. • Disassemble engine as necessary— check for cracked intake manifold, blown head gaskets, warped head or block gasket surfaces, cracked cylinder head, or engine block.
• Engine overheats.	• Low coolant level.	• Fill as required. Check for coolant loss.
	• Loose fan belt.	• Adjust.
	• Pressure cap.	• Test. Replace if necessary.
	• Radiator or A/C condenser obstruction.	• Remove bugs and leaves.
	• Closed thermostat.	• Test. Replace if necessary.
	• Fan drive clutch.	• Test. Replace if necessary.
	• Ignition.	• Check timing and advance. Adjust as required.
	• Temperature gauge or cold light.	• Check electrical circuits and repair as required.
	• Engine.	• Check water pump and block for blockage.
	• Exhaust system.	• Check for restrictions.
• Engine fails to reach normal operating temperature.	• Thermostat stuck open.	• Test. Replace if necessary.
	• Temperature gauge or cold light inoperative.	• Check electrical circuits and repair as required. Refer to electrical section.

Figure 7-8. A block diagnosis chart lists conditions, causes, and corrections in columns. Read to the right to match a condition with possible causes and corrections. (Ford)

table of contents at the beginning of each section.

4. Read the procedures carefully. A service manual gives highly detailed instructions. You must *not* overlook any step or the repair may fail.
5. Study the manual illustrations closely. The pictures in a service manual contain essential information. They cover special tools, procedures, torque values, and other data essential to the repair.

Tech Tip!

Service manual layouts and features vary. The best way to learn their use is to practice finding information in them. For example, on your lunch hour, look up specific service information in several types of manuals. Compare the organization and differences in each manual. This will help you find data more quickly when on the job.

Service Publications

A service manual is just one kind of book that contains technical information on a vehicle. Other types, called ***service publications,*** include owner's manuals, flat rate manuals, and technical bulletins.

Owner's Manual

An ***owner's manual*** is a small booklet given to the purchaser of a new vehicle. It contains basic information on starting the engine, maintaining the car, and operating vehicle accessories.

Flat Rate Manual

A ***flat rate manual*** is used to calculate how much labor to charge the customer for a repair. It contains an estimate of how much time a specific repair should take. This time can then be multiplied by the shop's hourly labor rate to find the labor charge in dollars. Using the flat rate manual, you will be able to give the customer a cost estimate before beginning the actual repair.

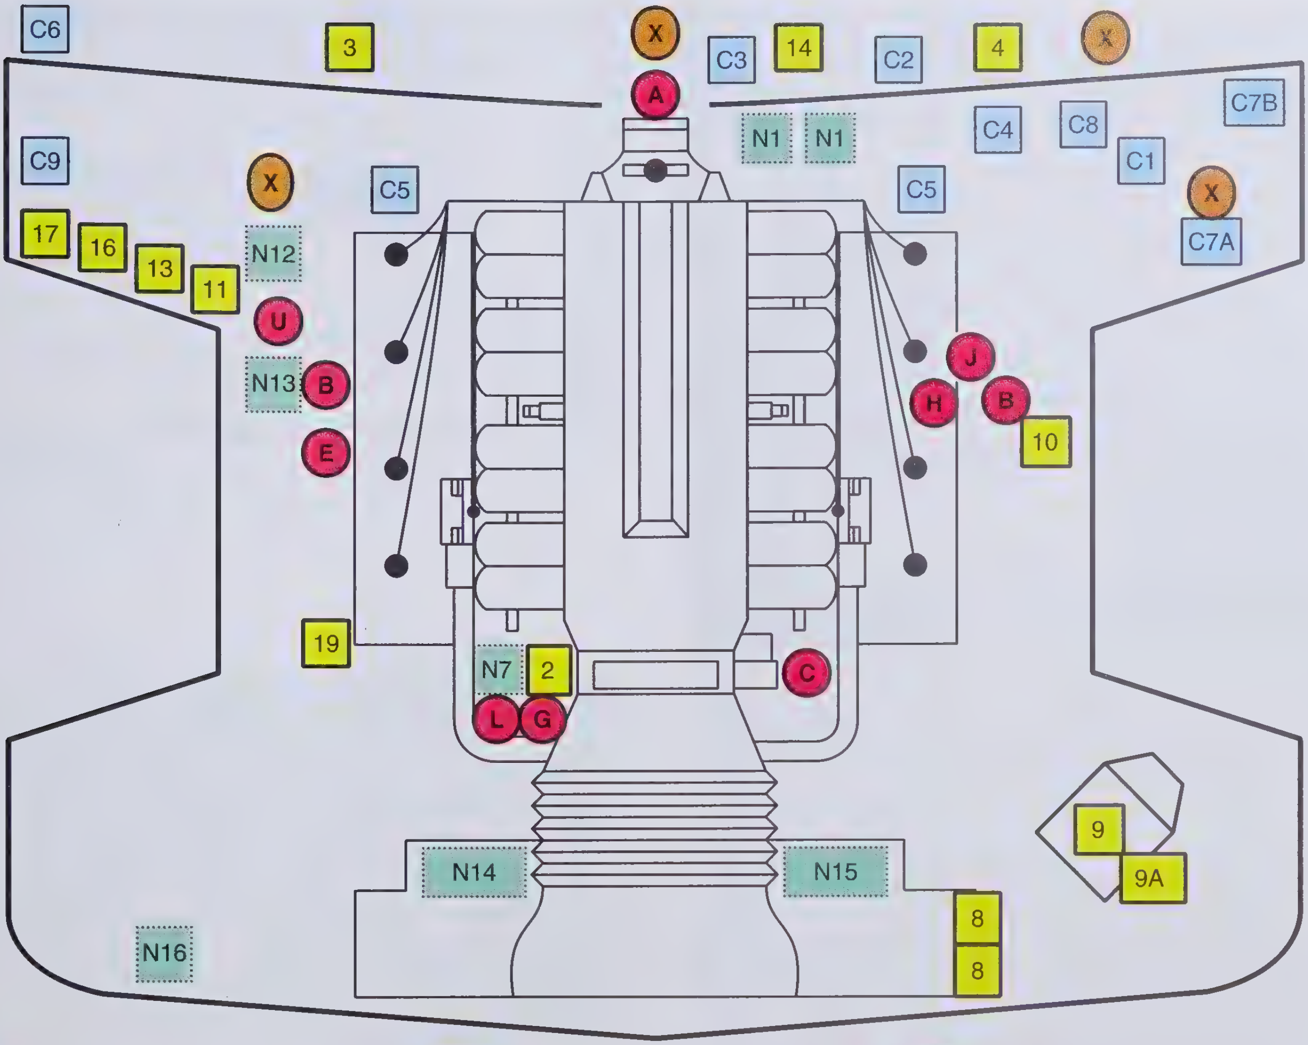
Technical Bulletins

Technical bulletins help the technician stay up-to-date with recent technical changes, repair problems, and other service-related information. Usually only a few pages long, these publications are mailed to the service manager, who passes them along to the technicians. Technical bulletins are published by auto manufacturers and equipment suppliers.

Tech Tip!
Technical bulletins often describe common troubles with certain makes of vehicles. This allows you to check these common problems first.

Computerized Service Data

Computerized service data is information stored or retrieved electronically using a personal computer, **Figure 7-11.** Information may be stored on a floppy disk, hard drive, CD-ROM, or a computer network. A computer can find and retrieve this information quicker than a technician using a book. Modern repair shops are using more and more computer-based service data.



🟦 Computer Harness

C1	Engine Control Module (ECM)
C2	Data Link Connector (DLC)
C3	Malfunction Indicator Lamp (MIL)
C4	Electronic Ignition diagnostic connector
C5	ECM harness grounds
C6	I/P fuse panel
C7A	Underhood fuse block
C7B	Underhood fuse block
C8	Fuel pump test connector
C9	TP sensor interface module

🟩 Not ECM Connected

N1	Crankcase ventilation valve
N7	Oil pressure sensor gauge
N12	A/C pressure cycling switch
N13	A/C high pressure cycling switch
N14	Secondary cooling fan (FAN 2)
N15	Primary cooling fan (FAN 1)
N16	Secondary air inlet valve electric vacuum pump

🟨 Controlled Devices

2	Idle Air Control (IAC) valve
3	Fuel Pump (FP) relay (primary)
4	Fuel Pump (FP) relay (secondary)
8	Cooling fan relay(s)
9	Secondary Air Injection (AIR) pump
9A	Air pump relay
10	Air bypass valve
11	2nd & 3rd gear block out solenoid
13	A/C clutch relay
14	2nd & 3rd gear block out solenoid
16	Secondary SFI control module #1
17	Secondary SFI control module #2
19	Linear EGR valve

● Information Sensor

A	Manifold Absolute Pressure (MAP) sensor
B	Heated Oxygen Sensor (HO2S)
C	Throttle Position (TP) sensor
E	Crankshaft Position sensor
F	Vehicle Speed Sensor (VSS) (mounted on transmission, not shown)
G	Intake Air Temperature (IAT) sensor
H	Camshaft Position Sensor
J	Knock Sensor (KS)
L	Engine oil temperature sensor
U	A/C cooling fan switch

Ⓧ SIR System Components. Refer to section 9J of the Service Manual, for "Cautions" and information on SIR System Components.

Figure 7-10. Study the location of the parts shown in a component location chart. The service manual will often give this type of chart for the exact make and model car being serviced. (Chevrolet)

Figure 7-11. A computer is now a commonly used tool of many technicians. It can help with everything from ordering parts to troubleshooting hard-to-find problems. (OTC)

A floppy disk is an inexpensive way to hold computer information. However, the storage capacity is limited.

A ***CD-ROM,*** or ***compact disc,*** is a computer storage device with tremendous capacity for holding large amounts of data. One CD can hold the information from a whole set of service manuals. Many shops now keep their service and reference information on CDs.

The ***Internet*** is a computer network that allows you to communicate with other computers all over the world.

A ***modem*** is connected to the computer and used to access the Internet through a phone line or cable. Various Internet sites are available for finding common vehicle troubles, manufacturer recalls, and new tools. See **Figure 7-12**. On-line networks allow a service facility to find service information that is not available in the manuals or electronic media they have on hand.

Service facility computer systems can also store information on various items, such as:

- Repair procedures.
- Repair illustrations.
- Part prices.
- Labor times.
- Safety rules.
- Troubleshooting charts.
- Trouble code charts.

International Automotive Technicians' Network

iATN Mission of Excellence

"To promote the continued growth, success and image of the professional automotive technician by providing a forum for the exchange of knowledge and the promotion of education, professionalism, and integrity."

iATN Member Logon

Welcome to the largest network of automotive technicians in the world. The International Automotive Technicians' Network is a group of 38,779 professional automotive technicians from 122 countries. The automotive professionals of this group exchange technical knowledge and information with other members from around the globe, sharing 785,137 years of experience!

iATN Shop Finder

Joining iATN

Figure 7-12. The Internet can be a valuable source of information. Some Internet sites, such as the International Automotive Technician's Network, allow technicians to share their technical knowledge. (iATN)

Workplace Skills

In the past, printed service manuals provided most of the repair information used by the automotive technicians. Today, computer-based service information is replacing printed information. One advantage of computer-based service information is the ability to conduct a keyword search. You can instantly find and display repair procedures, illustrations, diagnosis charts, and other important information about the vehicle being serviced.

Summary

- Service manuals are books with detailed information on how to repair a vehicle. They have step-by-step procedures, specifications, diagrams, part illustrations, and other data for each model of vehicle.
- Manufacturer's manuals are published by vehicle manufacturers.
- A service manual is divided into sections, such as general information, engine, transmission, and electrical.
- The VIN is a number code that indicates engine type, transmission type, and other useful information.
- Various types of service illustrations are used to supplement the written information in a service manual.

- Diagrams are drawings used when working with electrical circuits, vacuum hoses, and hydraulic circuits.
- Abbreviations are letters that stand for entire words.
- A flat rate manual is used to calculate how much labor to charge the customer for a repair.
- Computerized service data is information stored or retrieved using a personal computer instead of a book or publication.

Review Questions—Chapter 7

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What is a service manual?
2. Which of the following is *not* a service manual containing information on car repairs?
   (A) Manufacturer's manual.
   (B) Owner's manual.
   (C) General repair manual.
   (D) All of the above.
3. Explain the purpose of the following.
   (A) Wiring diagrams.
   (B) Vacuum diagrams.
   (C) Hydraulic diagrams.
4. List ten common abbreviations and explain them.
5. The following is *not* a common type of diagnostic chart.
   (A) Track diagnosis chart.
   (B) Tree diagnosis chart.
   (C) Block diagnosis chart.
   (D) Illustrated diagnosis chart.
6. Write the five basic steps for using a service manual.
7. A _____ _____ manual is used to calculate how much labor to charge for a repair.
8. _____ _____ help the technician stay up-to-date with recent technical changes, repair problems, and other service related information.
9. Why has computerized service data become more common?
10. The computer network that allows you to communicate with computers all over the world is called the _____.
    (A) Modem
    (B) CD-ROM
    (C) Internet
    (D) None of the above

ASE-Type Questions

1. Each of the following is a type of service manual *except:*
   (A) general repair manuals.
   (B) owner's manuals.
   (C) factory manuals.
   (D) specialized manuals.
2. Technician A says VIN information is generally found in the repair section of a service manual. Technician B says VIN information is generally located in the general information section of a service manual. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. A technician who is having trouble finding the cause of a vehicle problem should refer to the following first.
   (A) Service bulletin.
   (B) Troubleshooting chart.
   (C) Spec sheet.
   (D) Repair procedures.
4. Which of the following should be used when calculating the cost of a repair?
   (A) Troubleshooting chart.
   (B) Service bulletin.
   (C) Flat rate manual.
   (D) Cold rate manual.

5. Technician A says technical bulletins describe common problems encountered on specific vehicles. Technician B says technical bulletins are often published by independent repair facilities. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

Activities—Chapter 7

1. Obtain a flat rate manual and a parts catalog from your instructor and prepare a bill for replacement of a fuel pump on a vehicle of your choice. Check the manual for the amount of labor involved. Then, consult the parts catalog for the cost of the part. Add up the costs plus the state tax for your state. (Figure labor cost at $48/hour.)
2. Using a service manual, demonstrate to your class how to find the procedure for removal and replacement of a part chosen by your instructor.

8 Basic Electricity and Electronics

After studying this chapter, you will be able to:

- Explain the principles of electricity.
- Describe the action of basic electric circuits.
- Compare voltage, current, and resistance.
- Describe the principles of magnetism and magnetic fields.
- Identify basic electric and electronic terms and components.
- Explain different kinds of automotive wiring.
- Perform fundamental electrical tests.
- Correctly answer ASE certification test questions that require a basic understanding of electricity and electronics.

Almost every system in a modern vehicle uses some type of electric or electronic part, or ***component.*** Electronic ignition systems, electronic fuel injection, computerized engine management systems, anti-lock brakes, and other advanced systems require technicians skilled in electricity and electronics. Even specialized technicians need this background to fix today's vehicles. This chapter covers the most important aspects of automotive electricity and electronics.

Electricity

Everything is made from fewer than 100 types of atoms. These atoms can be gold, carbon, lead, hydrogen, oxygen, or other elements. You are made of atoms. This book is made of atoms, so are your chair, your desk, and air—everything!

An ***atom*** basically consists of small particles called protons, neutrons, and electrons. Negatively charged ***electrons*** circle around a center of neutrons and positively charged ***protons.*** See **Figure 8-1.** The makeup of atoms varies in different substances or elements.

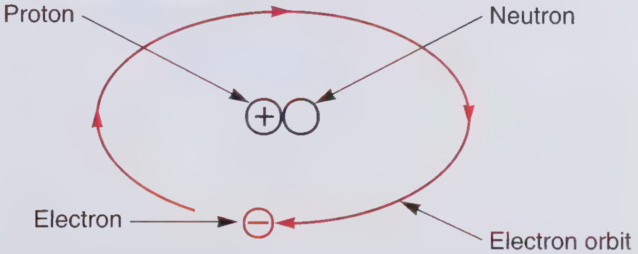

Figure 8-1. Atoms are made up of electrons, protons, and neutrons. Electrons are negatively charged. Protons are positively charged. Electricity is the movement of electrons from atom to atom.

Electricity is the movement of electrons from atom to atom. Some substances have atoms that allow electrical flow; others do not. ***Conductors,*** such as wires and other metal objects, have atoms that allow the flow of electricity. The atoms contain free electrons. ***Free electrons*** are extra electrons in the orbit of the atom that are not locked to protons.

Insulators, such as plastic, rubber, and ceramic, resist the flow of electricity. They do *not* contain free electrons. They resist the flow of electricity. Wire conductors are usually covered with plastic or rubber as an insulating material.

The maximum number of electrons in the atom's ***valence,*** or outer, band is eight. An atom with eight valence electrons is normally a good insulator. Since the valence band is filled, it is in a state of equilibrium and is reluctant to give or take an electron from the valence band of a neighboring atom. Atoms with one to three electrons in their valence band are usually good conductors. These atoms contribute electrons to, and receive electrons from, neighboring atoms. Metals such as gold, silver, and copper have a single electron in their valence band and are excellent conductors.

Current, Voltage, and Resistance

The three basic elements of electricity are current, voltage, and resistance. Current is measured in amps. Voltage is measured in volts. Resistance is measured in ohms. See **Figure 8-2.**

Current is the *flow* of electrons through a conductor. Just as water flows through a garden hose, electrons flow through a wire in a circuit. When current flows through a lightbulb, the electrons rub against the atoms in the bulb filament. This produces "electrical friction." The friction heats the filament, making it glow. Current is abbreviated ***I.***

Two theories have been used to explain how current flows through a circuit: the conventional theory and the electron theory. The ***conventional theory*** states that current flows from positive to negative. The ***electron theory,*** on the other hand, states that current flows from negative to positive. The electron theory is more widely accepted than the conventional theory. Therefore, it will be used in this text.

Voltage is the force, or *electrical pressure,* that causes electron flow. This is similar to how water pressure causes water to squirt out the end of a garden hose. An increase in voltage causes an increase in current. A decrease in voltage causes a decrease in current. Automobiles normally use a 12V electrical system. Voltage is abbreviated ***V*** or ***E.***

Resistance is the *opposition* to current flow. Resistance is needed to control the flow of current in a circuit. Just as the on/off valve on a garden hose can be opened or closed to control water flow, circuit resistance can be increased or decreased to control the flow of electricity. High resistance reduces current. Low resistance increases current. Resistance is abbreviated ***R.***

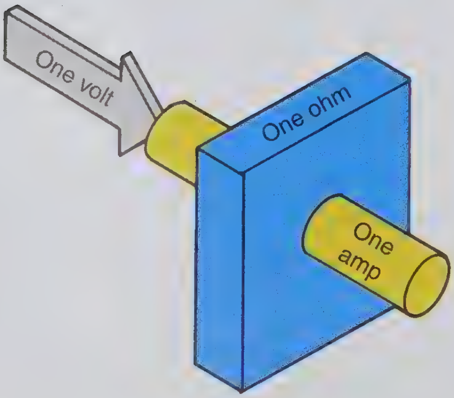

Figure 8-2. Voltage is a pressure, or pushing force. Current is the flow of electrons. Resistance opposes current flow. One volt can push one amp of current through one ohm of resistance.

Types of Circuits

Figure 8-3 shows a simple circuit. A simple circuit consists of:

- A ***power source,*** such as a battery, alternator, or generator, which supplies electricity for circuit.
- A ***load,*** which is an electrical device that uses electricity.
- ***Conductors,*** such as wires or metal parts, that carry current between power source and load.

The power source feeds electricity to the conductors and load. The conductors carry the electricity out to the load and back to the source. The load changes the electricity into another form of energy, such as light, heat, or movement.

A ***series circuit*** has more than one load connected in a single electrical path, **Figure 8-4A.** For example, inexpensive Christmas tree lights are often wired in series. With only one electrical path, if one bulb burns out, all

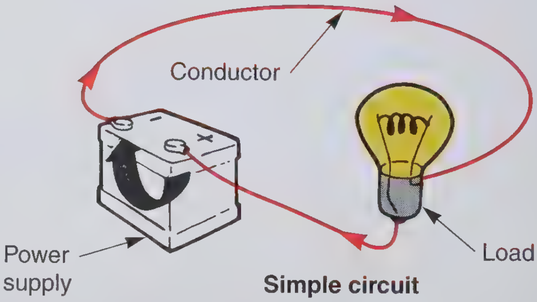

Figure 8-3. A simple electric circuit consists of a power source, a load, and a conductor. (British Leyland)

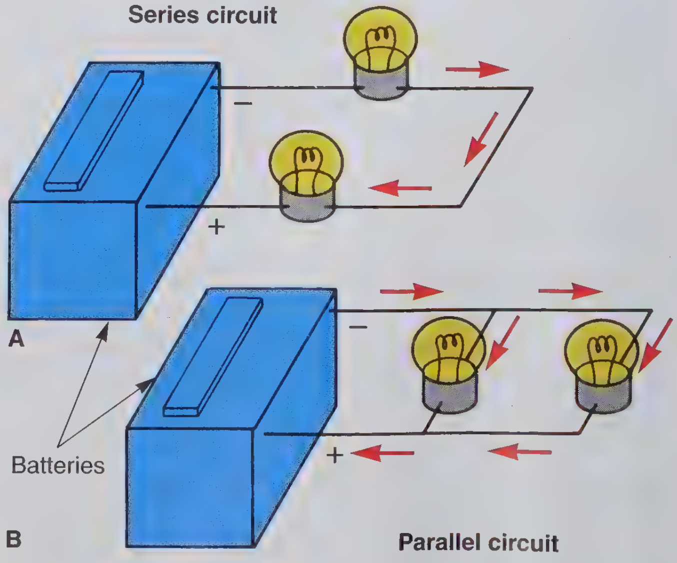

Figure 8-4. A—Series circuit only has one path for current. B—Parallel circuit has a separate path for each load.

the bulbs stop glowing. The circuit path is open, or broken, and current stops.

A ***parallel circuit*** has more than one electrical path, **Figure 8-4B.** When Christmas tree lights are wired in parallel, one bulb can burn out without affecting the others. The other bulbs have their own leg, or path, to receive current. A ***series-parallel circuit*** contains both a series circuit and a parallel circuit.

In a ***one-wire circuit,*** or ***frame-ground circuit,*** the vehicle's frame or body serves as an electrical conductor, **Figure 8-5.** A cable is used to connect the negative battery terminal to the frame. Insulated wires are used to connect the frame to the load's ground wire and the positive battery terminal to the load's hot wire. Current from the negative battery terminal travels through the vehicle's frame. From the frame, current travels through the load and into the positive battery terminal.

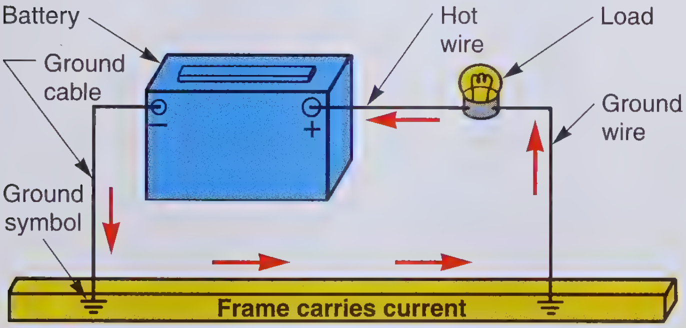

Figure 8-5. Automobile wiring commonly uses a frame ground. Metal parts of the vehicle carry current in the circuit. This reduces the number of wires needed.

Ohm's Law

Ohm's law is a simple formula for calculating circuit voltage, current, or resistance when two of the three values are known. This is illustrated in **Figure 8-6.** If you know, for example, that a circuit has 12 volts applied and a current flow of 6 amps, Ohm's law can be used to find circuit resistance. Simply plug the known values into the correct formula.

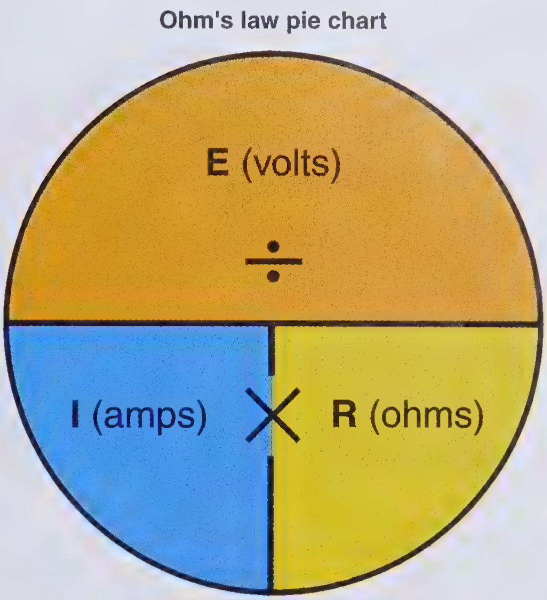
Resistance = voltage divided by current

$$R = \frac{12 \text{ Volts}}{6 \text{ amps}}$$

R = 2 ohms

Magnetic Field

You are probably familiar with magnetism from "playing with" a permanent magnet. A permanent magnet produces an invisible ***magnetic field*** that attracts ferrous, or iron-containing, objects.



E (volts) = I × R
I (amps) = E ÷ R
R (ohms) = E ÷ I

Figure 8-6. Ohm's law pie chart. Use your finger to cover the unknown value. This will show you the Ohm's law formula.

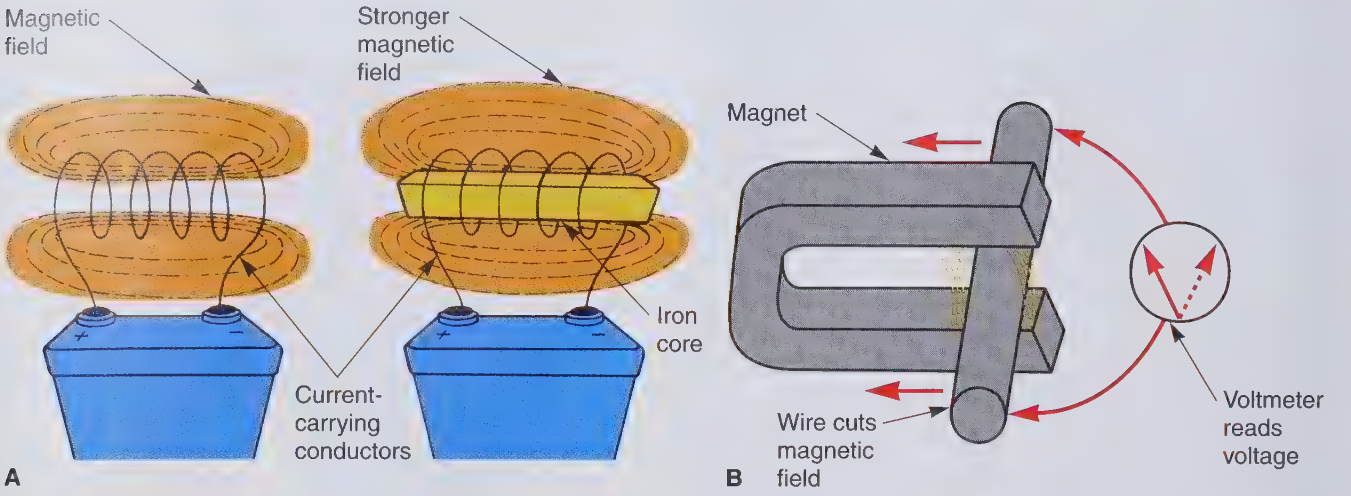
A magnetic field can also be created using electricity, **Figure 8-7A.** A long piece of wire can be wound into a coil. The ends of the wire can be connected to a battery or other source. Then, when current passes through the wire, a magnetic field is produced. To make the field, or lines of force, stronger, a soft iron bar can be inserted into the center of the coil. The iron core will become magnetized, making an electromagnet.

Magnetism can also create electricity. If a wire passes through a magnetic field, an electric current will be generated in the wire. The wire cutting the lines of force causes a tiny amount of electricity to flow through the wire. Look at **Figure 8-7B.** This action is called ***induction.***

Many automotive components use the characteristics of magnetism and magnetic fields. Electronic fuel injection, electric motors, relays, ignition systems, and on-board control modules are just a few examples.

Electrical Terms and Components

There are several electrical terms and components that auto technicians must know. Some of the most important ones are discussed here.



Magnetic field
Stronger magnetic field
Iron core
Current-carrying conductors
A
Magnet
Wire cuts magnetic field
Voltmeter reads voltage
B

Figure 8-7. A—When current flows through a wire, a magnetic field forms around the wire. The wire can be wound into a coil to strengthen the field. An iron core strengthens the field even more. B—A magnetic field can be used to produce electricity. When a wire is moved through a magnet's field, current is induced in the wire. (Deere & Co.)

A ***switch*** allows an electric circuit to be turned on or off. When the switch is ***closed,*** or on, the circuit is complete and operates. When the switch is ***open,*** or off, the circuit is broken and does not function. See **Figure 8-8.**

A ***short circuit,*** or "short," is an accidental low-resistance connection that results in excessive current flow. See **Figure 8-9.** If a short to ground exists between the battery and load, ***unlimited current flow*** can melt and burn the wire insulation.

A ***fuse*** protects a circuit against damage caused by a short circuit. The link in the fuse will melt and burn in half to stop excess current and further circuit damage, **Figure 8-10.**

A ***fuse box*** contains fuses, circuit breakers, and flasher units for the various circuits. It is often located under the dashboard.

A ***fusible link,*** or ***fuse link,*** is a small section of wire designed to burn in half when excess current is present in the circuit. It is often used as protection between the battery and main fuse box. If a major wire, like the starting motor wire, is shorted, the fusible link will burn in half to prevent an electrical fire and further damage.

Direct path to ground burns wire
Battery
Short circuit

Figure 8-9. An open circuit has a break in a wire or an electric component. Current stops flowing through the circuit. A short circuit has a wire touching ground. A high amount of current flows through the short.

A ***circuit breaker*** performs the same function as a fuse. It disconnects the power source from the circuit when current becomes too high. See **Figure 8-12.** Normally, a circuit breaker will reset itself when current returns to a normal level.

A ***relay*** is an electrically operated switch. It allows a small dash switch to control another circuit from a distant point. It also allows very small wires to be used behind the dash, while large wires may be needed in the relay-operated circuit. Look at **Figure 8-13.**

Automotive Electronics

Some electrical components, such as relays and circuit breakers, use moving mechanical contacts. These

Current flow

Figure 8-12. A circuit breaker performs the same function as a fuse. High current heats a bimetal strip, causing it to deform and open the contacts. This stops the current flow in the circuit. (Ford)

contact points can wear, burn, or pit. Also, the mechanical parts used in electrical components are relatively slow. In electronic systems, the components are solid state and do *not* have moving parts. Solid state circuits use semiconductors. A ***semiconductor*** is a special substance capable of acting as both a conductor and an insulator. This characteristic enables semiconductor devices to control current without mechanical points. Diodes and transistors are solid state, semiconductor devices.

Diode

A ***diode*** is an "electronic check valve" that allows current to flow in only one direction. See **Figure 8-14.** When a diode is ***forward biased,*** current is entering in correct direction and the diode acts as a conductor. When a diode is ***reverse biased,*** current is trying to enter in the wrong direction and the diode acts as an insulator, stopping current from passing through the circuit.

Transistor

A ***transistor*** performs the same basic function as a mechanical relay. It acts as a remote control switch or current amplifier. However, it is much more efficient than a relay. A transistor can sometimes turn on and off more than 200 times a second. It does this without using moving parts, which can wear and deteriorate. Look at **Figure 8-15.**

Base
Horn switch (closed)
B

Figure 8-15. Basically, relays and transistors perform the same function. They allow a small control current to operate a larger current to a load. A—In a relay system, when the horn button is pressed, a small current enters the relay coil. The coil field attracts the point arm. Then, battery current can reach and operate the horn through the relay. B—In a transistor system, when the horn button is pressed, a small base current enters the transistor. This changes the semiconductor material in the transistor from an insulator to a conductor. Then, current can flow through the transistor and to the horn. (Echlin)

A transistor ***amplifies,*** or increases, a small control or base current. The small base current energizes the semiconductor material, changing it from an insulator to a conductor. This allows the much larger circuit current to pass through the transistor.

Other Electronic Devices

Capacitors are devices used to absorb unwanted electrical pulses, such as voltage fluctuations, in a circuit. They are used in various types of electrical and electronic circuits. A capacitor is often connected to the supply wires going to a car radio. It absorbs any voltage pulses from the alternator or ignition system that would otherwise be heard in the radio speakers as buzzing.

An ***integrated circuit (IC)*** contains microscopic diodes, transistors, resistors, and capacitors in a wafer-like chip. This chip is a small plastic housing with metal terminals. See **Figure 8-16.** Integrated circuits are used in very complex electronic circuits.

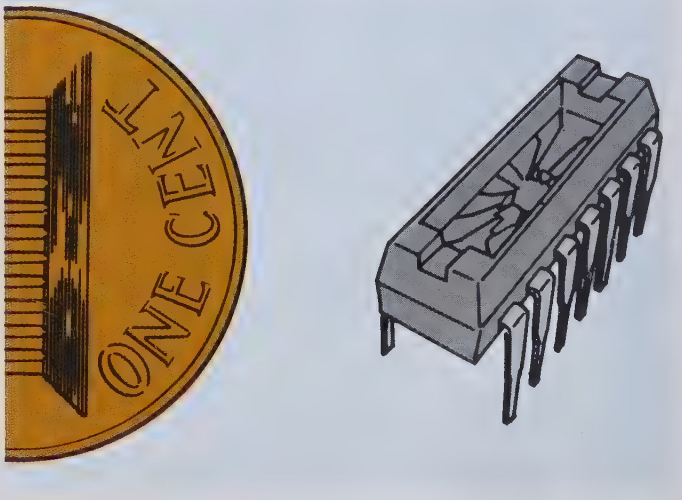

Figure 8-16. An integrated circuit is a tiny chip containing microscopic components such as transistors, diodes, resistors, and conductors. ICs are used in modern electronic circuits.

Printed circuits use flat conductor strips mounted on an insulating board. This is pictured in **Figure 8-17.** Printed circuits are normally used instead of wires on the back of the instrument panel. This eliminates the need for a bundle of wires going to the indicators, gauges, and instrument bulbs.

An ***amplifier*** is an electronic circuit designed to use a very small current to control a very large current. A good example of an amplifier is an ignition control module, which was introduced in Chapter 1. It uses small

electrical pulses from the distributor to produce strong on/off cycles to operate the ignition coil.

Automotive Wiring

An automobile uses various types of wiring in its many electrical systems. It is important that you learn the different types, how they are used, and how to repair them.

Wire size is determined by the diameter of the wire's metal conductor. The wire's conductor diameter is stated in ***gauge size.*** Gauge size is a relative numbering system. The larger the gauge number, the smaller the diameter of wire conductor. When replacing a section of wire, always use wire of equal size. If a smaller wire is used, the circuit may not work due to high resistance. Also, undersize wire may heat up and melt its protective insulation, resulting in an electrical fire.

Lb	Light blue
Lg	Light green
O	Orange
R	Red
W	White
Y	Yellow

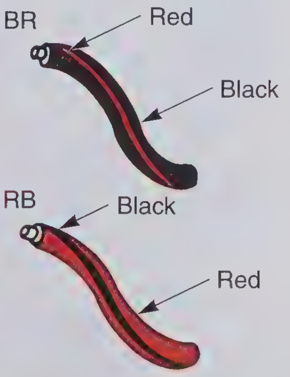

Figure 8-18. Primary wires are color-coded. This lets you trace a wire through the vehicle.

Wire Types

A ***primary wire*** is small and carries battery or alternator voltage. A primary wire normally has plastic insulation to prevent shorting. The insulation is usually color coded for easy troubleshooting, **Figure 8-18.** As shown in **Figure 8-19,** primary wires are often grouped in a wiring harness.

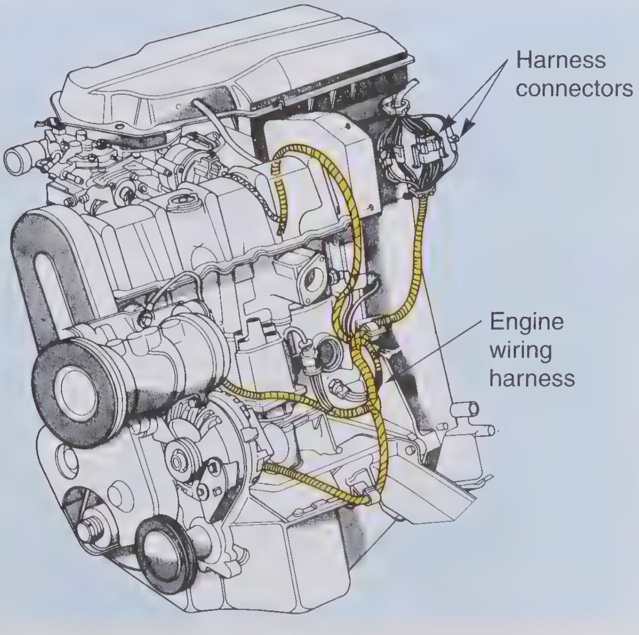

Figure 8-19. A wiring harness usually consists of a plastic covering and a group of primary wires. The covering organizes and protects the wires. Also note the harness connectors. (DaimlerChrysler)

A ***wiring harness*** is a group of wires enclosed in a plastic or tape covering. This covering helps protect and organize the wires.

Secondary wire, also called ***high tension cable,*** is only used in a vehicle's ignition system for spark plug or coil wires. It has extra thick insulation to prevent the high voltage from short circuiting. The conductor is designed for very low current.

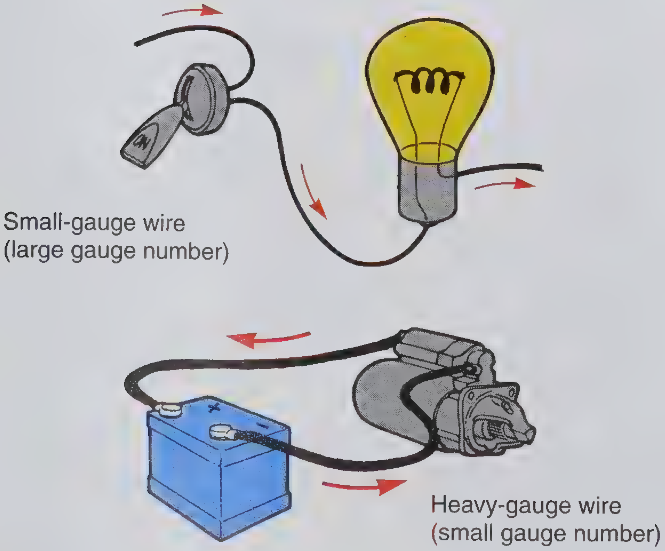
Battery cable is an extremely large-gauge wire capable of carrying high currents from the battery to the starting motor. Look at **Figure 8-20.** Usually, a starting motor draws more current than all of the other electrical components combined, normally over 100 amps. For this reason, a very large conductor is required.

Ground wires or ***ground straps*** connect electrical components to the chassis or ground of the car. Insulation is not used on these wires.

Wiring Repairs

Crimp connectors and ***terminals*** can be used to quickly repair automotive wiring. See **Figure 8-21.** Connectors, or splicers, allow a wire to be connected to another wire. Terminals allow a wire to be connected to an electrical component.

Harness connectors are multi-wire terminals that connect several wires together. They usually have a two-part plastic housing that snaps together. To free, or disconnect, a harness connector, you must usually disengage a tab or plastic clip that secures the two halves. Designs vary, so look at the connector carefully before attempting to disengage it to prevent damage.



Small-gauge wire
(large gauge number)
Heavy-gauge wire
(small gauge number)

Figure 8-20. Wire gauge size is matched to current draw. Small gauge will only handle small current. Larger gauge is needed for high current draws, such as for a starting motor.

Figure 8-21. Various types of wire terminals and connectors. (Belden, General Motors, Honda)

Crimping pliers are used to deform the connector or terminal around the wire. **Figure 8-22** shows a technician installing a crimp terminal.

A soldering gun or iron can also be used to permanently fasten wires to terminals or to other wires, **Figure 8-23.** The ***soldering gun*** produces enough heat to melt solder. The soldering gun is first touched to the wire and other component to preheat them. Then, the solder is touched to the joint and melts. When cooled, the solder makes a solid connection between the electrical components.

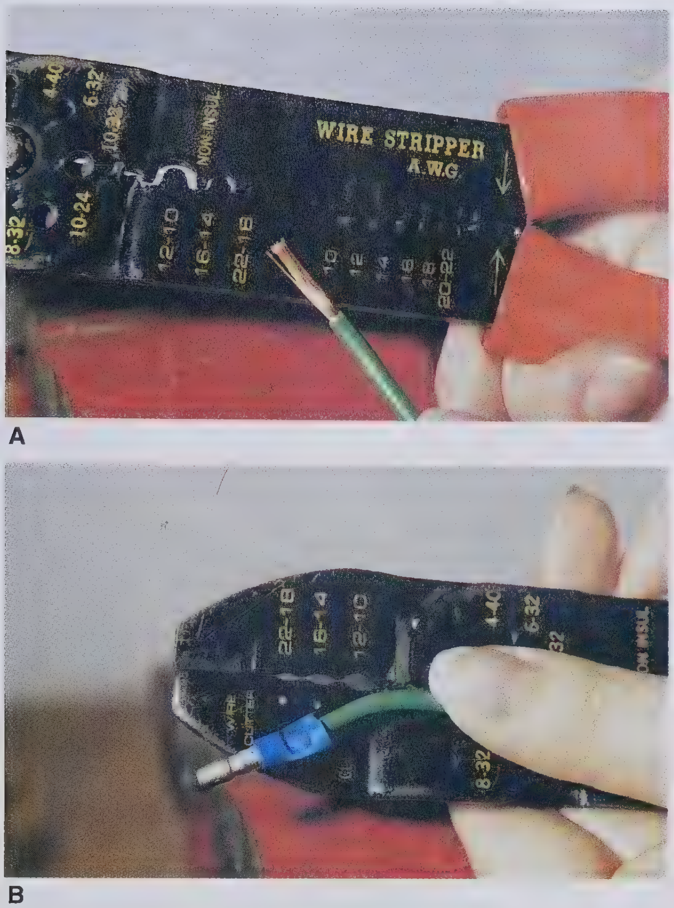

Figure 8-22. Installing crimp-type connectors and terminals. A—Strip off a short section of insulation. B—Use the correct-size crimping jaw to form the terminal or connector around the wire. Tug on the wire lightly to check the connection. (Vaco Tool)

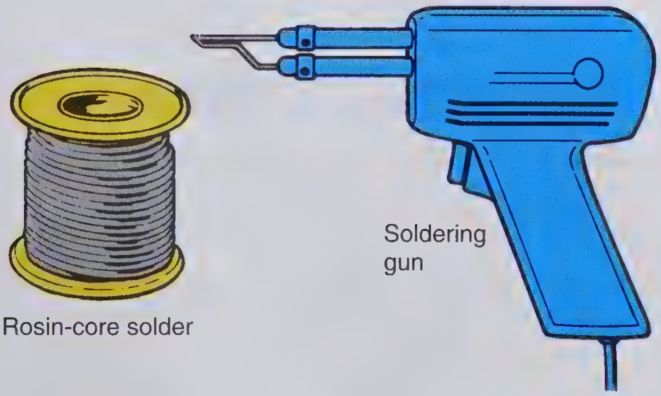

Figure 8-23. Rosin-core solder and a soldering gun make permanent connections between wires and components.

Rosin-core solder should be used on all electrical repairs. It is usually purchased in a roll for easy use and handling. ***Acid-core solder*** can cause corrosion of electrical components. It is recommended for nonelectrical repairs, such as radiator and heater core repairs.

Caution!
Most late-model electrical connectors require special methods or a special tool during disconnection. If you simply force the connector apart, it can break. This will create a new problem—a poor electrical connection. There are many connector designs and special tools available. Always use the right tool and methods when disconnecting wiring harnesses.

Basic Electrical Tests

Various electrical tests and testing devices are used by an auto technician. To be prepared for later chapters, you should have a general understanding of these tools and how to use them.

Jumper Wires and Test Lights

A ***jumper wire,*** or jumper, is handy for testing switches, relays, solenoids, wires, and other components. The jumper can be substituted for the component, as shown in **Figure 8-24.** If the circuit begins to function with the jumper in place, then the component being bypassed is defective.

A ***test light*** is used to quickly check a circuit for power, or voltage. It has an alligator clip that connects to ground. Then, the pointed tip can be touched to the circuit to check for voltage. If there is voltage, the light will glow. If it does not glow, there is an open or break between the power source and the test point. See **Figure 8-25.**

A ***self-powered test light*** contains a battery and is used to check for continuity, or a complete electrical path, between two test points. To use a self-powered test light, disconnect the normal source of power from the circuit or component in question. Then connect the test light across the circuit or component. If the light glows, the

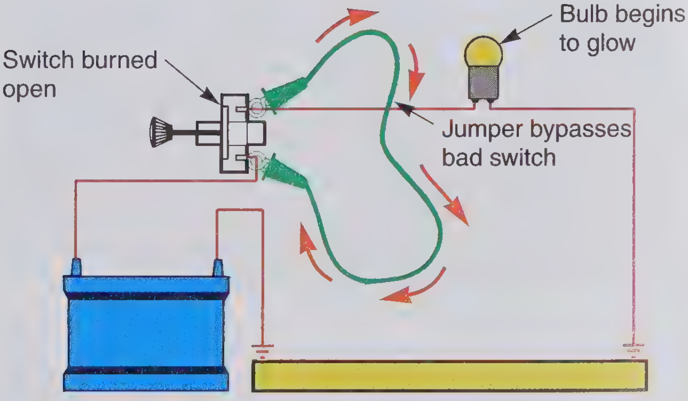

Figure 8-24. A jumper wire is handy for bypassing electrical components. It can also be used to supply power to a section of a circuit. (Ford)

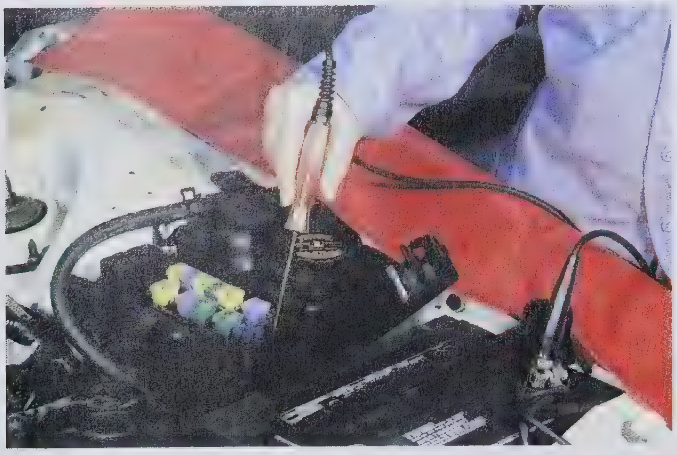

Figure 8-25. A test light will quickly check for power in a circuit. Connect the alligator clip to ground and touch the tip to the circuit. The light will glow if there is power in the circuit.

circuit or part has continuity. If the light does *not* glow, there is an open, or break, between the test points in the circuit.

Tech Tip!

Some test lights have a built-in flashlight. This is handy when probing circuits and wires in poorly lit areas, like under the dash. They will save time and pay for themselves in a short period.

Voltmeter, Ammeter, Ohmmeter

A ***voltmeter*** is used to measure the amount of voltage, or electrical pressure, in a circuit, **Figure 8-26A.** It is normally connected across, or in parallel with, the circuit. The voltmeter reading can be compared to specifications to determine whether an electrical problem exists.

An ***ammeter*** measures the amount of current, or electron flow, in a circuit, **Figure 8-26B.** Conventional types must be connected in *series* with the circuit. All the current in the circuit must pass through the ammeter.

A modern ***inductive,*** or ***clip-on, ammeter*** is simply slipped over the outside of the wire insulation. It uses the magnetic field around the outside of the wire to determine the amount of current in the wire. An inductive ammeter is very fast and easy to use.

An ***ohmmeter*** will measure the amount of electrical resistance in ohms in a circuit or component. To prevent damage, an ohmmeter must *never* be connected to a source of voltage. The wire or part being tested must be disconnected from the vehicle's battery.

As shown in **Figure 8-26C,** the ohmmeter is connected across the wire or component being tested. Then, the ohmmeter reading can be compared to specifications. If the resistance is too high or too low, the part is defective.

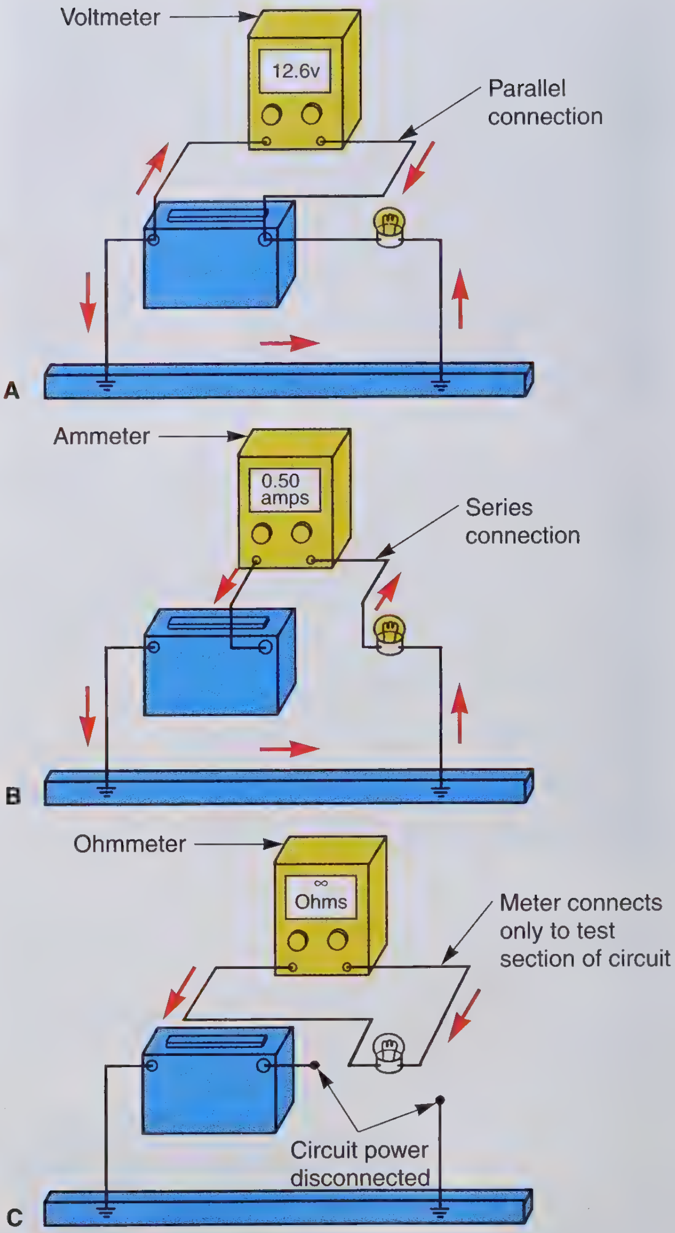

Figure 8-26. Three basic meter connections. A—A voltmeter connects in parallel. It measures the amount of electrical pressure, or potential, in a circuit. B—An ammeter connects in series with the circuit. Current flows through the meter and circuit. C—An ohmmeter is connected to the circuit with the power disconnected. Voltage can damage some ohmmeters.

A ***multimeter,*** also called a ***VOM,*** is an ohmmeter, ammeter, and voltmeter combined in one case. As pictured in **Figure 8-27,** a function knob can be turned to select the type measurement to be made, such as volts, amps, or ohms. The multimeter's test lead connections to the circuit will depend on whether you are using it as a voltmeter, an ammeter, or an ohmmeter. Hookups will be the same as those described for the individual meters.

B—This is a digital-analog meter face. The number display gives a digital readout. The bar across the bottom is an analog readout for interpreting fluctuating values.

Caution!
Only use a high-resistance test light or meter when probing today's vehicle circuits. If you use an older low-resistance, high-current-draw test light or meter, you can damage delicate electronic components.

Wiring Diagrams

A ***wiring diagram*** shows how electrical components are connected by wires. It serves as an "electrical map" to help the technician with difficult electrical repairs. Look at **Figure 8-28.**

Wiring diagrams use ***symbols*** to represent the electrical components in a circuit. The lines on the diagram represent the wires. In this way, each wire can be traced to see how it connects to each component.

Oscilloscope

An ***oscilloscope,*** or ***scope,*** is an electronic measuring instrument. It obtains the same type of information as a voltmeter. However, a scope displays voltage readings as a ***trace,*** or line, on a display screen. This allows a scope to show voltage variations very accurately as a ***waveform.***

Voltage is shown as an up or down movement of the trace. Time is shown horizontally. A scope is usually built as part of an engine analyzer that can do other functions besides voltage measurement. See **Figure 8-29.**

Figure 8-29. An oscilloscope is a graphic voltmeter. It displays voltage and time as a line on the display screen. It is needed when analyzing rapidly changing voltage values, such as ignition or computer system voltages. This is a dual trace scope that is showing two square waves simultaneously. (Snap-On Tools)

A ***dual-trace scope*** can read and show two separate waveforms or traces. This is handy if you need to compare the timing or amplitude of two voltage levels simultaneously when doing advanced troubleshooting.

Scan Tools

A ***scan tool*** is a diagnostic tool that helps find and diagnose vehicle problems, **Figure 8-30.** It is an electronic unit that plugs into the vehicle's diagnostic connector, **Figure 8-31.** It can then communicate with the vehicle's control module to tell you which part might be at fault. For more information on scan tools, scopes, and other advanced electronic tools, refer to the index. Many other sections of this book discuss their use in more detail.

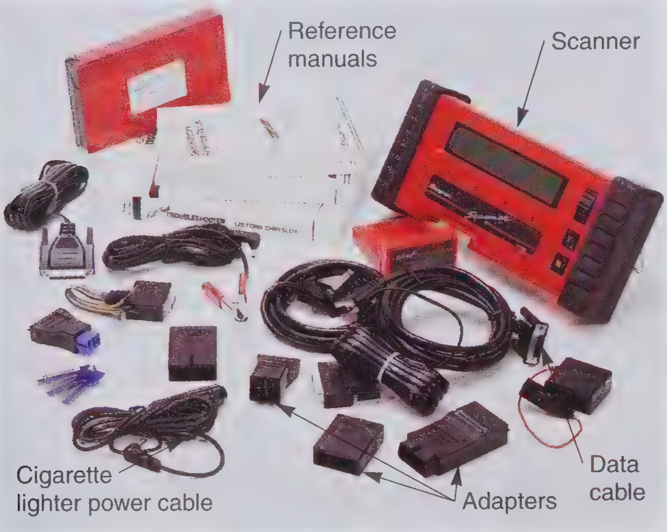

Figure 8-30. A scan tool is used to help find computer system troubles. It exchanges data with the vehicle computer and tells which part of the computer circuit might be at fault. (Snap-On Tools)

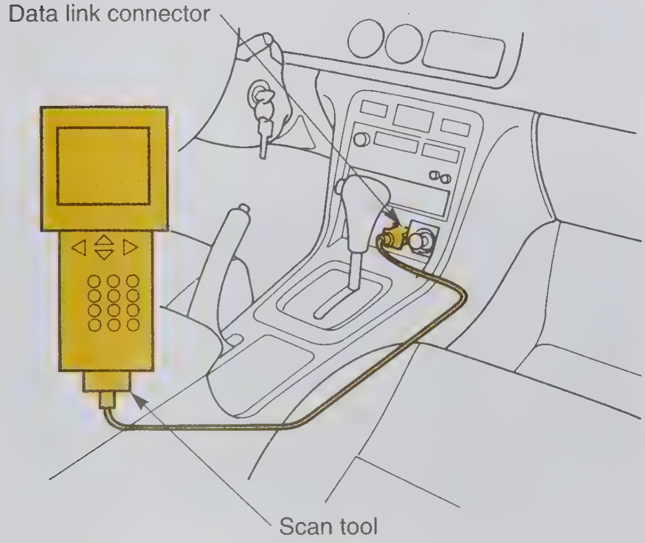

Figure 8-31. A scan tool plugs into the vehicle's data link connector, or diagnostic connector. Then, the scan tool can give instructions on testing the computer system for faults. Most scan tools convert trouble code numbers into a brief description of what might be wrong with the computer system. (Honda)

Note!
The principles of electronics are explained in numerous other chapters. The chapters on starting systems, charging systems, fuel systems, and computer systems all cover this topic. Refer to the index as needed for added information.

Customer Relations

Always "go the extra mile" to improve customer satisfaction. For example, you might want to place faulty parts in a plastic bag to show your customer. This will help demonstrate the shop's integrity and show the customer that you want them to understand your repair work.

Summary

- Almost every system in a vehicle uses some type of electric or electronic component.
- An atom consists of small particles called protons, neutrons, and electrons.
- Negatively charged electrons circle around neutrons and protons.
- Current (abbreviated I) is the *flow* of electrons through a conductor.
- Voltage (abbreviated V or E) is the force that causes electron flow.
- Resistance (abbreviated R) is the *opposition* to current flow.
- Ohm's law is a simple formula for calculating volts, amps, or ohms when two of the three values are given.
- If a wire passes through a magnetic field, an electric current is generated in the wire.
- When a switch is closed, a circuit is complete. When the switch is open, a circuit is broken and does not function.
- A fuse protects a circuit against damage caused by a short circuit.
- A relay is an electrically operated switch.

- A semiconductor is made of a special substance capable of acting as both a conductor and an insulator.
- A diode is an "electronic check valve" that only allows current to flow in one direction.
- A transistor performs the same basic function as a relay. It acts as a remote control switch or current amplifier.
- A condenser or capacitor is a device used to absorb unwanted electrical pulses in a circuit.
- An integrated circuit (IC) is a wafer-like chip that contains microscopic diodes, transistors, resistors, and capacitors.
- A jumper wire is handy for testing switches, relays, solenoids, wires, and other components.
- A multimeter, also called a VOM, is an ohmmeter, ammeter, and voltmeter combined in one case.
- A wiring diagram shows how electrical components are connected by wires.

Review Questions—Chapter 8

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What is electricity?
2. Explain the difference between a conductor and an insulator.
3. Which of the following is *not* part of a simple circuit?
   (A) Wheatstone bridge.
   (B) Load.
   (C) Power source.
   (D) Conductors.
4. List and explain the three basic elements of electricity.
5. A(n) _____ circuit has more than one load connected in a single electrical path.
6. A(n) _____ circuit has more than one electrical path or leg.
7. What is a one-wire circuit?
8. Using Ohm's law, find the resistance in a circuit with 12 volts and 3 amps.
9. Define the term "short circuit."
10. Explain the functions of fuses and circuit breakers.
11. A(n) _____ is an electrical, not electronic, device that allows a small current to control a larger current.
12. Explain the difference between an electric component and an electronic component.
13. Which of the following is not an electronic component?
    (A) Diode.
    (B) Transistor.
    (C) Circuit breaker.
    (D) Integrated circuit.
14. A(n) _____ is an electronic circuit that uses a very small current to control a very large current.
15. A(n) _____ wire is used to carry battery voltage and has plastic insulation.
16. Why are wires color coded?
17. Which of the following should *not* be used for electrical repairs?
    (A) Acid-core solder.
    (B) Rosin-core solder.
    (C) Crimp connectors.
    (D) Soldering gun.
18. Explain the use of a test light, voltmeter, ohmmeter, ammeter, and wiring diagrams.

19. Which of the following devices is used to absorb unwanted voltage fluctuations in a circuit?
    - (A) Diode.
    - (B) Capacitor.
    - (C) Transistor.
    - (D) Multimeter.
20. While repairing a section of wire, Technician A believes the segment of replacement wire should be larger than the old wire for smoother flow. Technician B believes the section of new wire should be smaller for improved performance. Who is right?
    - (A) A only.
    - (B) B only.
    - (C) Both A and B.
    - (D) Neither A nor B.

ASE-Type Questions

1. Technician A says that all things are made of atoms. Technician B says that only some atoms allow current flow. Who is correct?
    - *(A) A only.*
    - *(B) B only.*
    - *(C) Both A and B.*
    - *(D) Neither A nor B.*
2. The movement of electrons from atom to atom is called:
    - *(A) induction.*
    - *(B) electricity.*
    - *(C) atomic flow.*
    - *(D) conductivity.*
3. Each of these is an insulator *except:*
    - *(A) metal.*
    - *(B) plastic.*
    - *(C) rubber.*
    - *(D) ceramics.*
4. The three basic elements of electricity are:
    - *(A) watts, volts, and ohms.*
    - *(B) current, voltage, and resistance.*
    - *(C) Both A and B.*
    - *(D) Neither A nor B.*
5. The electron theory of flow states that current flows from:
    - *(A) electrons to volts.*
    - *(B) atoms to a current.*
    - *(C) positive to negative.*
    - *(D) negative to positive.*
6. Which of the following is abbreviated by an I?
    - *(A) Current.*
    - *(B) Voltage.*
    - *(C) Resistance.*
    - *(D) None of the above.*
7. Technician A says a simple circuit has only one path for current. Technician B says a series circuit has more than one path for current. Who is right?
    - *(A) A only.*
    - *(B) B only.*
    - *(C) Both A and B.*
    - *(D) Neither A nor B.*
8. Which type of circuit uses a vehicle body as a return wire to the power source?
    - *(A) Series.*
    - *(B) Parallel.*
    - *(C) One-wire.*
    - *(D) Series-parallel.*
9. Which of the following is *not* a correct example of Ohm's law?
    - (A) $E = I \times R$.
    - (B) $R = I \times E$.
    - (C) $R = E \div I$.
    - (D) $I = E \div R$.
10. Which of the following is an electronic check valve that will only allow current to flow in one direction?
    - *(A) Diode.*
    - *(B) Relay.*
    - *(C) Transistor.*
    - *(D) Condenser.*

Activities—Chapter 8

1. Using sketches and principles you have learned about basic electricity, prepare a presentation showing how electricity can be created through magnetism.
2. Demonstrate the use of a continuity tester and explain what it tells you about a circuit.
3. Using the pie chart in **Figure 8-6,** solve the following problem: If a circuit with 12 volts has a current of 2 amperes, what is the resistance? Explain how you got the answer.

9

Fasteners, Gaskets, Seals, and Sealants

After studying this chapter, you will be able to:

- Identify commonly used automotive fasteners.
- Select and use fasteners properly.
- Remove, select, and install gaskets, seals, and sealants correctly.
- Summarize safety rules relating to fasteners, gaskets, seals, and sealants.
- Correctly answer ASE certification test questions that require a knowledge of fasteners, gaskets, seals, and sealants.

Many different fasteners, gaskets, seals, and sealants are used by the automotive technician. It is almost impossible to connect any two parts of a vehicle without them. The information presented in this chapter is important and will prepare you for many repair operations and other text chapters.

Fasteners

Fasteners are devices that hold the parts of a car together. Thousands of fasteners are used in vehicles. **Figure 9-1** shows some of the most common types.

Bolts and Nuts

A ***bolt*** is a metal rod with external threads on one end and a head on the other. When a high-quality bolt is threaded into a part other than a nut, it can also be called a ***cap screw.*** A ***nut*** has internal threads and usually a

six-sided outer shape. When a nut is screwed onto a bolt, a powerful clamping force is produced, **Figure 9-2.**

In automotive technology, bolts and nuts are named after the parts they hold. For instance, the bolts holding the cylinder head on the block are called cylinder head bolts. The bolts on an engine connecting rod are called connecting rod bolts.

Bolt and Nut Terminology

Bolts and nuts come in various sizes, grades (strengths), and thread types. It is important to be familiar with these differences. The most important bolt dimensions are:

- ***Bolt size***—the measurement of the outside diameter of the bolt threads. See **Figure 9-3.**
- ***Bolt head size***—the distance across the flats or outer sides of the bolt head. It is the same as the wrench size.
- ***Bolt length***—measured from the bottom of the bolt head to the threaded end of the bolt.
- ***Thread pitch***—the same as thread coarseness. With U.S. conventional system fasteners, thread pitch is the number of threads per inch. With metric fasteners, it is the distance between each thread in millimeters. Refer again to **Figure 9-3.**

Thread Types

There are three basic types of threads used on fasteners:

- *Coarse threads* (UNC-Unified National Coarse).
- *Fine threads* (UNF-Unified National Fine).
- *Metric threads* (SI).

G
-9.8
F
F — Property class (bolt strength)
G — Head size (millimeters)
H — Thread pitch (thread with crest to crest/mm)
I — Nominal diameter (bolt size in millimeters)
J — Length (millimeters)

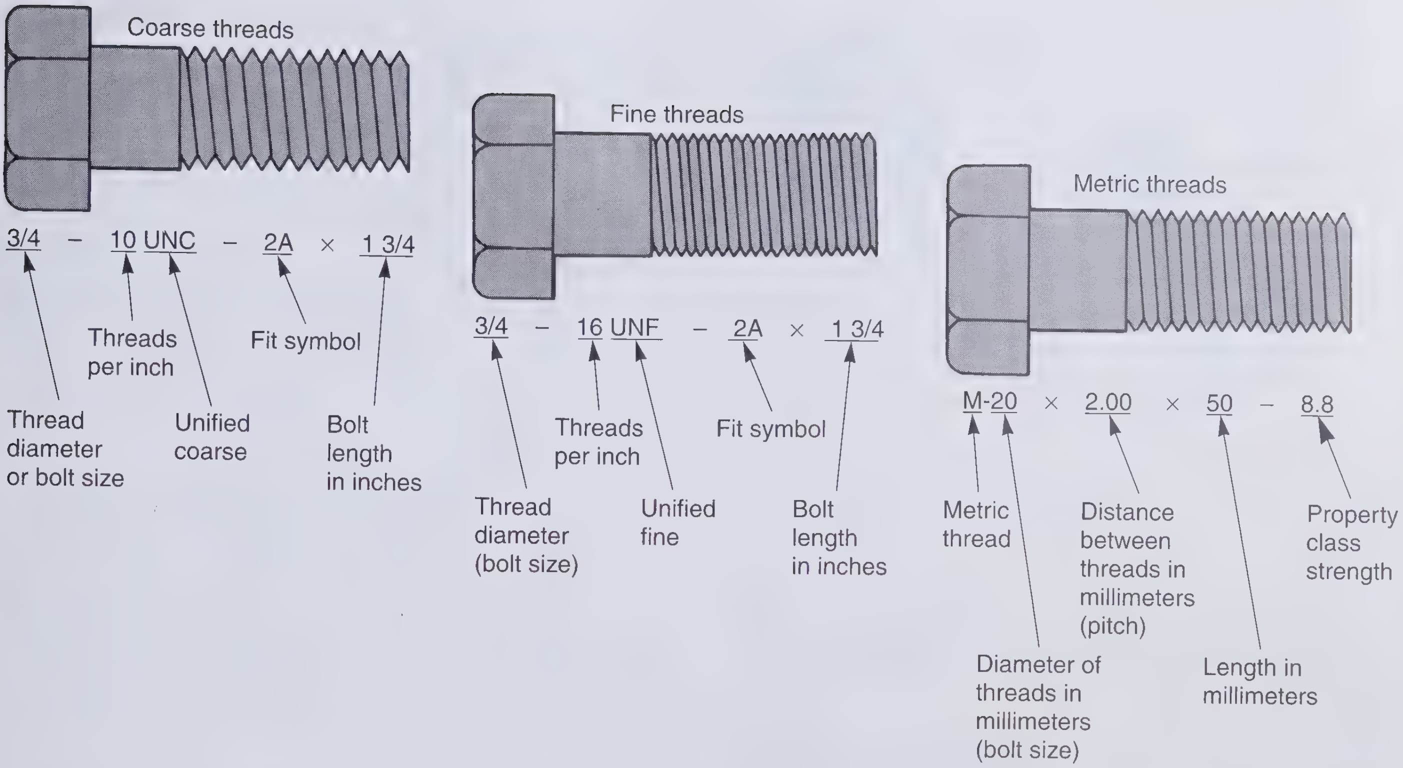
Figure 9-3. The naming systems for both customary and metric bolts. (Ford)

Never interchange thread types or thread damage will result. As shown in **Figure 9-4,** metric threads *look* like customary threads. If a metric bolt is forced into a hole with fine threads, either the bolt or part threads will be ruined.

Bolts and nuts also come in right- and left-hand threads. With ***right-hand threads,*** the fastener must be turned clockwise to tighten. This is the most common style of thread. With ***left-hand threads,*** turn the fastener in a counterclockwise direction to tighten. Left-hand threads are not very common. The letter L may be stamped on fasteners with left-hand threads.

Bolt Grade

Tensile strength, or ***grade,*** refers to the amount of pull a fastener can withstand before breaking. Bolts are made of different metals, some stronger than others. Tensile strengths can vary. ***Bolt head markings,*** also called ***grade markings,*** specify the tensile strength of the bolt. U.S. customary bolts are marked with lines or slash marks. The more lines, the stronger the bolt. A metric bolt is marked with a numbering system. The larger the number, the stronger the bolt. Look back at **Figure 9-3.**



Coarse threads
3/4 – 10 UNC – 2A × 1 3/4
Threads per inch
Fit symbol
Thread diameter or bolt size
Unified coarse
Bolt length in inches
Fine threads
3/4 – 16 UNF – 2A × 1 3/4

Metric thread
Distance between threads in millimeters (pitch)
Property class strength
Diameter of threads in millimeters (bolt size)
Length in millimeters

Figure 9-4. The bolt designation number gives information about the bolt. This number is commonly used when purchasing new bolts.

Warning!
Never replace a high-grade bolt with a lower grade bolt. The weaker bolt could easily snap, possibly causing part failure and a dangerous situation.

Bolt Description

A ***bolt description*** is a series of numbers and letters that describe the bolt, as shown in **Figure 9-4.** When purchasing new bolts, the bolt description information is needed.

Nut Types

Many types of nuts are used in a vehicle. The most common ones are pictured in **Figure 9-5.** Study their names closely. A slotted nut, or castle nut, uses a safety device called a ***cotter pin.*** The cotter pin fits through a hole in the bolt or part. This keeps the nut from turning and possibly coming off. Look at **Figure 9-6.**

Washers

Washers are used under bolt heads and nuts. The two basic types are flat washers and lock washers. Look at

Nut
Castle nut
Bolt

Figure 9-6. A cotter pin slides through a castle nut and a hole in the bolt. This makes sure the nut cannot turn and come off. (Deere & Co.)

Figure 9-7. A ***flat washer*** increases the clamping surface under the fastener. It prevents the bolt or nut from digging into the part.

A ***lock washer*** prevents the bolt or nut from becoming loose under stress and vibration. ***Lock tabs,*** or ***lock plates,*** perform the functions of both flat washers and lock washers. They increase clamping surface area and secure the fastener.

Machine Screws

Machine screws are similar to bolts, but they normally have screw-type heads. They are threaded along their full length and are relatively small. Refer back to **Figure 9-1**. Machine screws are used to secure parts when clamping loads are light. They come in various head shapes.

Sheet Metal Screws

Sheet metal screws, or ***tapping screws,*** are commonly used on plastic and sheet metal parts, such as body trim, dashboard panels, and grills. Several are shown in **Figure 9-8.** Sheet metal screws have tapering threads that are very widely spaced. They come in a wide range of head configurations and sizes.

Figure 9-7. Basic washer types. A—Plain flat washer. B—Split lock washer. C—Toothed lock washer. D—Lock plate.

Nonthreaded Fasteners

Numerous types of ***nonthreaded fasteners,*** such as snap rings, clips, and adhesives, are used in the assembly of a vehicle. It is essential to learn the most common types.

Snap Rings

A ***snap ring*** fits into a groove in a part and commonly holds shafts, bearings, gears, pins, and other components in place. **Figure 9-9** shows several types of snap rings. ***Snap ring pliers*** are needed to remove and install snap rings. As pictured in **Figure 9-9,** these pliers have special jaws that fit and grasp the snap ring.

External snap ring
Internal snap ring

Figure 9-9. Different snap ring types. External snap rings fit into a groove on a shaft. Internal snap rings fit into a groove inside a hole.

Warning!
Wear eye protection when working with a snap ring. When flexed, the ring can shoot into your face with considerable force.

Keys and Set Screws

A metal ***key*** fits into a ***keyseat,*** or slot, cut into a shaft and a ***keyway*** cut into the mating part, such as a gear, pulley, or collar. The key prevents the part from turning on its shaft. Refer to **Figure 9-10A.** ***Set screws*** are normally used to lock a part onto a shaft. See **Figure 9-10B.** They can be used with or without a key and keyway. A set screw is a headless fastener normally designed to accept a hex (Allen) wrench or screwdriver.

Splines

Splines are a series of slots cut into a shaft and a mating part. See **Figure 9-11.** Splines have an advantage over keys in that they allow the gear or collar to slide on the shaft but still *not* rotate. This sliding locking action is commonly used in manual transmissions, clutches, and drive shaft yokes.

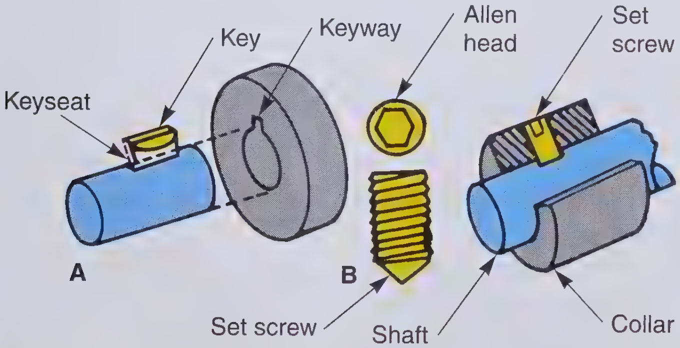

Figure 9-10. A—A key fits into the keyseat, or slot, in a shaft and keyway in the mating part. This keeps the part from turning on the shaft. B—A set screw also locks a part to a shaft, but with less strength. (Florida Dept. of Voc. Ed.)

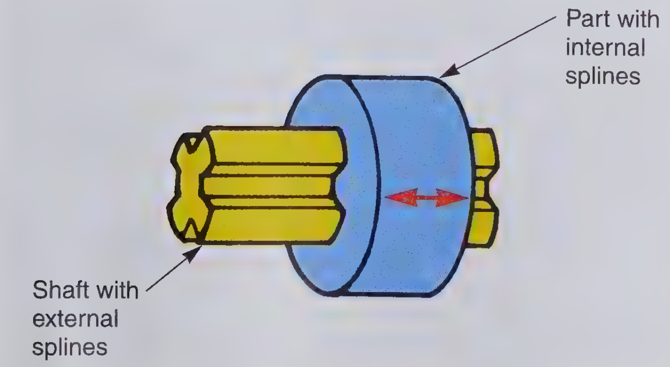

Figure 9-11. Splines allow a part to slide on a shaft, but not turn on the shaft.

Adhesives

Adhesives are special glues widely used in vehicles. They hold body moldings, rubber weather stripping, and body emblems. Some adhesives are designed to stay soft and pliable; others dry hard. Some take hours to dry, while others dry in seconds. Observe all directions and safety precautions when using adhesives.

Torquing Bolts and Nuts

It is very important that bolts and nuts be tightened properly. This is called ***torquing.*** If overtightened, a bolt will stretch and possibly break. The threads could also fail. If undertightened, a bolt may loosen and fall out. Part movement could also shear the fastener or break a gasket, causing leakage.

Torque specifications are tightening values given by the auto manufacturer. Torque specifications are normally given for all precision assemblies, such as engines, transmission, and differentials. **Figure 9-12** shows a general torque specification chart that gives average bolt tightening values. It can be used when factory specifications are not available. Notice how bolt torque increases with bolt size and grade.

Service manuals sometimes recommend *new* bolts because of a torque-to-yield process. Discard the old bolts in such cases. ***Torque-to-yield*** is a bolt tightening method that requires the bolt to be tightened to a specific torque and *then* turned an additional number of degrees. After the fastener is torqued to specification, a degree wheel adapter is placed between the torque wrench and socket. The fastener is then turned until the degree wheel reads as specified by the manufacturer. This stretches the bolt to its correct yield point and preloads the fastener for better clamping under varying conditions.

Torque stretch is determined by measuring bolt length change while torquing the bolt. For example, when building a racing engine, you can "mike" connecting rod bolts to measure the length before and after tightening. Too much stretch indicates bolt weakness. Not enough stretch may indicate thread problems affecting torque.

Bolt Tightening Sequence

A ***bolt tightening sequence,*** or pattern, is used to make sure that parts are fastened evenly. An incorrect sequence or uneven tightening can cause breaks,

Caution

The torque specifications listed below are approximate guidelines only and may vary depending on conditions when used such as amount and type of lubricant, type of plating on bolt, etc.

Figure 9-12. A general bolt torque chart. Note how torque values increase as the bolt size and grade increase.

warping, gasket leaks, and other problems. Generally, a group of fasteners on a part are tightened in a ***crisscross pattern.*** This creates an even, gradual clamping force along the entire mating surface of the parts. A service manual will illustrate the proper sequence when a torque pattern is critical. Refer to **Figure 9-13.**

Tech Tip!

When tightening engine covers and covers on other large assemblies, remember that "less is usually better." The most common mistake is to overtighten covers and damage or split the gasket or seal. It usually takes much less torque than you may think to make a new gasket seal properly.

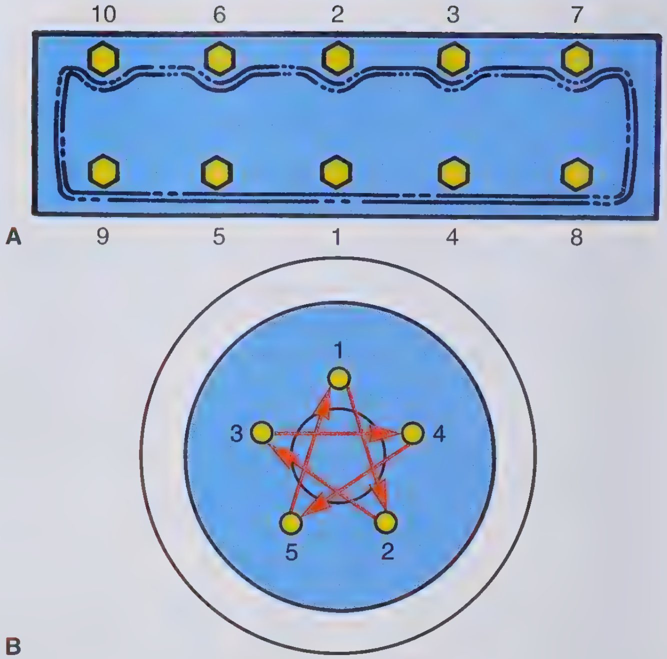

Figure 9-13 A crisscross pattern is recommended when multiple fasteners hold a part. A—A service manual pattern for engine cylinder head. B—A service manual pattern for wheel lug nuts.

Using a Torque Wrench

A ***torque wrench*** is used to apply the proper amount of torque when tightening a threaded fastener. Use the following basic rules.

- Keep a steady pull on the wrench. Do *not* use short, jerky motions.
- Clean fastener threads.
- When possible, avoid using swivel joints. They can affect torque wrench accuracy.
- When reading a torque wrench, look straight down at the scale. Viewing the scale from an angle can give a false reading.
- A general torque value chart should only be used when the manufacturer's specifications are *not* available.
- When the manufacturer's torque patterns are not available, use a general crisscross pattern for tightening fasteners.
- Pull only on the handle of the torque wrench. *Do not* allow beam of a beam-type torque wrench to touch anything.
- Tighten bolts and nuts in four steps: one-half recommended torque, three-fourths torque, full torque, and full torque a second time.

- Retorque when required. On some assemblies, such as cylinder heads, intake manifolds, and exhaust manifolds, bolts may have to be retightened after operation and heating. This is because expansion and contraction due to temperature changes can cause the fasteners to loosen.

Caution!
Many late-model parts are made of plastic or composite materials. These parts are more delicate than metal parts and are easily damaged from overtorquing.

Thread Repairs

Threaded holes in parts can become damaged, requiring repairs. A technician must be capable of repairing damaged threads quickly and properly.

Minor Thread Repairs

Minor thread damage includes nicks, partial flattening, and other less serious problems with the fastener or part. Minor thread damage can usually be repaired with a thread chaser, **Figure 9-14.** A ***thread chaser*** "cleans up" slightly damaged internal and external threads. The chaser is run through or over the threads to restore them.

Major Thread Repairs

Major thread damage generally includes badly smashed or stripped threads. Sometimes, major thread damage is repaired with either a tap or die, **Figure 9-15.** A ***tap*** is a threaded tool for cutting internal threads in holes. Various tap shapes are available. Some are for starting the threads. Others are for cutting the threads all the way to the bottom of a hole. A ***die*** cuts external threads. It can be used to cut threads on metal rods, bolts, shafts, and pins.

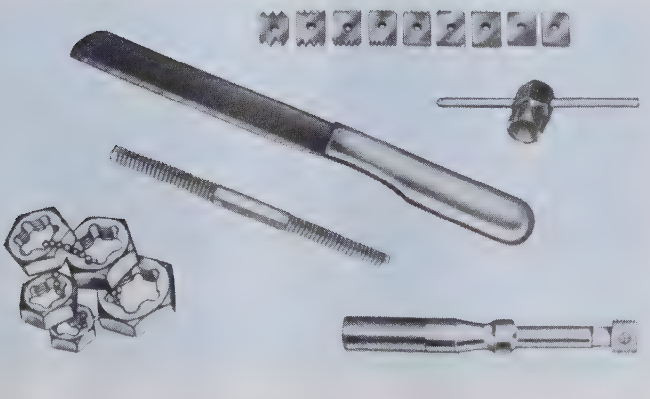

Figure 9-14. Thread chasers or files are used to repair threads. (Snap-On Tools)

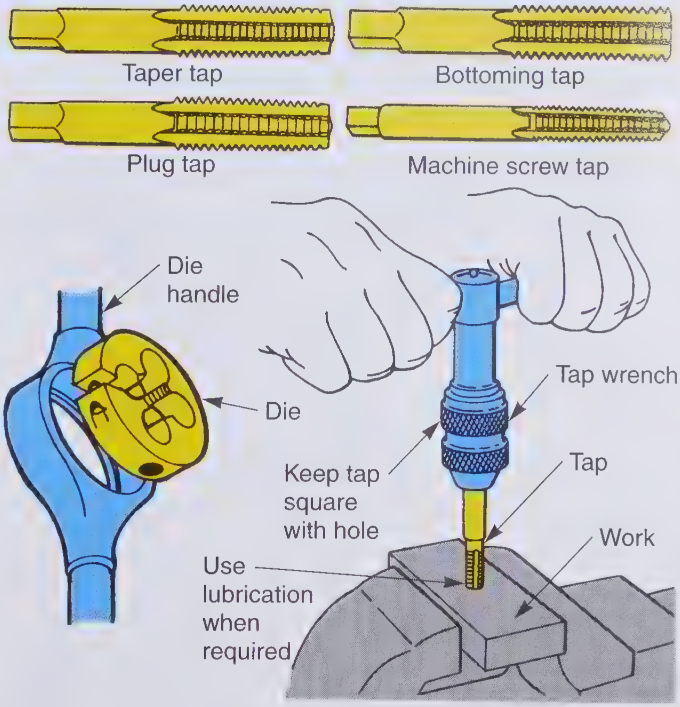

Figure 9-15. A tap or die fits into a special handle. The handle is held square as the bit is turned into the work. Back the handle off to clean metal out of the threads. A taper tap is used to start threads in a hole. Then, a plug tap and a bottoming tap are used to cut the threads to the bottom of the hole.

Taps and dies are mounted in special handles called ***tap handles*** or ***die handles***. See **Figure 9-15.** The tool must be held squarely while being rotated into the work. As soon as the tap or die begins to bind, back the tool off about a quarter turn. This clears away the metal cuttings. Then, the cut can be made another half turn deeper. Keep rotating a half turn in and a quarter turn out until the cut is complete.

Tap and Die Rules

- Never force a tap handle or the tool may break. Back off the handle to clean out metal shavings.
- Keep the tap and die well oiled to ease cutting.
- Always use the right size tap in the correct size hole.
- Use coarse threads when threading or tapping into soft metal, like aluminum. Coarse threads hold better than fine threads.

Tapping Oversize

When a thread chaser or tap cannot be used to clean up damaged threads, the hole can be drilled and tapped

Figure 9-16. A tap drill chart tells you what size hole should be drilled for different taps. The drill bit size is in two right columns. The tap or bolt size is in left column.

oversize. A ***drill and tap size chart*** is used to determine right size drill bit and tap, **Figure 9-16.** For example, a 27/64″ drilled hole should have a 1/2″ coarse tap used in it. First, drill the hole one diameter or size larger than the original hole. Then, cut new threads in the drilled hole with the correct size tap. A larger bolt can then be installed in the threaded hole.

Thread Repair Insert

A ***thread repair insert*** should be used when the use of an oversize hole and fastener is not acceptable. An insert takes the place of damaged internal threads and allows the use of the original-size bolt.

To use a thread repair insert, drill the hole oversize as described in the insert manufacturer's instructions. Then, tap the hole. Finally, screw the insert into the threaded hole. The inside of the insert contains threads that are the same size as those in the original hole. See **Figure 9-17.**

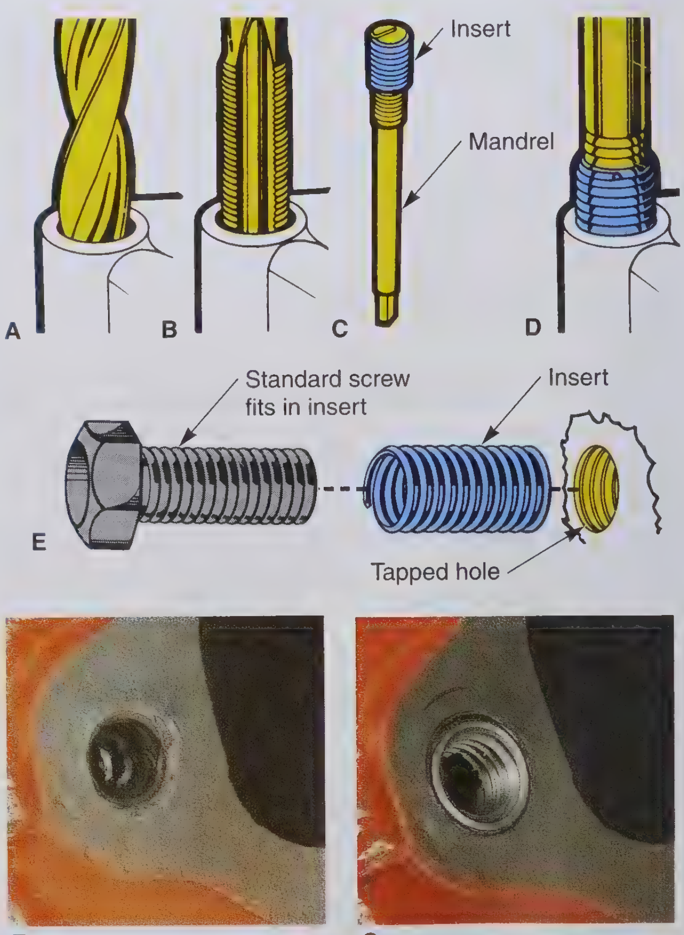

Figure 9-17. Using an insert to repair stripped threads. A—First, drill the hole oversize. B—Next, tap the hole oversize. C—Mount the insert on a mandrel. D—Thread the insert into the hole. E—The insert allows the use of the original-size bolt. F—Damaged threads before a repair. G—An installed insert. (Buick, Chrysler, and The Eastwood Company)

Removing Damaged Fasteners

An automotive technician must be able to remove broken bolts, screws, and studs, as well as fasteners with rusted or rounded-off heads. Certain tools and methods are needed for removing problem fasteners. Refer to **Figure 9-18.**

- ***Locking pliers*** can sometimes be used to remove fasteners with heads that are badly rusted and rounded off. Lock the pliers tightly on the bolt or nut for removal.
- A ***stud puller,*** or ***stud wrench,*** can remove studs and bolts broken off above the surface of the part. This tool is also used to install studs. Position the stud puller so that it will not clamp onto and damage the threads.
- In some cases, broken fasteners are too short to grasp with any tool. Either cut a slot in the fastener with a hacksaw or weld on another bolt head. Then use a screwdriver or wrench to unscrew the broken bolt.
- When the fastener is broken *flush* with the part surface, a ***hammer*** and ***punch*** can sometimes be used to remove it. Angle the punch so that blows from the hammer can drive out the broken fastener.
- A ***screw extractor,*** or "easy-out," can also be used to remove bolts that are broken flush or below the part surface. See **Figure 9-19.** To use a screw extractor, drill a hole in the center of the broken fastener. Then, lightly tap the extractor into the hole using a hammer. Finally, unscrew the broken bolt by turning the extractor with a wrench.
- On some broken bolts, you may have to drill a hole almost as large as the inside diameter of the threads. Then, use a tap or punch to remove the thread shell. The thread shell is the thin layer of threads remaining in the hole.

Caution!
Be extremely careful not to break a tap or a screw extractor. They are hardened steel and cannot be easily drilled out of a hole. You will compound your problems if you over twist and break one of these tools.

Tech Tip!
If you accidentally break a tap off in a part, screw the broken piece back into the hole until the flutes, or grooves, in the two pieces of the tap align. Next, insert nails or pieces of cotter pin into the grooves and down through both pieces of the tap. You should then be able to unscrew both pieces of the broken tap from the hole. See **Figure 9-20**.

You can now use broken tap to unscrew other piece from hole
Threaded hole in part

Figure 9-20. If you accidentally break a tap, try unscrewing it using nails or cotter pins to hold both pieces of the broken tap together.

Rust Penetrant

Rust penetrant is a chemical that dissolves rust or corrosion. It is often applied to rusted fasteners to aid in their removal. The penetrant is sprayed or squirted on the rusty fastener and allowed to soak for a few minutes. This often helps the fastener free up without breakage. See **Figure 9-21.**

Gaskets and Seals

Gaskets and seals are used between parts to prevent leakage of engine oil, coolant, transmission oil, and other fluids. It is important to understand a few principles about gaskets and seals. If gaskets or seals are serviced improperly, customer complaints and serious mechanical failures can result.

Gaskets

A ***gasket*** is a soft, flexible material placed between parts to prevent leakage. See **Figure 9-22.** It can be made of fiber materials, rubber, neoprene (synthetic rubber), cork, treated paper, or thin steel.

When the parts are fastened tightly together, the gasket is compressed and deformed. This forces the gasket material to fill small gaps, scratches, dents, or other imperfections in the mating surfaces. A leakproof seal is produced.

Gasket Rules

When working with gaskets, remember the following:

- Inspect for leaks before disassembly. If the two parts are leaking, the part surfaces should be inspected closely for problems.
- Be careful not to nick, gouge, or dent mating surfaces while removing parts. The slightest unevenness can cause leakage.
- Clean off old gaskets carefully. All the old gasket material must be scraped or wire brushed from the parts. Use care, especially on aluminum and brass. These soft metals are easily damaged. Use a dull scraper and wire brush lightly.

Figure 9-21. On rusted threads, such as those on this brake bleed screw, use rust penetrant to help ease turning and prevent breakage of the screw. (Fel-Pro Gaskets)

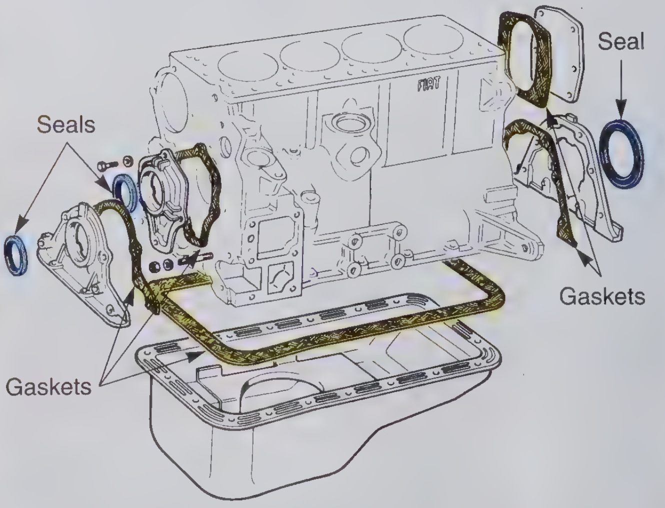

Figure 9-22. Gaskets prevent leakage between stationary parts. Seals prevent leakage between a moving part and a stationary part. (Fiat)

- Wash and dry parts thoroughly using solvent. Blow them dry with compressed air. Then, wipe mating surfaces with a clean shop towel.
- Compare the new gasket to the shape of the mating surface. All holes and sealing surfaces must match perfectly.
- Use sealer if needed! Some gaskets require sealer. Sealer is normally used where two different gaskets come together. It will prevent leakage where gaskets overlap. Check a service manual for details. However, use sealer sparingly. Too much sealer could clog internal passages in the assembly.
- After fitting the gasket and parts in place, screw all bolts in by hand. This will ensure proper part alignment and threading of fasteners. It also lets you check bolt lengths.
- Tighten fasteners in steps! When more than one bolt is used to hold a part, tighten each bolt a little at a time. First, tighten all the bolts to about half of their torque specification. Next, tighten them to three-fourths torque. Then, tighten the fasteners to full torque. As a final precaution, *retorque* each fastener.
- Use a crisscross tightening pattern. Either a basic crisscross or factory-recommended torque pattern should be used when tightening parts. This will ensure even gasket compression and proper sealing.
- Do not overtighten fasteners. It is very easy to tighten the bolts enough to dent sheet metal parts and smash or break the gaskets. Apply only the specified torque.

Tech Tip!
The trend in gasket design is to use large, synthetic-rubber O-ring-type seals instead of fiber or treated paper gaskets. These new seals can be round, D-shaped, or odd-shaped to help seal with the cover design. Follow the manufacturer's instructions when installing these types of gaskets or seals.

Sealers

A gasket is commonly coated with a ***sealer*** to help prevent leakage and to hold the gasket in place during assembly, **Figure 9-23.** There are numerous kinds of sealers. They have different properties and are designed for different uses, **Figure 9-24.** Always read the manufacturer's label and the service manual before selecting a sealer.

Hardening sealers are used on permanent assemblies, such as fittings and threads, and for filling uneven surfaces. They are usually resistant to heat and most chemicals.

Nonhardening sealers are for semipermanent assemblies, such as cover plates, flanges, threads, and hose connections. They are also resistant to most chemicals and moderate heat. ***Shellac*** is a nonhardening sealer. It is a sticky substance that remains pliable. It is frequently used on fiber gaskets as a sealer and to hold the gasket in place during assembly.

Form-in-Place Gaskets

Form-in-place gaskets are special sealers used instead of conventional fiber or rubber gaskets. Two common types of form-in-place gaskets are ***room temperature vulcanizing (RTV) sealer*** and ***anaerobic sealer.***

When selecting a form-in-place gasket, refer to a manufacturer's service manual. Scrape or wire brush all gasket surfaces to remove all loose material. Check that all gasket rails are flat. Using a shop towel and solvent, wipe off oil and grease. The sealing surfaces must be *clean* and *dry* before using a form-in-place gasket.

RTV sealer, also called ***silicone sealer,*** dries in contact with air. It is used to form a rubber-like gasket on thin, flexible flanges. RTV sealer normally comes in a tube, as shown in **Figure 9-25.** Depending on the brand, it can have a shelf life from one year to two years. Always inspect the package for the expiration date before using it. If too old, RTV sealer will *not* cure and seal properly.

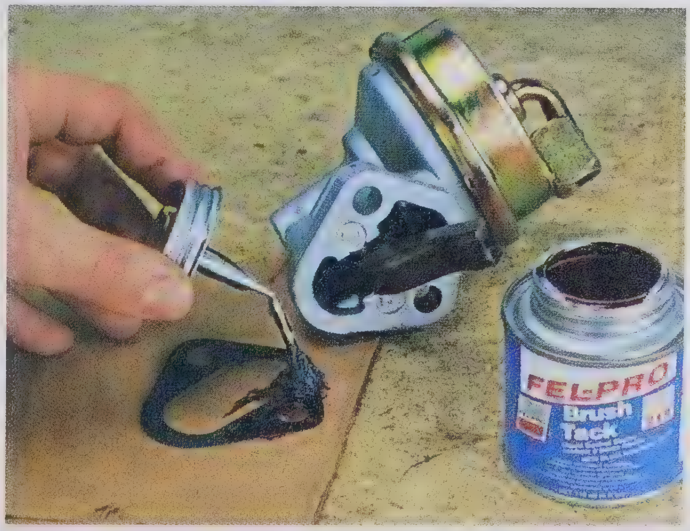

Figure 9-23. Always use the recommended type of sealer or adhesive on gaskets. Some adhesives are oil and fuel soluble and can cause leakage. Both spray adhesive and brush-on sealer are available. They will hold the gasket in place during the assembly of parts. (Fel-Pro)

Type	Temperature range	Use	Resistant to	Characteristics
shellac	–65° to 350° F (–54° to 177° C)	general assembly: gaskets of paper, felt, cardboard, rubber, and metal	gasoline, kerosene, grease, water, oil, and antifreeze mixtures	dries slowly sets pliable alcohol soluble
hardening gasket sealant	–65° to 400° F (–54° to 205° C)	permanent assemblies: fittings, threaded connections, and for filling uneven surfaces	water, kerosene, steam, oil, grease, gasoline, alkali, salt solutions, mild acids, and antifreeze mixture	dries quickly sets hard alcohol soluble
nonhardening gasket sealant	–65° to 400° F (–54° to 205° C)	semipermanent assemblies: cover plates, flanges, threaded assemblies, hose connections, and metal-to-metal assemblies	water, kerosene, steam, oil, grease, gasoline, alkali, salt solutions, mild acids, and antifreeze solutions	dries slowly nonhardening alcohol soluble

Figure 9-24. Different uses and characteristics of various types of sealers. (Fel-Pro)

RTV sealer should be applied in a continuous bead that is approximately 1/8″ (3 mm) wide. All mounting holes must be circled. Locating dowels are often used to prevent the sealing bead from being smeared. If the continuous bead is broken, a leak may result. Uncured RTV can be removed with a rag. Components should be torqued in place while the RTV is still wet to the touch, usually within about 10 minutes of application.

Anaerobic sealer cures to a plastic-like substance in the absence of air and is designed for tightly fitting, thick parts. It is used between two smooth, true surfaces, *not* on thin, flexible flanges. **Figure 9-26** shows the use of both anaerobic sealer and RTV sealer on an engine's front cover. The RTV-sealed section contacts the flexible engine oil pan. The anaerobic-sealed section touches the strong, machined engine block.

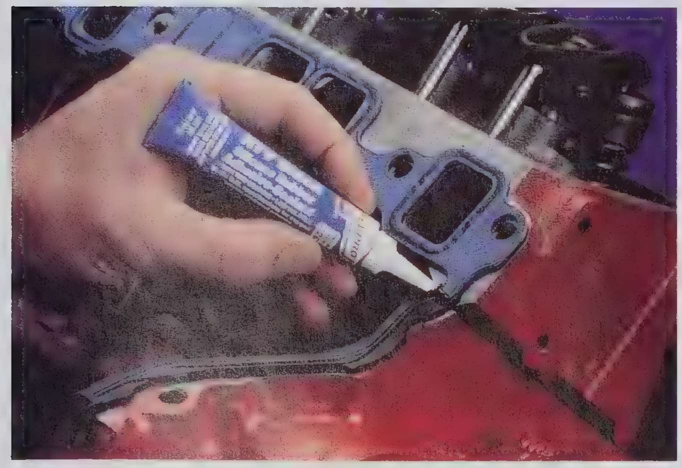

Figure 9-25. RTV sealer is commonly recommended where two different gaskets join. This sealer prevents leakage between the two gaskets.

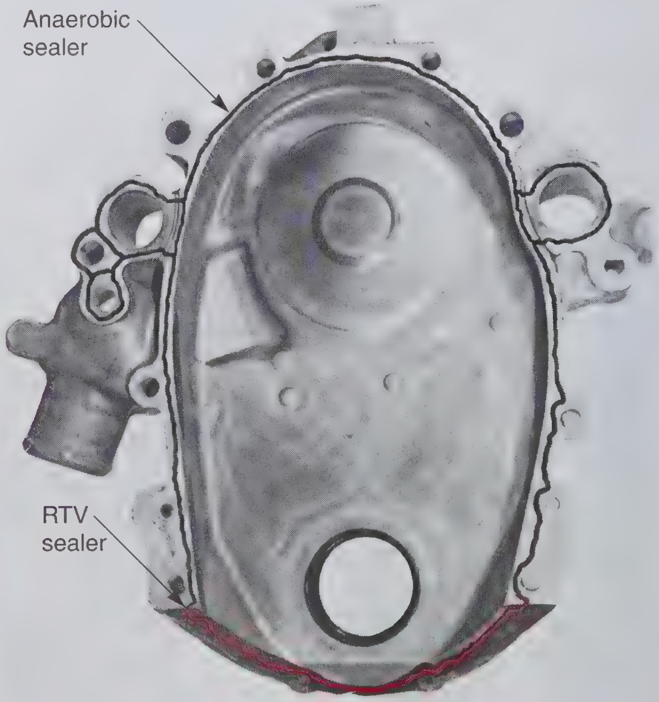

Figure 9-26. Notice the use of both RTV and anaerobic sealers. RTV is for flexible flanges. Anaerobic sealer ~~is for~~ solid, tight-fitting castings. Use the recommended bead size and form a continuous bead to avoid leakage. (Pontiac)

Anaerobic sealer should be applied sparingly. Use a 1/16″–3/32″ (1.5 mm–2 mm) wide bead on one gasket surface. Be certain that the sealer surrounds each mounting hole. Typically, bolts should be torqued within 15 minutes of sealer application.

Tech Tip!
A few gasket manufacturers sell precut gaskets designed to replace form-in-place gaskets. When working on an engine installed in a vehicle, it can be difficult to properly clean the sealing surfaces. It may also be impossible to fit a part on the engine without hitting and breaking the bead of sealant. When this is the case, a precut gasket might work better than a form-in-place gasket.

Seals

Seals prevent leakage between a stationary part and a moving part. They can be found in engines, transmissions, power steering units, and almost any part containing fluid and moving parts. A seal allows a shaft to spin or slide inside a nonmoving part without fluid leakage. Seals are normally made of synthetic rubber molded onto a metal body, **Figure 9-27.**

Seal Rules

There are several important procedures to remember when working with seals.

- Inspect the seal for leakage before disassembly. If a seal is leaking, there may be other problems besides a defective seal. Look for a bent shaft, misaligned seal housing, or damaged parts. Leakage requires close inspection after disassembly.

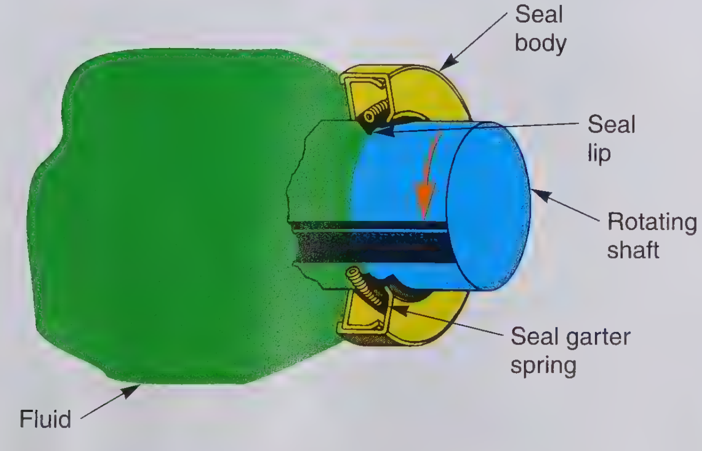

Figure 9-27. A seal mounted in a stationary part. The shaft spins inside the seal. The seal lip faces the fluid and keeps it inside the part. (Caterpillar Tractor)

- Remove the old seal carefully, without scratching the seal housing. Sometimes, a special puller is required for seal removal. This is discussed in later chapters.
- Inspect shafts for wear and burrs, **Figure 9-28.** Look at the shaft closely where it contacts the seal. It should be smooth and flat. File off any burrs that may cut the new seal. A badly worn shaft will require polishing, a shaft sleeve repair kit, or replacement.
- Compare the old seal to the new seal. Hold them next to each other. Both the inside diameter (ID) and the outside diameter (OD) must be the same. To double-check the ID, slip the seal over the shaft. It should fit snugly to prevent leakage.
- Install the new seal correctly. Coat the outside of the seal housing with an approved sealer. Coat the inner lip of the seal with system fluid. Install the seal with the sealing lip facing the *inside* of the part. If installed backwards, a tremendous leak will result. Also, check that the seal is squarely and fully seated in its bore.

O-Ring Seals

An ***O-ring seal*** is a stationary seal that fits into a groove between two parts, **Figure 9-29.** When the parts are assembled, the synthetic rubber seal is partially compressed to form a leakproof joint. Normally, O-ring seals should be coated with system fluid, such as engine oil, diesel fuel, or transmission fluid before installation. This helps the parts slide together without scuffing or cutting the seal. Usually, sealants are *not* used on O-ring type seals. When in doubt about any seal installation, refer to a shop manual.

Figure 9-30 shows a special engine seal that fits into an odd-shaped groove in an engine part. When installing

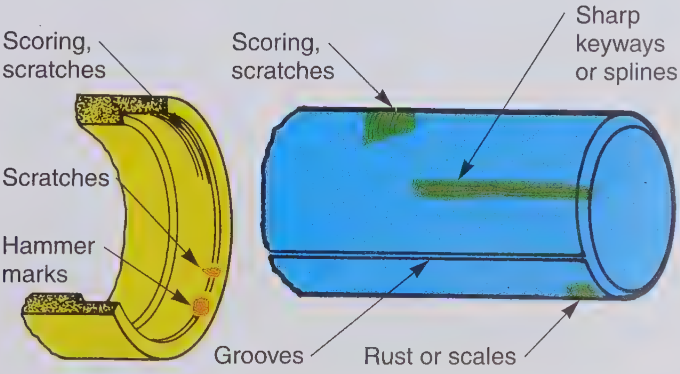

Figure 9-28. Always inspect seals and shafts for damage. Slight nicks or scratches could cause leakage. (Federal Mogul)

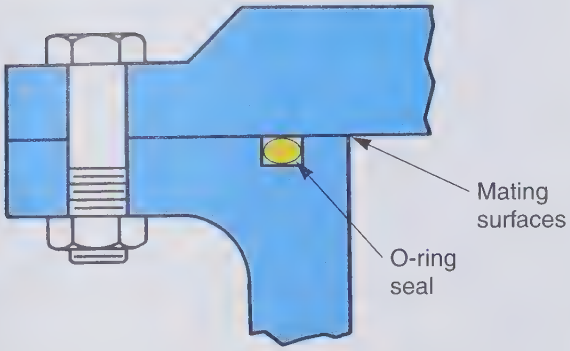

Figure 9-29. O-ring seals prevent leakage by applying pressure to multiple surfaces, as shown. When the parts are bolted together, they partially compress the O-ring. (Deere & Co.)

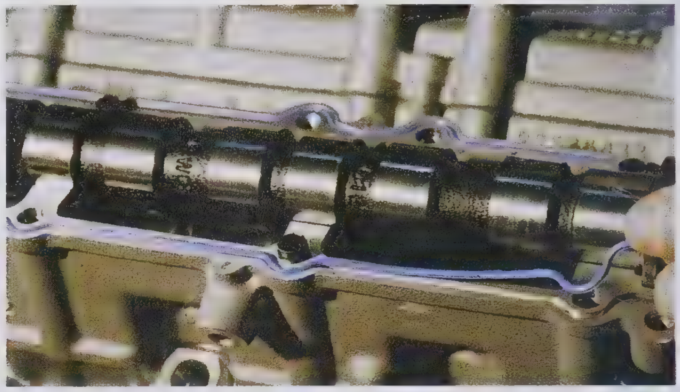

Figure 9-30. Many modern engines use synthetic seals instead of gaskets. This specially shaped seal fits down into a groove formed in the part.

this type seal, make sure the part groove is perfectly clean. During assembly, make sure the seal does not fall out of its groove, or leakage will result.

Other Information

Special gaskets and seals sometimes require other installation techniques. These special situations are discussed in later chapters.

Workplace Skills

One of the most serious and common mistakes in automotive service is not torquing wheel lug nuts properly. Improper wheel lug nut torque can warp the brake rotor or wheel, or allow the wheel nuts to loosen, which can lead to a very dangerous situation. To torque wheel lug nuts correctly, run the lug nuts down lightly with an air impact wrench and then tighten them to factory specifications with a torque wrench. If tightening the lug nuts in this way prevents even one problem, it was worth the extra time to do the job right.

Summary

- Fasteners are devices that hold the parts of a vehicle together.
- When a high-quality bolt is threaded into a part without a nut, it can also be called a cap screw.
- Bolt size is a measurement of the outside diameter of the bolt threads.
- Tensile strength, or grade, refers to the amount of pull or stretch a fastener can withstand before breaking.
- A flat washer increases the clamping surface under the fastener.
- A lock washer prevents the bolt or nut from becoming loose under stress and vibration.
- It is very important that bolts and nuts are torqued properly.
- Torque specifications are tightening values given by the vehicle manufacturer.
- Generally, tightening a group of fasteners on a part follows a crisscross pattern.
- A torque wrench measures the twisting force applied when tightening a threaded fastener.
- A tap is a threaded tool for cutting internal threads in holes. A die cuts external threads.
- Machine screws are similar to bolts, but they normally have screwdriver type heads.
- Numerous types of nonthreaded fasteners, such as snap rings, clips, and adhesives, are utilized in the assembly of a vehicle.
- Adhesives are widely used on most vehicles.
- A gasket is a soft, flexible material placed between parts to prevent leakage.
- RTV sealer, also called silicone sealer, cures in the presence of air. It is used to form a rubber-like gasket on thin, flexible flanges.
- Seals prevent leakage between a stationary part and a moving part.

Important Terms

- Fasteners
- Bolt
- Cap screw

- Sealer
- Seals

Review Questions—Chapter 9

Please do not write in this text. Place your answers on a separate sheet of paper.

1. Define the terms *bolt* and *nut*.
2. How are bolts and nuts usually named in automotive terminology?
3. List and explain the four basic dimensions of a bolt.
4. Customary bolt heads are marked with _____ or _____ marks to indicate bolt strength. Metric bolts use a _____ system to indicate bolt strength.
5. A(n) _____ _____ is a safety device commonly used with a slotted nut.
6. Describe the difference between a flat washer and a lock washer.
7. What are torque specifications?
8. What is a bolt or nut tightening sequence?
9. Which of the following is *not* used for thread repair?
   (A) Tap.
   (B) Die.
   (C) Chaser.
   (D) Chisel.
10. A _____ and _____ _____ _____ is needed to select the right size drill and tap.
11. How do you use a thread repair insert?
12. Describe six ways to remove broken fasteners.
13. Which of the following group of sealers is used on permanent assemblies?
   (A) Hardening.
   (B) Nonhardening.
   (C) Form-in-place.
   (D) All the above.
14. Explain when RTV and anaerobic sealers are recommended.
15. Describe five rules for working with seals.

ASE-Type Questions

1. When rebuilding a steering system, a can of bolts and nuts was somehow lost. Technician A says to simply go to the hardware store and buy the same size fasteners. Technician B says to order the fasteners from the manufacturer. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Which of the following is a safety device that keeps a slotted nut from turning or coming off?
   (A) Lock tab.
   (B) Snap ring.
   (C) Cotter pin.
   (D) Thread pitch.
3. Which of the following is determined by measuring bolt length change while torquing a bolt?
   (A) Torque stretch.
   (B) Torque-to-yield.
   (C) Torquing sequence.
   (D) Torque specification.
4. Fastener tightening generally follows a:
   (A) clockwise pattern.
   (B) crisscross pattern.
   (C) left-to-right pattern.
   (D) counterclockwise pattern.
5. Which of the following is *not* a basic rule to follow when using a torque wrench?
   (A) Avoid using swivel joints.
   (B) Pull only on the wrench handle.
   (C) Clean fastener threads.
   (D) Use short, jerky pull motions for accuracy.

6. Which threaded tool is used for cutting internal threads in holes?
   - *(A) Tap.*
   - *(B) Helicoil.*
   - *(C) Thread chaser.*
   - *(D) Thread repair insert.*
7. Each of the following is a tool that can be used to help remove problem fasteners *except:*
   - *(A) hacksaw.*
   - *(B) stud puller.*
   - *(C) die.*
   - *(D) screwdriver.*
8. Snap rings hold and fit into grooves in:
   - *(A) pins.*
   - *(B) gears.*
   - *(C) shafts.*
   - *(D) All the above.*
9. Set screws are headless fasteners designed to accept a(n):
   - *(A) hex wrench.*
   - *(B) screwdriver.*
   - *(C) Allen wrench.*
   - *(D) All the above.*
10. While installing gaskets, Technician A believes gaskets alone will produce leakproof seals. Technician B believes that some gaskets require sealer to further prevent leakage where gaskets overlap. Who is right?
   - *(A) A only.*
   - *(B) B only.*
   - *(C) Both A and B.*
   - *(D) Neither A nor B.*

Activities for Chapter 9

1. Prepare a large chart for the shop showing how to read information given on a bolt.
2. Demonstrate the proper methods for repairing thread damage.

10

Vehicle Maintenance, Fluid Service, and Recycling

After studying this chapter, you will be able to:

- Check a car's fluid levels.
- Explain the importance of vehicle maintenance.
- Locate fluid leaks.
- Replace engine oil and filter.
- Change automatic transmission fluid and filter.
- Perform a grease job.
- Inspect for general problems with hoses, belts, and other components.
- Demonstrate safe practices while working with vehicle fluids.
- Correctly answer ASE certification test questions on fluid service and vehicle maintenance.

Vehicle fluids include engine oil, coolant, brake fluid, transmission fluid, power steering fluid, and other liquids. All automotive technicians will, at some time, service vehicle fluids. Service station attendants, apprentices, and even experienced technicians must check, add, or replace fluids.

Many technicians' first job is as a service station attendant. They "cut their teeth" doing fluid service, grease jobs, and light mechanical repairs. Therefore, this chapter is extremely important. It is your chance to learn fluid service and prepare for what may be your first job. Study this material carefully.

The last section of the chapter discusses recycling. To help save our environment, you should recycle as many automotive parts and materials as possible. Plastic bumpers, batteries, tires, and used fluids can all be recycled into new products. Find recyclers in your area who can take your used parts and make them into new products. This will help prevent larger landfills. It will also save energy because less energy is often needed to manufacture new products from recycled ones.

Lubrication Service

Lubrication service is vital to keeping a vehicle in good working order. A technician must be familiar with all aspects of lubrication service, which include:

- Checking fluid levels and conditions.
- Adding fluids as needed.
- Changing engine oil and filter.
- Changing automatic transmission fluid.
- Lubricating (greasing) certain chassis parts.
- Locating fluid leaks and other obvious problems.
- Following state regulations for recycling and disposal of fluids.

Vehicle Maintenance

Vehicle maintenance includes any operation that will keep a vehicle in good operating condition. Without proper care, the life of an automobile may be reduced by thousands of miles. For example, fluids can become contaminated and change chemically after prolonged use. This can cause wear, corrosion, and mechanical failure of parts.

Tech Tip!
A wise saying goes, "You can pay now or you can pay later." In the automotive field, this means that the customers can pay a little now for maintenance or pay much more later for repairs. A poorly serviced vehicle will wear out and break down sooner than a well-maintained vehicle. In the long run, vehicle maintenance saves the customer money.

Fluid Service

A service manual contains detailed information on how to check fluid levels. The manual will usually describe:

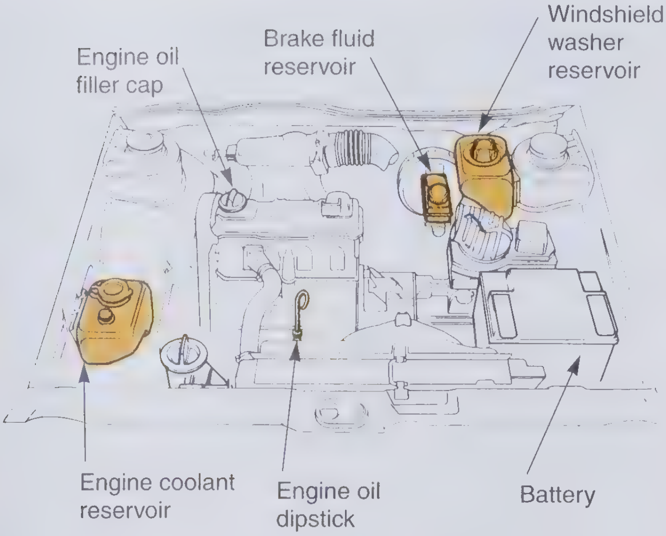

Figure 10-1. A service manual gives the locations of all fluid checkpoints. This manual illustration shows engine compartment fluid check points. (VW)

- Location of fluid check points, **Figure 10-1.**
- Location of fluid fill points.
- Correct interval (time or mileage) between fluid checks and changes.
- Correct type and quantity of fluid to be used.

This information varies from vehicle to vehicle. For example, a diesel engine may require more frequent oil changes than a gasoline engine. Automatic transmission or transaxle fluids, differential lubricants, and other fluids can vary in chemical content.

Tech Tip!

A car's warranty may become void if incompatible fluids, incorrect service procedures, or improper intervals are used. For this reason, refer to the manufacturer's recommendations when servicing fluids.

Fluid capacity is the maximum amount of fluid a reservoir or assembly will hold. The vehicle manufacturer will list fluid capacities for the engine, transmission/transaxle, and other components or systems.

Checking Engine Oil

To check engine oil, warm the engine to operating temperature. Shut off the engine and allow it to sit for a few minutes. Locate and remove the engine oil dipstick. Wipe off the dipstick and replace it all the way into its tube. Pull the dipstick back out and hold it over your shop rag. See **Figure 10-2.**

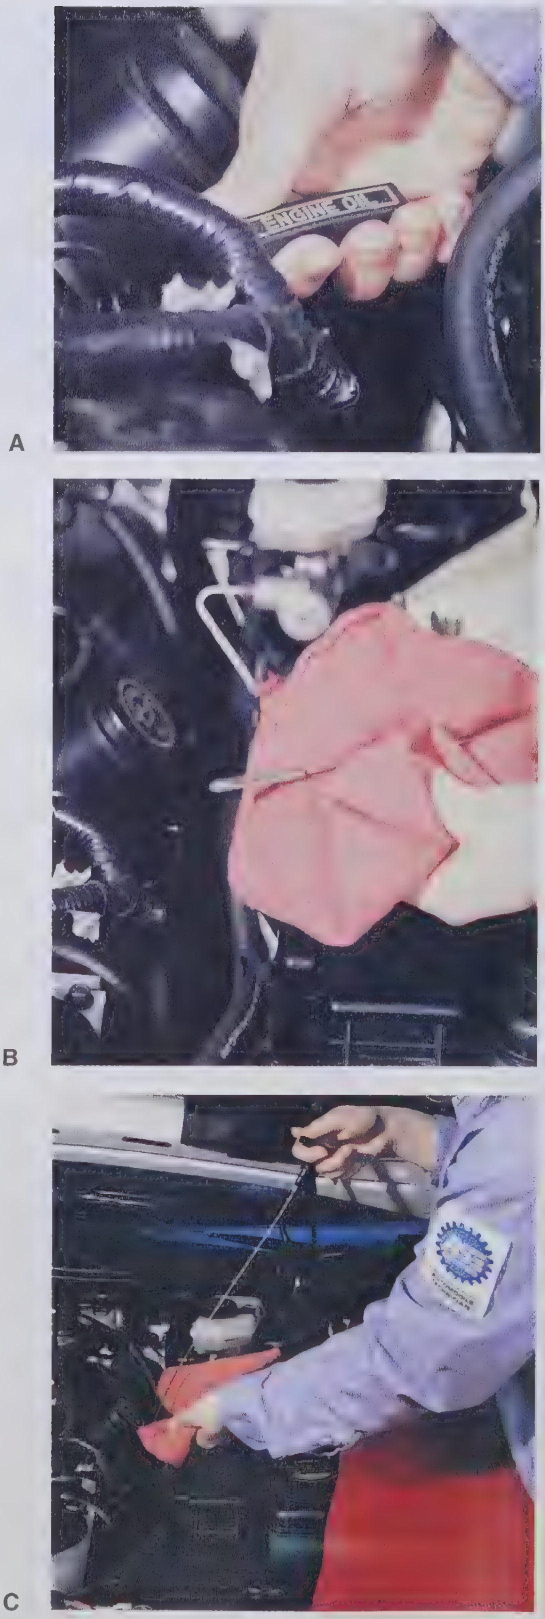

Figure 10-2. Check the amount of oil in the engine using the dipstick. A—Locate the dipstick and remove it from the engine. B—Wipe the oil from the dipstick; then reinsert the dipstick in its tube. C—Remove the dipstick and check the oil level. Hold the dipstick over a shop rag to prevent oil from dripping onto the engine or the shop floor.

As shown in **Figure 10-3,** the oil level should be between the ADD (LOW) and FULL marks on the dipstick. Before reinstalling the dipstick, inspect the condition of the oil. The oil should not be too thick or thin, smell like gasoline, or be too dirty.

Warning!
Be careful when checking or changing vehicle fluids. At operating temperature, oil and other fluids can be hot enough to burn your hand.

If the oil level is low, you must add the correct amount and type of oil. If the oil level is down to the ADD mark, typically one quart is needed. If the dipstick reads halfway between ADD and FULL, you would need to add only one-half quart.

Never add too much oil to an engine. Pour in only enough oil to reach the FULL mark. Overfilling can cause ***oil foaming*** (the oil absorbs air bubbles), which reduces the oil's lubricating ability.

Adding engine oil

To add engine oil, obtain the right kind of oil. Look for a lubrication sticker in the engine compartment or on the driver's door. Use the same type of oil that was installed during the last oil change, if possible.

To add oil to the engine, remove the oil cap, which is usually on the valve cover. Install a small, clean funnel into the engine opening. Without spilling, pour the oil slowly into the funnel and engine filler tube or opening.

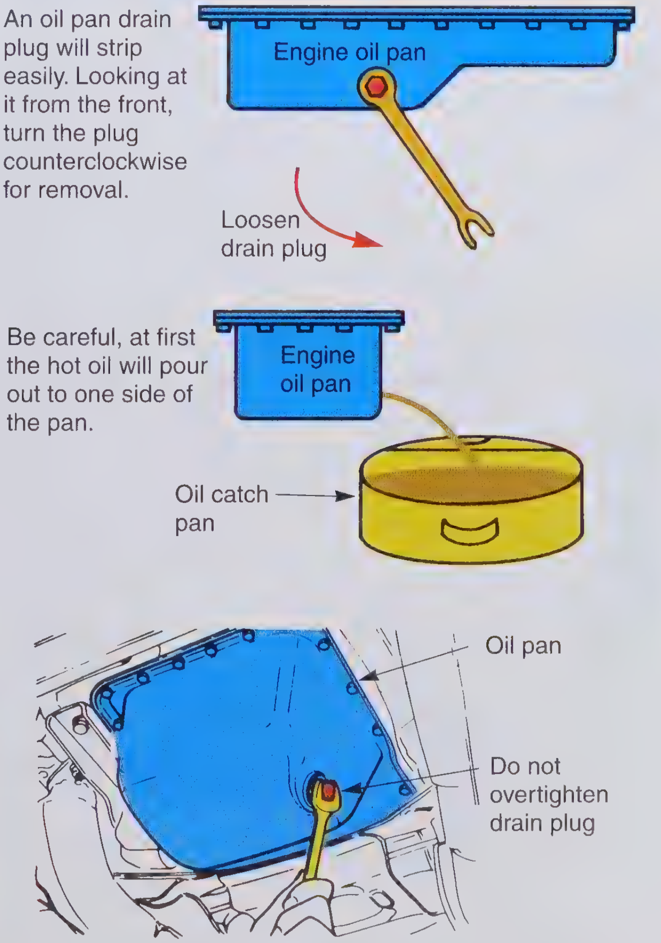
Changing Engine Oil and Filter

When changing engine oil, make sure the engine is warm and the vehicle is sitting level. This will ensure that more of the oil contaminants are suspended in the oil and are drained out of the engine. If the oil is cold, the oil will drain more slowly and debris will settle to the bottom of the oil pan.

Figure 10-3. Oil should be between the ADD and FULL marks. Be sure to check the condition of the oil before reinserting the dipstick.

To change the engine oil:

1. Warm up the engine.
2. Raise the car on a lift or place it on jack stands in a level position.
3. Place a catch pan under the oil drain plug.
4. Unscrew the plug and allow enough time for the oil to drain completely. See **Figure 10-4.**
5. Reinstall the drain plug. Be careful. The threads in the pan and on the plug can strip easily. Apply only enough torque to draw the plug tight and prevent leakage. A ***stripped oil drain plug*** can damage the oil pan threads.
6. Position your catch pan under the oil filter.
7. Using an oil filter wrench, as in **Figure 10-5,** unscrew the filter.



An oil pan drain plug will strip easily. Looking at it from the front, turn the plug counterclockwise for removal.
Engine oil pan
Loosen drain plug
Be careful, at first the hot oil will pour out to one side of the pan.
Engine oil pan
Oil catch pan
Oil pan
Do not overtighten drain plug

Figure 10-4. To drain the engine oil, remove the oil pan drain plug. Allow the oil to pour into a catch pan. Be careful not to overtighten the drain plug. Its threads will strip out easily. (Subaru)

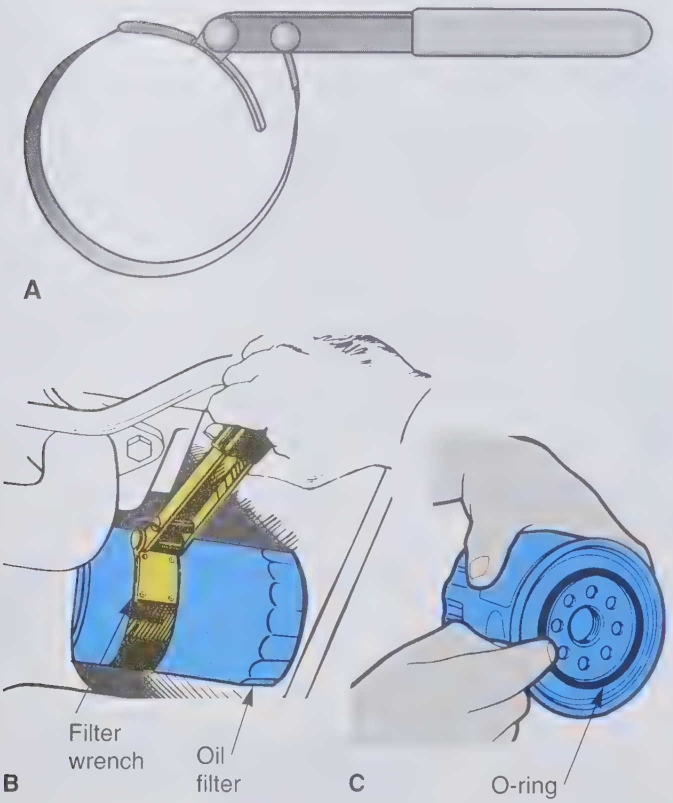


Figure 10-5. Changing the engine oil filter. A—An oil filter wrench is needed to unscrew the oil filter. B—Turn in a counterclockwise direction. C—When installing a new filter, coat the O-ring seal with clean oil and only hand tighten the filter. (Lisle)

8. Obtain the correct replacement filter. Compare the old and new filters. Make sure the rubber O-ring on the new filter has the same diameter as the O-ring on the old filter.
9. Wipe some clean oil on the O-ring and install the new filter.
10. Tighten the filter by hand only, *not* with the filter wrench. Overtightening will smash the O-ring and cause leakage.
11. Lower the car to the ground and add the correct amount and type of oil.
12. Start the engine and make sure the oil pressure light *goes out*.
13. Let the engine run while checking for leaks under the engine.
14. Shut off the engine and check the oil level again.

Automatic Transmission/Transaxle Fluid and Filter Service

Like engine oil, automatic transmission and transaxle fluid should be checked and changed at specified intervals. The fluid can become contaminated (filled) with metal, dirt, moisture, and friction material (nonmetallic, heat-resistant fibrous substance) from internal parts. This can cause rapid part wear and premature transmission failure.

To check the fluid in an automatic transmission or transaxle, warm up the engine and move the gear selector through all positions. Apply the parking brake. Place the transmission in park and block the wheels.

With the engine still running, locate the transmission dipstick. See **Figure 10-6.** It is normally behind the engine, near the front of the transmission.

Tech Tip!
Don't "go crazy" looking for the transmission dipstick on some new cars and trucks. You may not find one. Some transmissions and transaxles are sealed at the factory. They are designed to not require fluid changes and periodic checking of fluid level.

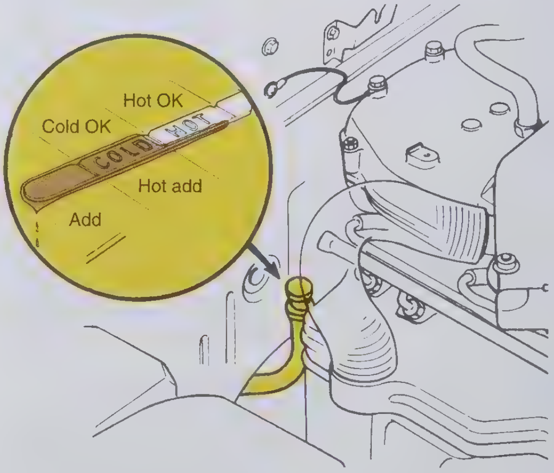

Figure 10-6. An automatic transmission fluid dipstick is normally behind engine, on the side. Check it with the engine running and the transmission in park. If needed, add the correct fluid. (Saab)

Pull out the dipstick. Wipe it off and reinsert it into the tube. Remove the dipstick again and hold it over a shop rag. The fluid should read between the ADD and FULL marks. Also, inspect the fluid for discoloration and odor. If it smells burned or looks dirty, the fluid should be changed.

It is very easy to overfill an automatic transmission. Seldom do you have to add a full quart. Normally, if the dipstick reads ADD, only a fraction of a quart is needed to fill the transmission. Sometimes, instructions are written on the dipstick. If in doubt, check a shop manual.

To change the fluid and filter in an automatic transmission or transaxle:

1. Warm the engine and transmission or transaxle.
2. Raise the vehicle.
3. Remove all but one of the bolts securing the transmission pan, **Figure 10-7.** Be careful not to spill the hot transmission fluid. It can cause painful burns!
4. Loosen but do not remove the last pan bolt while holding the pan in place with a shop rag.
5. Allow the pan to drop and let the fluid pour into a catch pan.
6. Unscrew the last pan bolt and remove the pan. If needed, replace or clean the transmission filter, **Figure 10-8.**
7. Scrape the old gasket off the transmission pan and housing.
8. Position the new pan gasket using an approved sealer. Use the sealer sparingly. You do not want any to squeeze out of the gasket and into the transmission or transaxle housing.
9. Start all the pan bolts with your fingers.
10. Tighten the pan bolts in a crisscross pattern to their recommended torque specification. Overtightening can split the gasket or distort the transmission pan.
11. If recommended, drain the torque converter (fluid coupling in front of the transmission). A drain plug may be located in the converter. It is usually under a rock shield on the front of the transmission housing.
12. Refill the transmission with the correct type and amount of transmission fluid. If required, check a service manual for details. In most cases, you must pour fresh fluid into the dipstick tube.
13. Start the engine and shift through the gears.
14. Check under the car for leaks and check the fluid level.

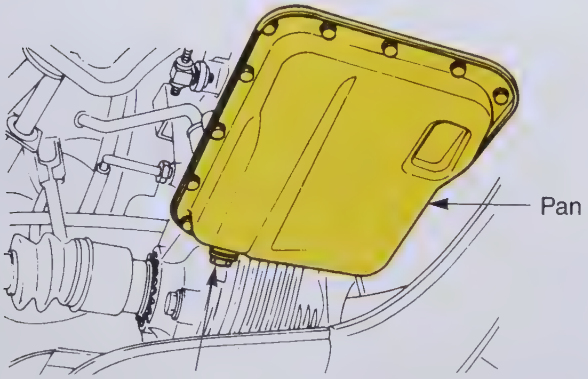

Figure 10-7. Usually, the transmission pan must be removed to drain the fluid. A few pans, however, have a drain plug. Do not spill hot fluid on yourself. (Subaru)

Manual Transmission Fluid Service

To check the fluid in a manual transmission, locate and remove the transmission fill plug, **Figure 10-9.** It is normally on one side of the transmission. Generally, warm fluid should be even with the fill hole. With the transmission cold, the fluid can be slightly below the fill hole.

Some manufacturers suggest that manual transmission fluid be changed periodically; others do not. If a fluid

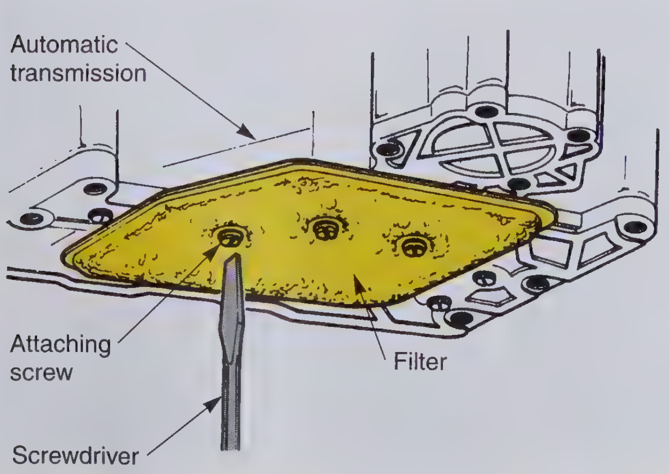

Figure 10-8. Some manufacturers recommend periodic replacement of the automatic transmission filter. It is located inside the transmission pan. Tighten all fasteners to specs when assembling.

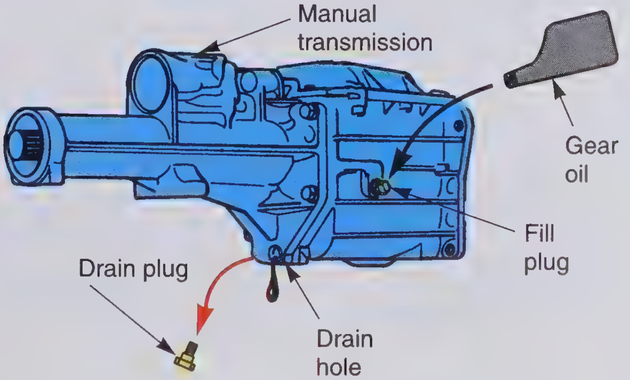

Figure 10-9. A manual transmission will have a fill plug for checking the fluid level. The fluid should be almost even with the hole when the fluid is warm. Check the service manual for details. (DaimlerChrysler)

change is needed, remove the drain plug on the bottom of the transmission case and allow all the fluid to pour into your catch pan. Replace the drain plug and install the right type and quantity of fluid. Lubricate the gear shift mechanism and clutch release as described in a service manual.

Some new transmissions and transaxles are designed to *never* need fluid replacement with normal use. They are permanently sealed. The chemical makeup of the fluid, improved filtering, and less part wear have allowed this technological advance.

Differential Fluid Service

To measure the fluid level in a differential (rear axle assembly), remove the fill plug. It will normally be on the front, back, or side of the differential. See **Figure 10-10.** The lubricant should be even with the fill hole when hot. When cold, it should be slightly below the hole.

At the manufacturer's recommended change interval, remove the drain plug. It will be on the bottom of the differential. After draining, reinstall the plug and fill the differential with the proper lubricant. If a drain plug is not provided, a special siphon (suction) gun can be used to draw out the old fluid.

Caution!
Positive-traction, or limited-slip, differentials (both wheels turn for added traction) often require a special lubricant. Refer to the vehicle identification number, a service manual, and Chapter 62, *Differential and Rear-Drive Axle Diagnosis and Repair,* for details. If you install the wrong lubricant, differential action and traction can be adversely affected.

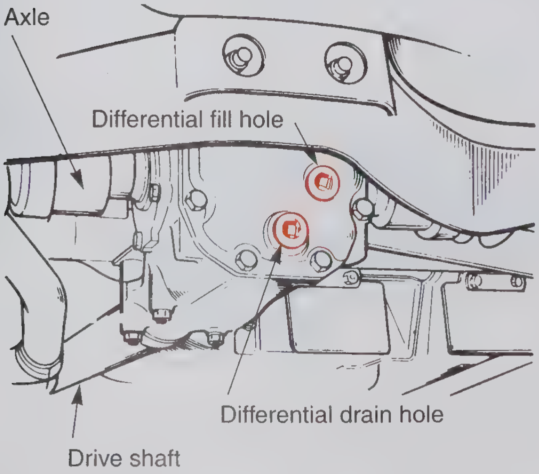

Figure 10-10. The differential fill hole allows for a check of the lubricant level. Do not accidentally remove the drain plug. (Subaru)

Checking Engine Coolant

Engine coolant (mixture of water and antifreeze) is used in an engine's cooling system. Engine coolant must be changed periodically. After prolonged use, the coolant will deteriorate. It can become very corrosive and filled with rust. This may result in premature water pump, thermostat, and radiator failure.

Warning!
Never remove a radiator cap while the engine or radiator is hot. Boiling coolant can spray out of the radiator, causing serious burns.

To check the coolant level, look at the side of the plastic overflow tank connected to the radiator. See **Figure 10-11.** The coolant should be between the hot and cold marks on the side of the tank. When an overflow tank is used, the radiator cap does *not* need to be removed to check coolant level.

Some older cars do not use an overflow tank. In this case, the radiator cap must be removed to check the coolant level. The coolant should be about an inch (25 mm) down in the radiator. Also, inspect the condition of the coolant, **Figure 10-12.** If rusty, the coolant should be drained and replaced. Watch for system leaks.

Checking Power Steering Fluid

Power steering fluid level should be checked regularly. The engine should not be running when checking power steering fluid. If the fluid is contained in a clear plastic reservoir, simply compare the fluid level to the markings on the side of the reservoir. See **Figure 10-13A.**

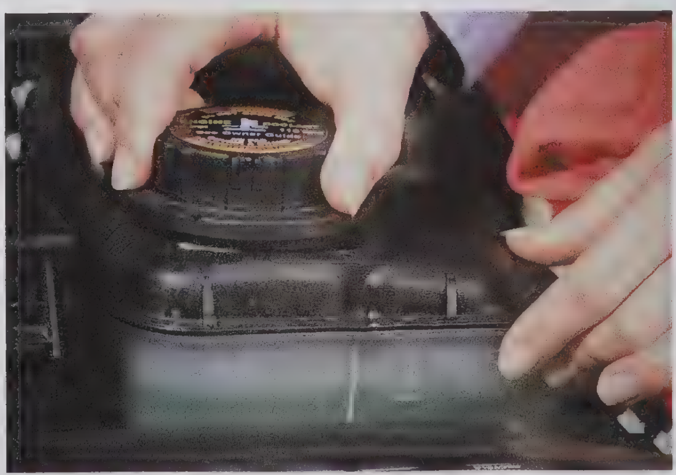

Figure 10-11. Modern cooling systems have a reservoir tank. You can check the coolant level without removing the radiator cap. On older systems, remove the cap only after the engine has cooled.

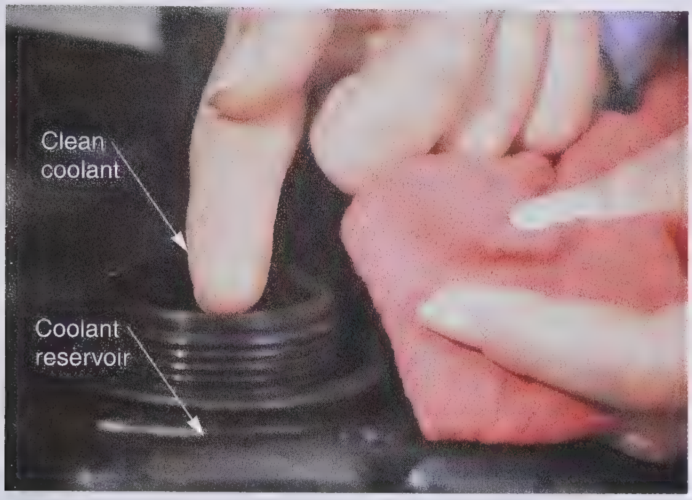

Figure 10-12. Check the condition of the coolant in the reservoir or the radiator. If the coolant is rusty, it should be drained and replaced.

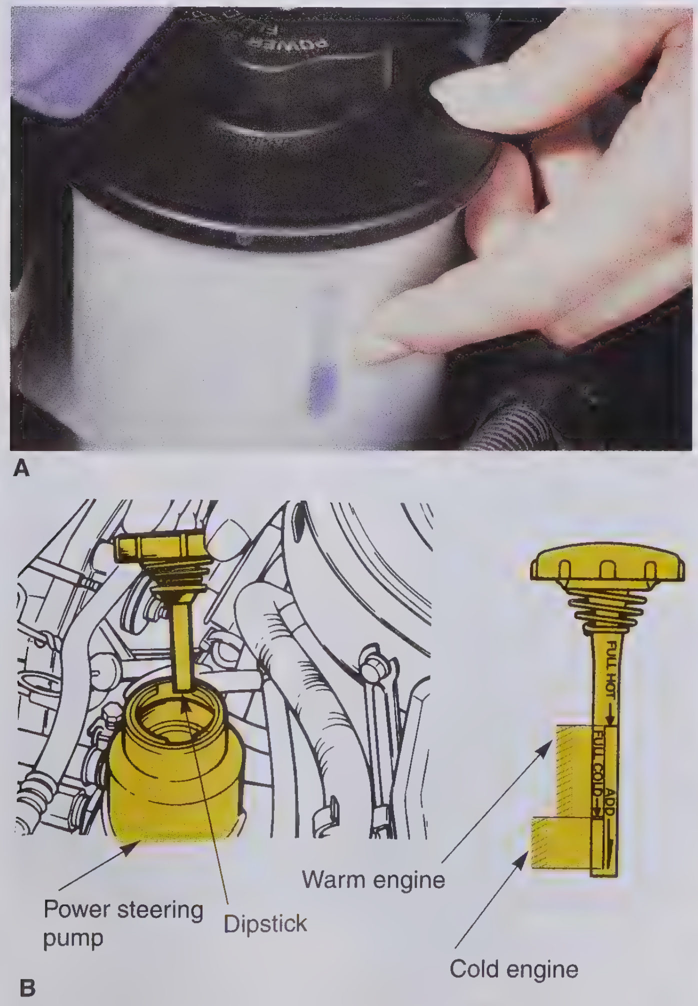

Figure 10-13. Checking power steering fluid. A—Comparing the fluid level to markings on the side of the reservoir. B—On some vehicles, the power steering pump has a cap with a dipstick. Check the fluid with the engine off. Compare the fluid level to markings on the dipstick. (Subaru)

In some vehicles, the level is checked by removing a dipstick from the power steering pump, **Figure 10-13B.** Check the fluid level on the dipstick. If low, inspect for leaks and add the correct type and amount of power steering fluid.

Checking Brake Fluid

The amount of brake fluid in a master cylinder should be inspected at least twice a year. Look at **Figure 10-14.** The master cylinder is normally mounted on the firewall (body section between the engine and the passenger compartment).

When the master cylinder reservoir is clear plastic, simply compare the fluid level to the markings on the reservoir. The fluid should be between the ADD and FULL marks.

With many master cylinders, you must remove the reservoir cover to check the fluid. Generally, the fluid should be about 1/4″ (about 6 mm) down from the top of the master cylinder. Add the recommended type of brake fluid as needed.

Caution!
Never let anything (oil, grease, dirt) contaminate the brake fluid. Oil and grease, for example, will attack the rubber parts in the brake system. Major repairs would be needed and the vehicle could lose braking ability.

Checking Hydraulic Clutch Fluid

Some manual transmission clutches do *not* use mechanical linkage rods or cables. Instead, they use a

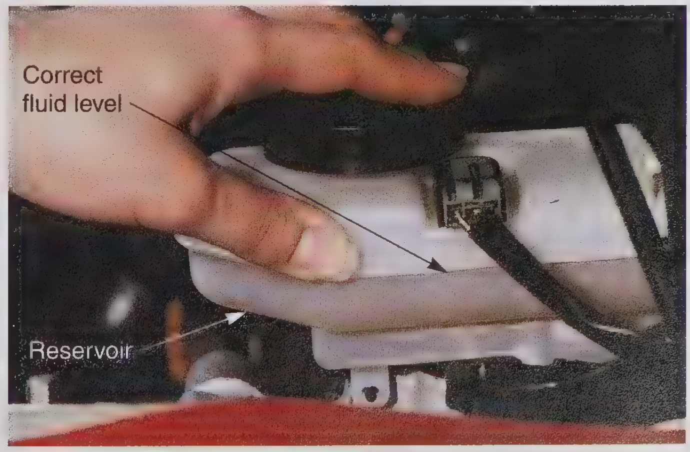

Figure 10-14. Check the brake fluid at the master cylinder reservoir. The master cylinder is mounted on the firewall, in front of the driver. The maximum fluid level is often indicated on the side of the reservoir. If not, fluid should be slightly below the the top of the reservoir.

hydraulic system to disengage the clutch. A clutch master cylinder, similar to a brake master cylinder, produces hydraulic pressure to activate the clutch release. The fluid in the clutch master cylinder should be checked. If low, add brake fluid to fill the reservoir almost full. Always watch for leaks.

Checking Manual Steering Box Fluid

Manual steering box fluid is checked by removing either a fill plug or designated bolt from the top of the box. See **Figure 10-15.** The lubricant should be almost even with the plug or bolt opening. If not, add the recommended fluid.

Checking Windshield Washer Solvent

The windshield washer solution is normally visible through the side of the plastic storage tank. Refer back to **Figure 10-1.** If low, add an approved washer solution. The solution will aid windshield cleaning and also prevent ice formation in cold weather.

Checking Battery

New cars use maintenance-free batteries, which do not require an electrolyte (acid) check. However, make sure that the battery terminals and case top are clean. A battery post and cable cleaning tool can be used on corroded connections. If the top of the battery is dirty, it can be cleaned with a solution of baking soda and water. See **Figure 10-16.**

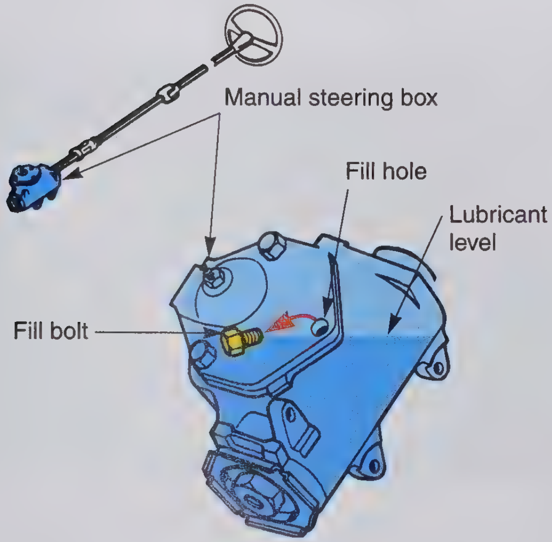

Figure 10-15. The manual steering box will have a bolt or plug for checking the lubricant. If needed, fill with recommended type of fluid up to the fill hole. (DaimlerChrysler)

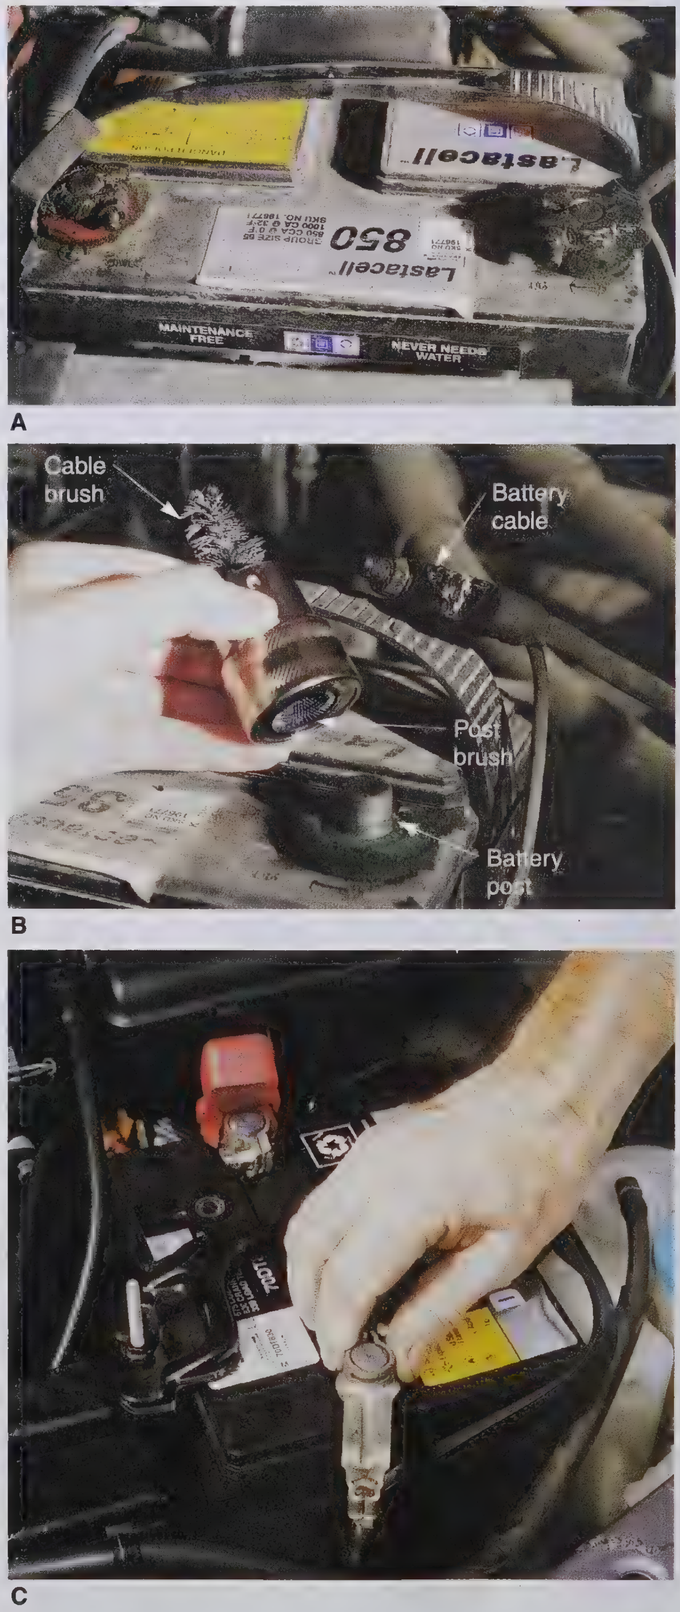

Figure 10-16. Checking battery condition is important to vehicle maintenance. Battery problems are the number one cause of engine “no start” problems. A—A dirty battery top will drain the battery. Corroded terminals prevent charging and starting. B—A post cleaning tool will remove corrosion from the surfaces of posts and cable ends. C—Wash the top of the battery with baking soda and secure terminals.

Filter Service

Quite often, various filters used in a vehicle are replaced during lubrication service. Besides the engine oil and transmission filters, the technician may need to change or clean the air and fuel filters.

If an air filter is extremely dirty, it is normally replaced. However, some manufacturers permit light dirt and dust to be blown from the filter. Special foam or oil-bath (oil-filled) air filters can be cleaned as described in a service manual.

Fuel filters can be located almost anywhere in the fuel circuit. Modern fuel systems often use inline fuel filters between the fuel tank and the engine. In older systems, the fuel filter can be located at the inlet to the throttle body injector or in the carburetor. Most fuel systems also have a fuel strainer on the pickup tube in the fuel tank. Refer to the service manual for exact filter locations.

Warning!
Hold a shop rag around fuel line fittings when loosening. This will keep fuel from spraying out, preventing a possible explosion and fire.

Chassis Lubrication

Chassis lubrication generally involves greasing high-friction points on the vehicle. It may also involve lubricating locks, hinges, latches, and other body parts. Chassis lubrication is often done when the engine oil and filter are serviced.

Grease Job

During a ***grease job***, you must lubricate high-friction pivot points on the suspension, steering, and drive train systems. Most service manuals illustrate which parts must be lubricated, **Figure 10-17.**

A ***grease gun***, **Figure 10-18,** is used to force lubricant (chassis grease) into small fittings. Inject only enough grease to fill the cavity in the part. Overgreasing can sometimes rupture the rubber boot surrounding the joint.

Body Lubrication

When performing a complete chassis lubrication job, you should also lubricate high-friction points on the body (hinges and latches on doors, hood, and trunk). See **Figure 10-19.** This will help prevent squeaking doors, sticking hinges, and wear problems.

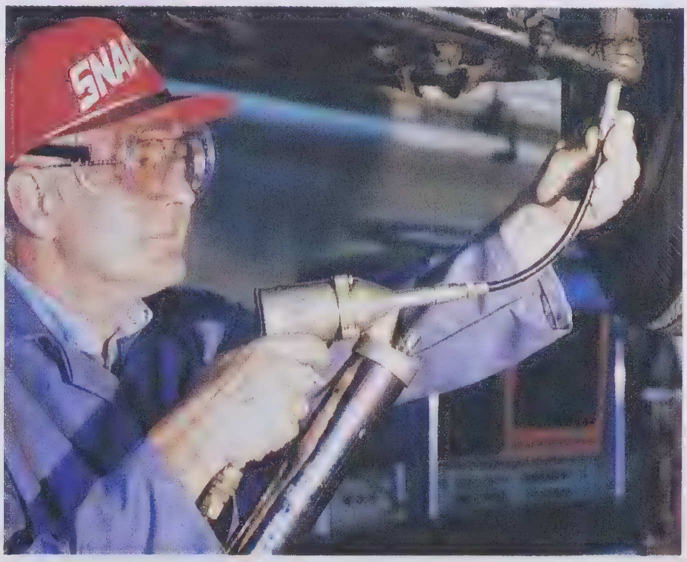

Figure 10-18. This technician is using a power grease gun to lubricate fittings on a suspension system.

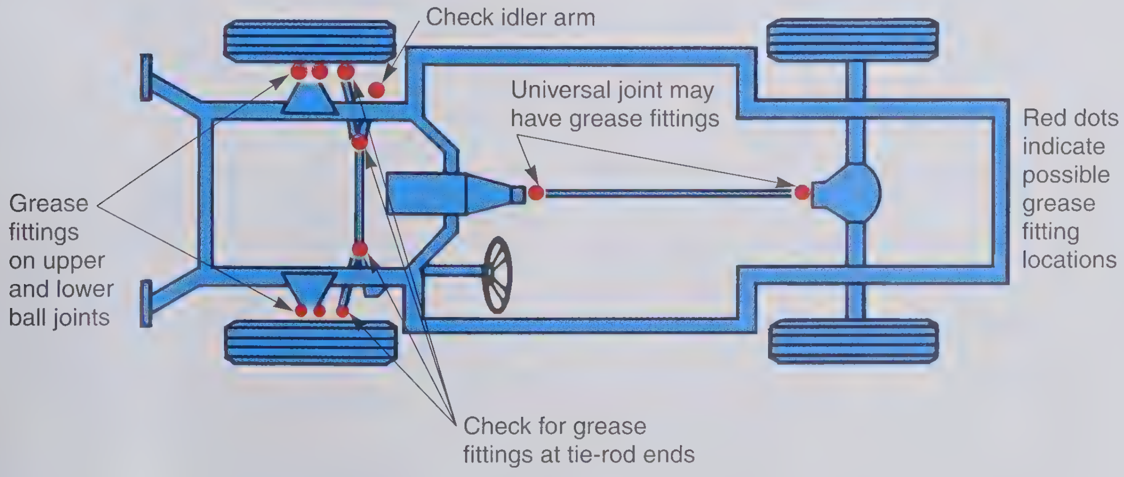

Check idler arm
Universal joint may have grease fittings
Red dots indicate possible grease fitting locations
Grease fittings on upper and lower ball joints
Check for grease fittings at tie-rod ends

Figure 10-17. A grease job involves lubricating the pivot points shown. Some cars have more grease fittings than others. Check closely.

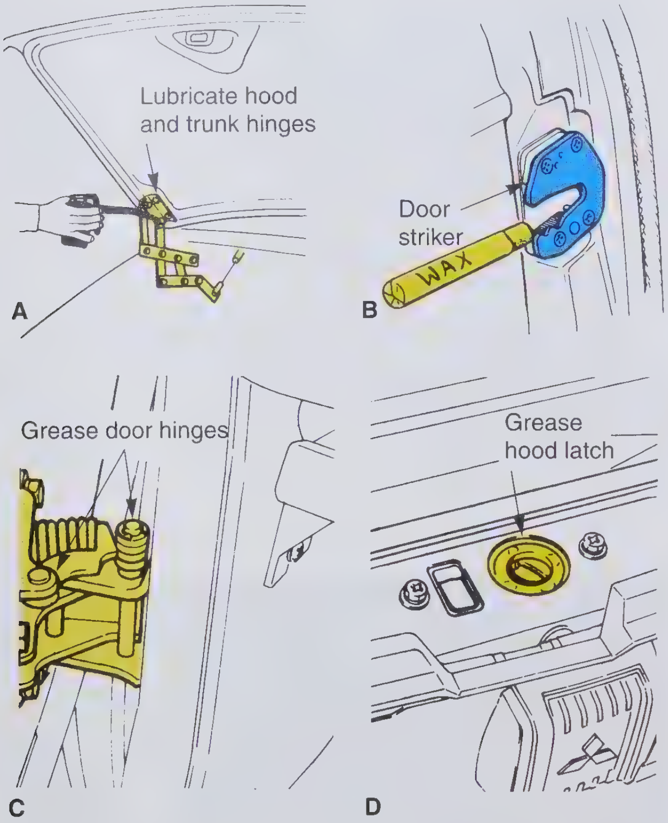

Fig. 10-19. During lubrication service, lubricate body components to prevent squeaks and wear. A—Lubricating hood and trunk hinges. B—Using wax on door strikers. C—Place a dab of grease on door hinges. D—The hood latch is a common rust problem. (Volvo)

Be careful to always use the prescribed lubricant. Normally, rubber and plastic parts will deteriorate if exposed to petroleum-based lubricants (oils and grease). Silicone lubricant should be used on plastic and rubber components. The most common types of body lubricants are listed below:

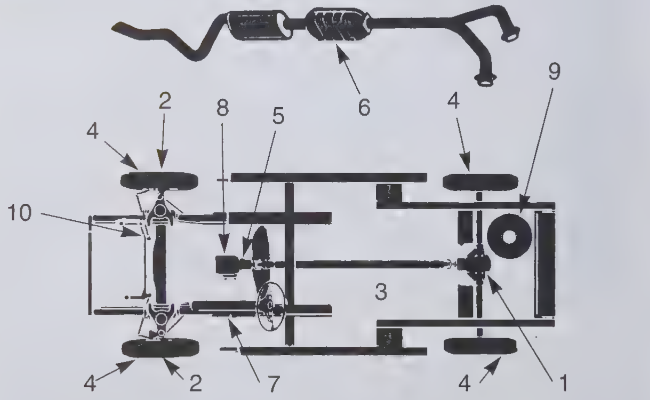
- ***Engine oil***—used on hard-to-reach high-friction points.
- ***Graphite***—excellent for door and trunk locks. It will not collect dust and dirt, which could upset lock operation.
- ***Dry stick (wax) lubricant***—desirable on door latches and strikers (post that engages the door latch). See **Figure 10-19.** It will not stain clothing.
- ***Chassis grease***—good all-around body lubricant. It can be used on easy-to-reach hinges and latches.
- ***Silicone lubricant***—often comes in a spray can. It is especially suited for rubber door weather stripping and windows. It is a dry lubricant that will not soil windows and clothing.

Service Intervals

A ***service interval*** is the amount of time (in months) or the number of miles between recommended service checks or maintenance operations. The factory service manual will give exact intervals for the particular make, model, and year of vehicle. New vehicles tend to have longer intervals before service is required.

Figure 10-20 shows the service manual recommendations for chassis maintenance on one vehicle. Note the intervals for each service operation. They are typical.

Note!
Chapter 47, *Engine Tune-Up,* gives general engine maintenance intervals. Refer to this chapter if needed.



Component	Service	Interval
1. Axle differential	✓	5000 mi (8 000 km) 30,000 mi (48 000 km)
2. Bearings, front wheel	a.	30,000 mi (48 000 km)
3. Body lubrication	b.	15,000 mi (24 000 km)
4. Brake inspection	✓ c.	15,000 mi (24 000 km)
5. Clutch lever		30,000 mi (48 000 km)
6. Exhaust system inspection	✓ d.	15,000 mi (24 000 km)
7. Manual steering gear	✓ e.	5000 mi (8 000 km)
8. Manual transmission	✓ e.	5000 mi (8 000 km)
9. Spare tire	✓ f.	7500 mi (12 000 km)
10. Steering, suspension, and chassis	✓ g. h.	15,000 mi (24 000 km) 30,000 mi (48 000 km)

Figure 10-20. Study the chassis maintenance information from a service manual. Recommendations for other parts of the car are also given in the manual. (DaimlerChrysler)

General Inspection and Problem Location

As you perform lubrication service or any kind of auto repair, always watch for mechanical problems. Visually inspect the vehicle for any signs of wear, deterioration, loose parts, or leaks. Check the condition of fan belts, water hoses, fuel hoses, vacuum hoses, and wiring. This can be done as you are working.

- ***Hose inspection*** includes checking for hardening, softening, cracking, splitting, or other signs of impending failure. See **Figure 10-21.** Squeeze all the hoses. If the hoses are deteriorating (hard or soft), inform the customer or shop supervisor of the problem.
- ***Drive belt inspection*** includes looking for splitting, tears, cuts, and wear. If worn or loose, the belt may slip and squeal. Refer to **Figure 10-22.**
- ***Wiring inspection*** involves looking for improper routing, cracked or brittle insulation, or other obvious problem signs. Make sure wires are away from all moving or hot parts.
- ***Tire inspection*** is done by looking for excessive wear, improper inflation, or physical damage. This is very important from a safety standpoint.
- ***Steering system inspection*** includes checking for excessive wear and play in moving parts. The steering wheel should *not* move more than about an inch (25 mm) without causing front wheel movement. If it does, wear in the steering mechanism is indicated.
- ***Exhaust system inspection*** involves looking for damaged, rusted, or leaking parts. The exhaust system should be inspected any time a vehicle is raised on a lift. Poisonous exhaust fumes make a leaking exhaust system very dangerous. Look for rust holes in the pipes, muffler, and other parts.

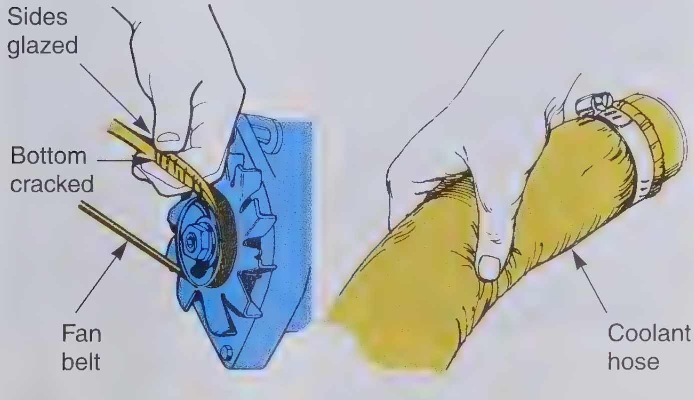


Figure 10-21. Check the condition of all hoses and belts. Inspect belts for glazing, cracking, and fraying. Feel hoses for hardening or softening. Look for leaks. (Gates Rubber Co.)

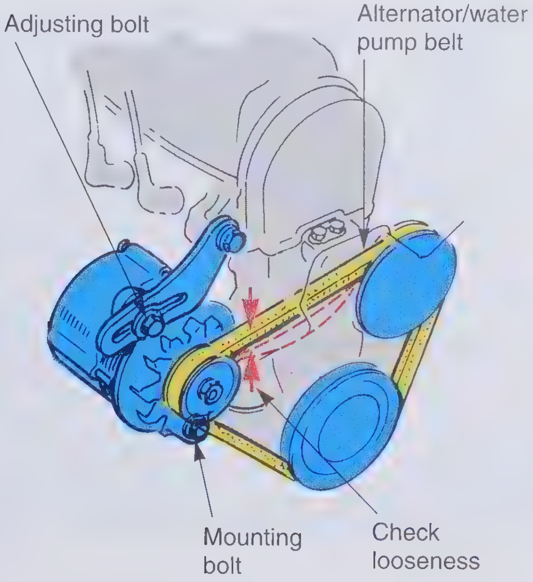

Figure 10-22. Belts should not be too loose or too tight. To adjust, loosen correct mounting bolts and the adjustment bolt. Using directions in service manual, pry the component outward and tighten the adjusting bolt. Then, tighten the mounting bolts. Recheck belt tightness. (Honda)

When working on a vehicle, be alert for these kinds of problems. This will show the shop supervisor and the customer that you are a concerned, competent technician.

Fluid Leaks

Fluid leaks result from bad gaskets, seals, or hoses; cracks in parts; and similar troubles. Leaks are very common problems that should be corrected. See **Figure 10-23.** To become good at leak detection and correction, you should:

- Become familiar with the *color*, *smell*, and *feel* (texture) of the different fluids. Then, you will be able to quickly identify a fluid leak. Does the fluid feel more like water or oil? Dab a white paper towel into a puddle of fluid to show its color more accurately. Oil will be slippery to the touch and will be dark brown or black if used for an extended period of time. If the fluid is clear or brown and feels "squeaky" when rubbed between your fingers, it is probably brake fluid or hydraulic clutch fluid. Antifreeze can be green, orange, or rust colored and will feel slick. Automatic transmission fluid can be dark brown, red, or dark green with some friction material feel (gritty). Power steering fluid can be amber, red, or clear and will feel like transmission fluid.

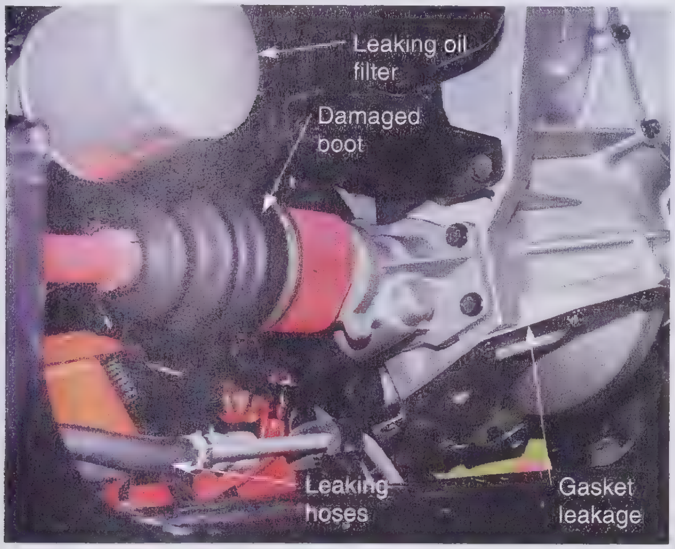

Figure 10-23. When working under a vehicle, always look for signs of fluid leakage and other obvious problems. Inspect rubber boots and hoses for signs of damage.

- Fluid leaks tend to flow downward and to the rear of the vehicle. For this reason, look for leaks above and in front of where you find fluid dripping off the vehicle.
- If multiple leaks are indicated, fix the leak located the highest and farthest forward on the vehicle. Then, repair other leaks.
- If the leaking part is badly soiled, clean the area thoroughly. Then it will be easier to see fresh fluid leaking out of the part.
- The most frequent cause of fluid leakage is broken gaskets and worn seals. Replacement will usually correct the problem. However, you should always check the parts for warpage, cracks, and dents.

Some ***stop-leak products*** are designed to recondition the leaking seal. If the seal has hardened and shrunk in size, stop-leak chemicals can fix the leak with little time and effort. If the seal is torn or the part is warped, stop-leak products will not work.

Other stop-leak products (for the cooling system, for example) contain small particles (fibrous or metallic materials) that collect at and fill the opening causing the leak. These materials can also act as a conditioner or rust preventative.

Tech Tip!
Stop-leak products will not work on hose leaks and large leaks from metal parts. These products are designed to work on small seepage problems. Refer to the manufacturer's recommendations on stop-leak products.

Noise Detection and Location

Abnormal noises are unwanted sounds that indicate part wear or other mechanical problems. They are common to almost all systems of a vehicle. When inspecting a vehicle, listen for unusual sounds (knocks, clunks, rattles, clicks, and hisses). As you work, always listen for abnormal noises.

A ***stethoscope*** (similar to that used by a doctor to listen to a patient's heart) is commonly used by an auto technician. It will help the technician pinpoint the source of internal part noises. To use the stethoscope, touch the probe on the component near the unwanted sound, **Figure 10-24.** Move the stethoscope around until the sound is the loudest.

A long screwdriver can be used in place of a stethoscope. Place the tip of the screwdriver on the part. Place the handle next to your ear. Sound will travel through the screwdriver and permit noise diagnosis. Make sure you keep the screwdriver away from moving parts or you could be injured.

A section of vacuum hose, **Figure 10-25,** is a handy device for finding sounds *not* coming from internal parts. The hose is useful for locating hissing sounds, rattles, whines, and squeaks. Place one end of the hose to your ear. Then, move the other end around the area of the sound. When the noise becomes the *loudest*, you have

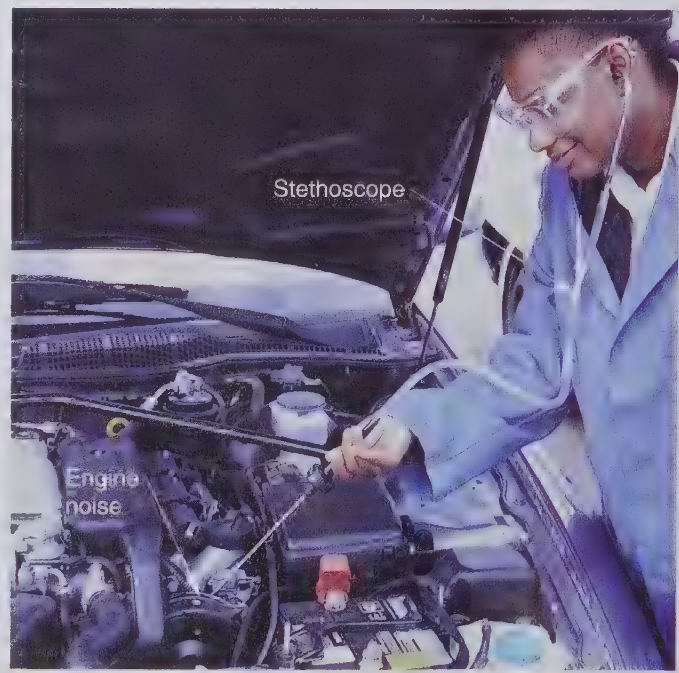

Figure 10-24. A stethoscope can be used to quickly find knocks and rattles inside components. Move the tip around on parts. When noise becomes the loudest, you have found the source of the problem.

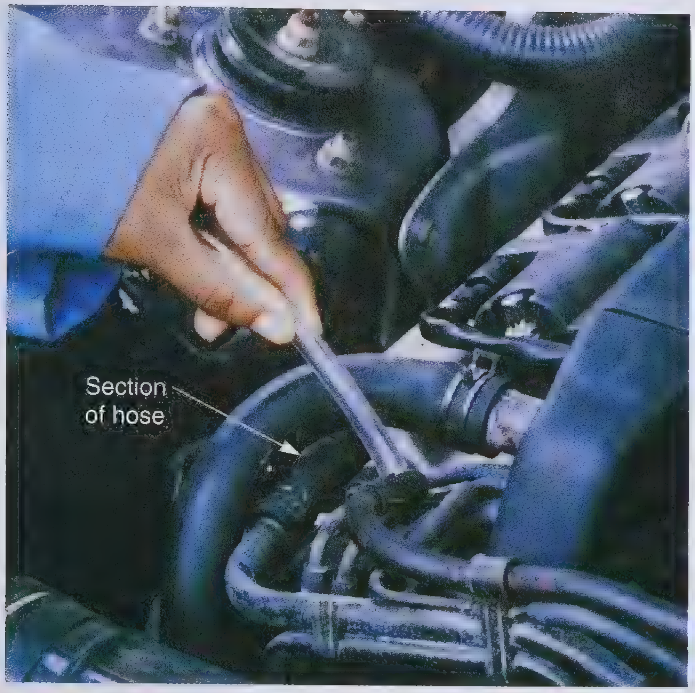

Figure 10-25. A piece of vacuum hose can be used like a stethoscope to find external noises. It will find vacuum leaks, squeaks, wind noise, and other abnormal sounds.

pinpointed the problem. Again, keep the hose away from moving or hot parts. By removing the metal end from a stethoscope, you can also listen for these kinds of noises.

Recycling and Disposal of Auto Shop Wastes

Recycling and the proper disposal of auto shop wastes are needed to help save our planet's natural resources and to reduce the amount of materials being sent to landfills. Laws have been passed that require specific procedures when handling and discarding potentially harmful materials. The following sections summarize this important information.

Auto Shop Wastes

Automotive maintenance may generate hazardous wastes that come under the requirements of the Resource Conservation and Recovery Act. This federal act covers businesses that generate, transport, and manage hazardous wastes. Any business that maintains or repairs vehicles, heavy equipment, or farm equipment is classified as a vehicle maintenance facility by this act.

Vehicle maintenance fluid and solid wastes include:

- Used motor oil (combustible and may contain toxic chemicals).
- Other discarded lubricants, such as transmission and differential fluids (like motor oil, may contain toxic chemicals).
- Used parts.
- Cleaners and degreasers that are contaminated from parts-cleaning operations.
- Carburetor and fuel injection system cleaners (contain flammable or combustible liquids).
- Rust removers (may contain strong acidic or alkaline solutions).
- Paint thinners or reducers (may be ignitable or contain toxic additives).
- Worn out batteries (lead and toxic chemicals).
- Tires and catalytic converters.

Repair and maintenance facilities (service stations, automotive dealerships, independent auto repair shops, etc.) that generate 220 lb. (100 kg) of hazardous waste monthly must file a Uniform Hazardous Waste Manifest before removing the wastes. The manifest must list the proper Department of Transportation (DOT) shipping descriptions for a number of wastes. Tables listing these descriptions are available from each state's hazardous waste management agency or a regional EPA office.

However, EPA regulations also state that no manifest is needed for used oil or lead-acid batteries if they are sent for recycling. In such cases, the material is not regarded as hazardous. Your state may have its own requirements; check with your state hazardous waste management agency.

Unless recycled for scrap metal, used oil filters are considered hazardous waste. If not recycled, they must be listed on the monthly manifest as hazardous. Before disposal, filters should be gravity drained so they do not contain free-flowing oil. Store them uncrushed in a closed, labeled container for pickup by a recycler.

Recycling Motor Oil

Used motor oil is considered hazardous waste unless it is destined to be recycled. The old oil should be stored in an approved container for recycling. One gallon of used motor oil can be refined into two and one-half quarts of high-quality motor oil. It takes about 40 gallons of crude oil to produce this much motor oil. Recycling old oil not only saves our environment from pollution, but it also helps save our natural resources. Always send used motor oil to a recycling center! Put the oil in an approved container. Some recycling companies provide a pickup service, while others require you to take the old oil to their facility.

Recycling Coolants

Antifreeze has been classified as a hazardous waste due to heavy metal and chlorinated solvents that it picks up circulating through cooling systems. It should never be mixed with used oil. The entire mixture would then be classified as a hazardous waste, even though the used oil may not be, under federal regulations.

Regulations require that spent antifreeze solutions be collected by a registered hazardous waste hauler. Several major companies offer pickup and recycling services.

Recycling Refrigerants

Refrigerants, such as R-12 and R-134a, removed from automotive air conditioning systems during servicing should not be vented to the atmosphere. State regulations require that refrigerants be recovered and recycled. See **Figure 10-26.**

As you will learn in later chapters, systems are now available for recovering, cleaning, and recycling air conditioning refrigerants.

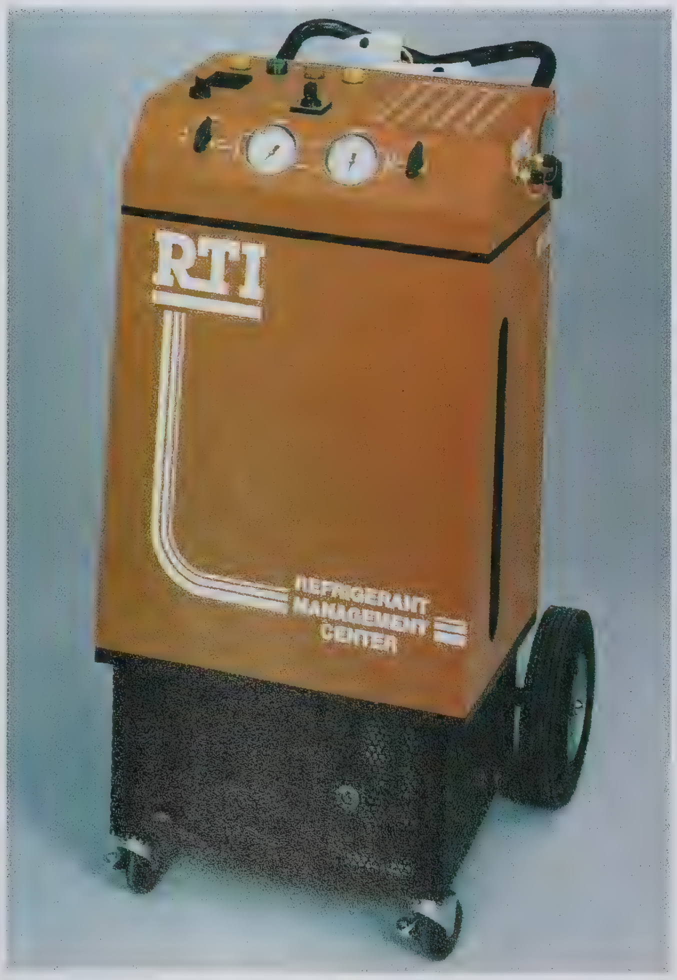

Figure 10-26. A recovery station will pull old refrigerant out of the air conditioning system. The machine will then treat used refrigerant for reuse in the vehicle. (RTI)

Other Automotive Recyclables

Other recyclable materials that are commonly removed from service during maintenance and repair of vehicles include:

- Catalytic converters, which contain platinum.
- Worn tires, which can be sold to a retreader (if the carcass is sound) or to a shredder. Shredded rubber is an ingredient in road resurfacing materials and other products that give the rubber a second use.
- Batteries can be recycled and used to make new batteries. This saves lead, acid, and other materials from adding to our waste disposal problems.
- Brake shoes can be recycled and sold as cores for making reconditioned brake shoes.
- Many small assemblies (alternators, starters, master cylinders, etc.) can be recycled and made into rebuilt parts.
- Plastic bumpers and other body parts can be recycled into a variety of new products.

Duff's Garage

Problem: Ms. Jones brought her 1996 Chevrolet Blazer in for repair because she noticed a puddle of fluid on her garage floor.

Diagnosis: Duff, the shop owner, questions Ms. Jones to find out more about what is wrong with the vehicle. He asks her about unusual sounds and odors. He also asks if she knows approximately where the fluid is leaking from (front of engine, back of engine, right side, left side, etc.). Ms. Jones says the puddle seems to be coming from the left front corner of the vehicle and that she often hears a growling noise when driving around corners. After listening carefully to Ms. Jones, Duff suspects that the power steering system might be leaking and that the growling noise may be caused by air in the power steering system. Duff then turns the repair over to the shop's suspension and steering technician. Duff discusses the symptoms with her and tells her what he thinks the problem is.

The technician checks for dripping under the engine compartment and finds a small fresh puddle that looks and smells like power steering fluid. She then opens the hood and looks for the source of the leak. As she feels around the power steering pump and hoses, she finds a leak at the hose behind the power steering pump. She then starts the engine and uses a lighted mirror to observe the fluid dripping from the crimped metal fitting on the hose.

Repair: The technician orders and installs a new power steering hose. She then fills the system with fluid, starts the engine, and rotates the steering wheel back-and-forth between the stops to purge air from the system. After test driving the vehicle, she lets it run for approximately 15 minutes and then rechecks the system for leaks. After verifying that the problem has been corrected, the technician rechecks the power steering fluid level and releases the vehicle to the customer.

Summary

- Vehicle fluids include engine oil, coolant, brake fluid, transmission fluid, power steering fluid, and other liquids.
- Vehicle maintenance includes any operation that will keep a vehicle in good operating condition.
- A car's warranty can become void if improper fluids or incorrect service procedures or intervals are used.
- Be careful! Oil and other fluids at operating temperature can be hot enough to burn.
- EPA (Environmental Protection Agency) guidelines and state regulations affect how you must handle and dispose of used fluids, solvents, and other shop chemicals.
- Never remove a radiator cap while the engine or radiator is hot. Boiling coolant can spray out of the radiator, causing serious burns.
- Hold a shop rag around fuel line fittings when loosening. This will keep fuel from spraying or leaking out, preventing a possible explosion and fire.
- During a grease job, you must lubricate high-friction pivot points on the suspension, steering, and drive train systems.
- Wheel bearings are usually packed (filled) with grease during lubrication service.
- As you perform a lubrication job or any kind of auto repair, always watch for mechanical problems. Visually inspect the vehicle for any signs of wear, deterioration, loose parts, or leaks.
- A stethoscope (similar to that used by a doctor to listen to a patient's heart) is commonly used by a technician.
- A section of vacuum hose can be used as a handy device for finding sounds not coming from inside parts.

Review Questions—Chapter 10

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What seven steps does lubrication service typically involve?
2. _____ _____ includes any operation that will keep the car in good operating condition.
3. When checking engine oil, allow the engine to cool completely. True or False?
4. What can happen when too much oil is added in an engine?
5. Which of the following should *not* be done when changing an engine's oil and filter?
   (A) Torque the drain plug only enough to prevent leaking and loosening.
   (B) Use an oil filter wrench to remove the old filter.
   (C) Wipe clean engine oil on the new filter O-ring seal.
   (D) Use a filter wrench to tighten the filter.
6. The automatic transmission dipstick is normally located in front of the engine. True or False?
7. Check automatic transmission or transaxle fluid with the engine running. Check engine oil with the engine off. True or False?
8. Explain how to check the following:
   (A) Engine coolant level and condition.
   (B) Power steering fluid.
   (C) Brake fluid.
   (D) Manual steering fluid.
   (E) Battery condition.

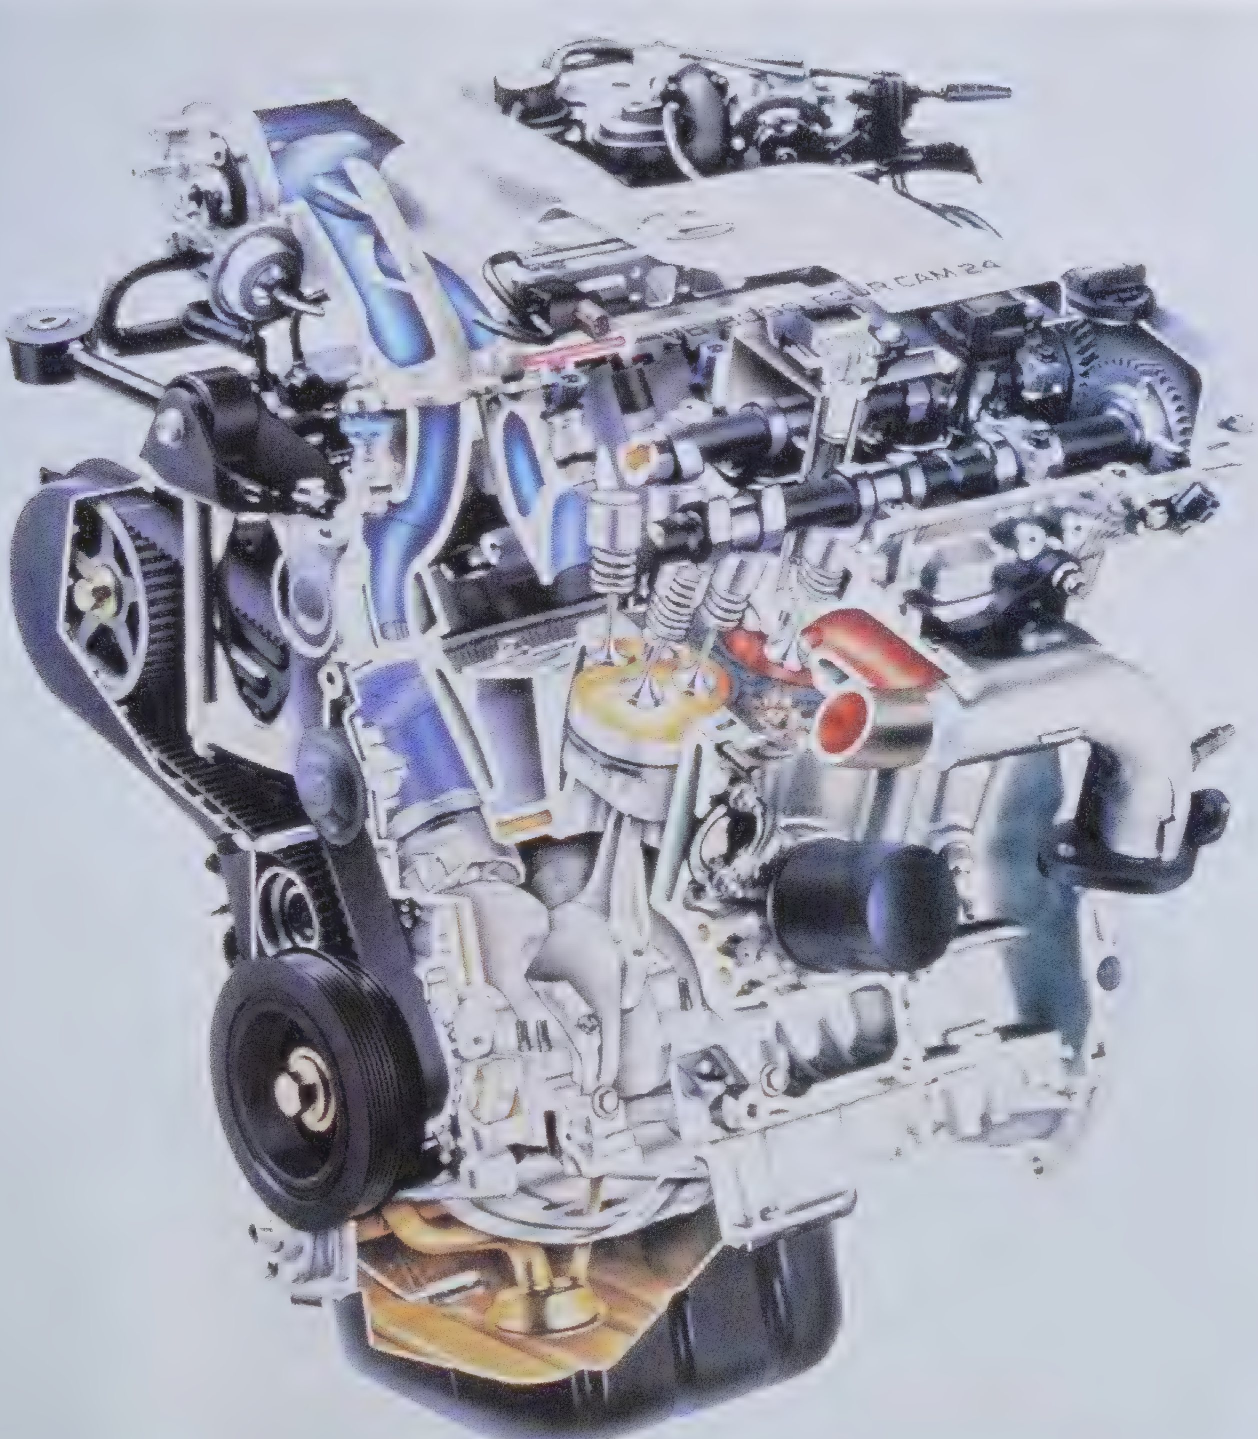
9. A(n) _____ _____ involves lubricating the steering, suspension, and drive train of a vehicle.
10. List and explain the use of five lubricants.
11. A(n) _____ _____ is the amount of time between recommended service or maintenance operations.
12. Describe six general inspection points that should be checked during vehicle maintenance.
13. Which of the following should be done to help with leak detection and troubleshooting skills?
    (A) Become familiar with the color and smell of different fluids.
    (B) Trace the problem to the highest point of wetness or leakage.
    (C) Clean the area around the leak if the leak is difficult to isolate.
    (D) All of the above.
14. A(n) _____ is commonly used to find the source of noises inside parts.
15. List four automotive items that should be recycled.

ASE-Type Questions

1. During a complete lubrication service, all of the following are done *except*:
    (A) change engine oil.
    (B) change oil filter.
    (C) check all fluid levels.
    (D) check ride height.
2. During an oil change, Technician A says to use an oil filter wrench to remove the old oil filter. Technician B says to apply a little oil to the seal on the new filter to aid installation. Who is correct?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
3. When changing engine oil, Technician A says the engine oil should be cool. Technician B says the oil should be warm. Who is correct?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
4. When checking automatic transmission fluid, the following should be done.
    (A) Engine off, transmission in park.
    (B) Engine running, transmission in park.
    (C) Engine off, transmission in neutral.
    (D) Engine on, transmission in neutral.
5. Engine coolant consists of:
    (A) water and antifreeze.
    (B) oil and antifreeze.
    (C) water and stop leak.
    (D) water only.

Activities—Chapter 10

1. On a vehicle chosen by your instructor, determine the capacity of the cooling system. Then determine the amounts of water and antifreeze needed to produce a 50/50 mixture.
2. Survey the motor oils offered for sale at a local outlet. Determine the cost to change the motor oil in a vehicle named by your instructor. Add labor cost at $36/hour.
3. Change the oil and filter on a vehicle designated by your instructor.



Cutaway of a late-model V-6 engine. With proper maintenance, this engine will provide years of trouble free operation. (Lexus)

Section 2

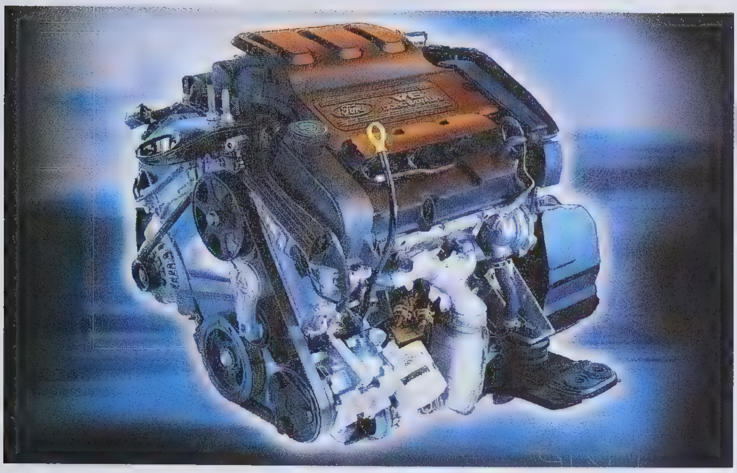
Engines

11. Engine Fundamentals
12. Engine Classifications
13. Engine Top End Construction
14. Engine Bottom End Construction
15. Engine Front End Construction
16. Engine Size and Performance Measurements

The engine is the "power plant" that produces the energy needed to propel the vehicle and operate other systems. It converts the heat energy of a fuel (gasoline, diesel oil, alcohol, etc.) into movement. If you know how an engine is constructed and how it is designed to operate, you will be better prepared to diagnose problems when it malfunctions.

Section 2 details the construction and operation of late-model automotive engines. It reviews the four-stroke cycle, explains the names and locations of major parts, describes design variations, and summarizes engine size and performance measurements.

The information presented in this section will help you pass ASE Test A1, *Engine Repair.* It will also help you prepare for later chapters on engine service and repair.



11

Engine Fundamentals

After studying this chapter, you will be able to:

- Identify the major parts of a typical automotive engine.
- Describe the four-stroke cycle.
- Define common engine terms.
- Explain the basic function of the major parts of an automotive engine.
- Cite and demonstrate safe working practices related to engines.
- Correctly answer ASE certification test questions that require knowledge of the basic operation of piston engines.

In the first chapter, you learned a little about how an engine operates. This chapter will build upon that information by explaining each engine part in more detail. What you learn here will help you prepare for other coverage of engine types, engine construction, engine diagnostics, and engine service.

Note!
If needed, quickly review the material on engines and engine systems in Chapter 1, *The Automobile.* A sound understanding of engine theory and engine support systems is very important.

Engine Operation

The ***engine*** is the source of power for the vehicle. For this reason, it is also called a power plant. An energy source, or ***fuel*** (usually gasoline or diesel oil), is burned inside the engine's ***combustion chamber*** (hollow area between the top of the piston and the bottom of the cylinder head) to produce heat. The heat causes ***expansion*** (enlargement) of the gases in the engine.

The burning and expansion of the gases in the combustion chamber produces pressure. The engine piston, connecting rod, and crankshaft convert this pressure into motion for moving the car and operating its other systems.

Figure 11-1 shows how an engine converts fuel into a useful form of energy. Combustion pressure forces the piston down. By linking the piston to the crankshaft, an engine can produce a powerful spinning motion. The rotating crankshaft can be used to drive gears, chains and sprockets; belts and sprockets; and other drive mechanisms.

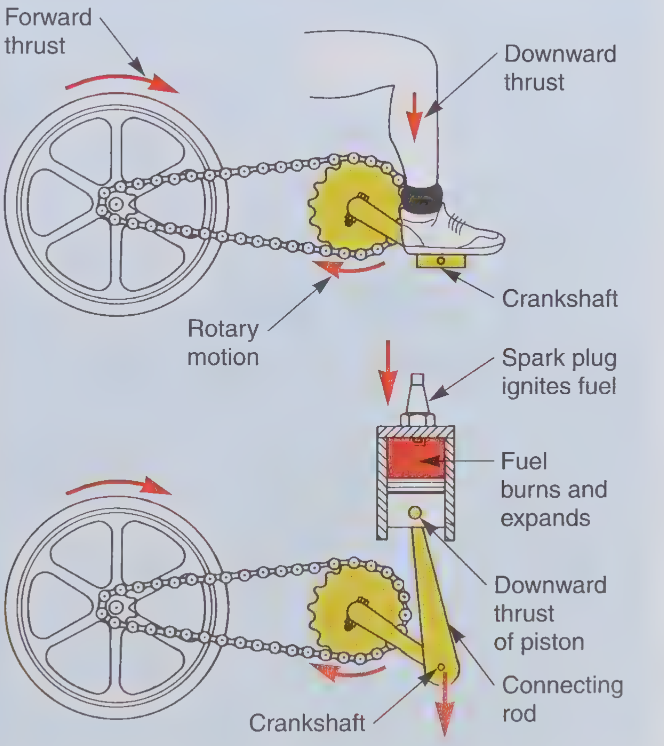


Figure 11-1. A crankshaft converts the downward thrust of the piston into useful rotating motion. The rotating motion can be used to operate the drive mechanism.

Piston Travel (TDC, BDC)

The distance the piston can travel up or down in the cylinder is limited by the crankshaft. When the piston is at the *highest point* in the cylinder, it is at ***top dead center (TDC).*** When the piston slides to its *lowest point* in the cylinder, it is at ***bottom dead center (BDC).*** See **Figure 11-2.**

Piston Stroke

Piston stroke is the distance the piston slides up or down from TDC to BDC. This takes one-half turn of the crankshaft. The crank rotates 180° during one piston stroke. Refer to **Figure 11-2.**

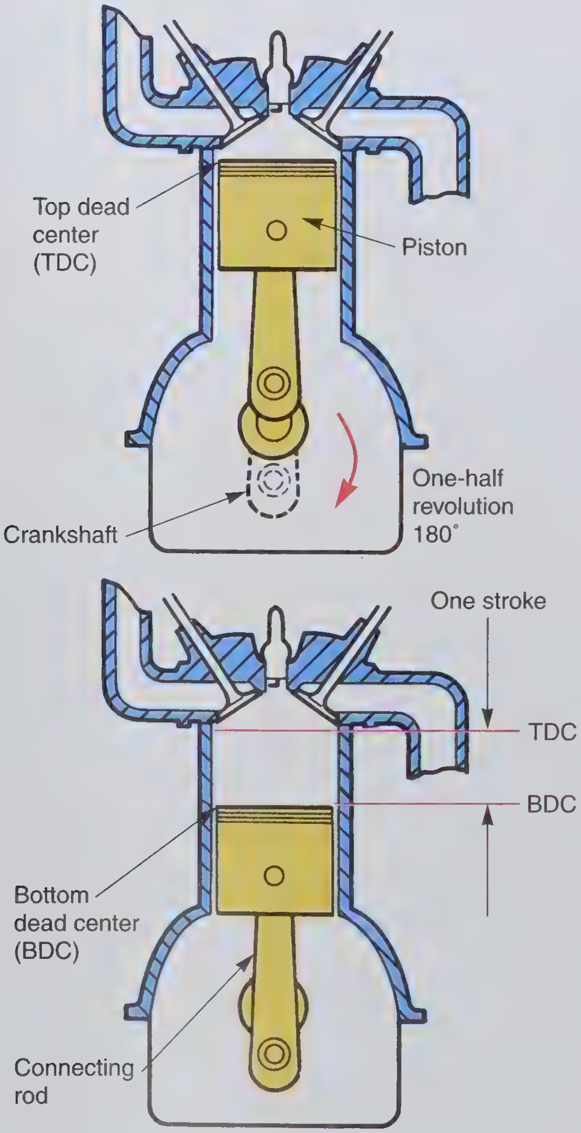

Figure 11-2. TDC means the piston is at the top of its stroke. BDC means the piston is at the bottom of its stroke. A stroke is one piston movement. (Ford)

Four-Stroke Cycle

The ***four-stroke cycle*** requires four piston strokes to complete one cycle (complete series of events). Every four strokes, the engine produces one *power stroke* (useful energy). Almost all automobiles use four-stroke-cycle engines. Look at **Figure 11-3** to review the four-stroke cycle.

The ***intake stroke*** of a gasoline engine draws fuel and air into the engine. The intake valve is open and the exhaust valve is closed. The piston slides down and forms a low-pressure area, or vacuum, in the cylinder. Outside air pressure then pushes the air-fuel mixture into the cylinder.

The ***compression stroke*** squeezes the air-fuel mixture to prepare it for combustion (burning). The mixture is more combustible when pressurized. During this stroke, the piston slides up with both valves closed.

The ***power stroke*** burns the air-fuel mixture and pushes the piston down with tremendous force. This is the only stroke that does not consume energy—it produces energy. When the spark plug fires (gasoline engine), it ignites the air-fuel mixture. Since both valves are still closed, pressure forms on the top of the piston. The piston is forced down, spinning the crankshaft.

The ***exhaust stroke*** removes the burned gases from the engine and readies the cylinder for a fresh charge of air and fuel. During this stroke, the piston moves up. The intake valve is closed and the exhaust valve is open. The burned gases are pushed out the exhaust port and into the exhaust system.

The crankshaft must rotate *two* complete revolutions to complete the four-stroke cycle. With the engine running, this series of events happens over and over very quickly.

Engine Bottom End

The term ***engine bottom end*** generally refers to the block, crankshaft, connecting rods, pistons, and related components. Another name for engine bottom end is the ***short block***. It is an assembled engine block with the cylinder heads, intake manifold, exhaust manifold, and other external parts *removed.*

Engine Block

The ***engine block,*** also called ***cylinder block,*** forms the main body of the engine. Other parts bolt to or fit inside the block. **Figure 11-4** shows a cutaway view of a basic block with parts installed.

The ***cylinders,*** also known as the ***cylinder bores,*** are large, round holes machined through the block from top to bottom. The ***pistons*** fit into the cylinders of the engine

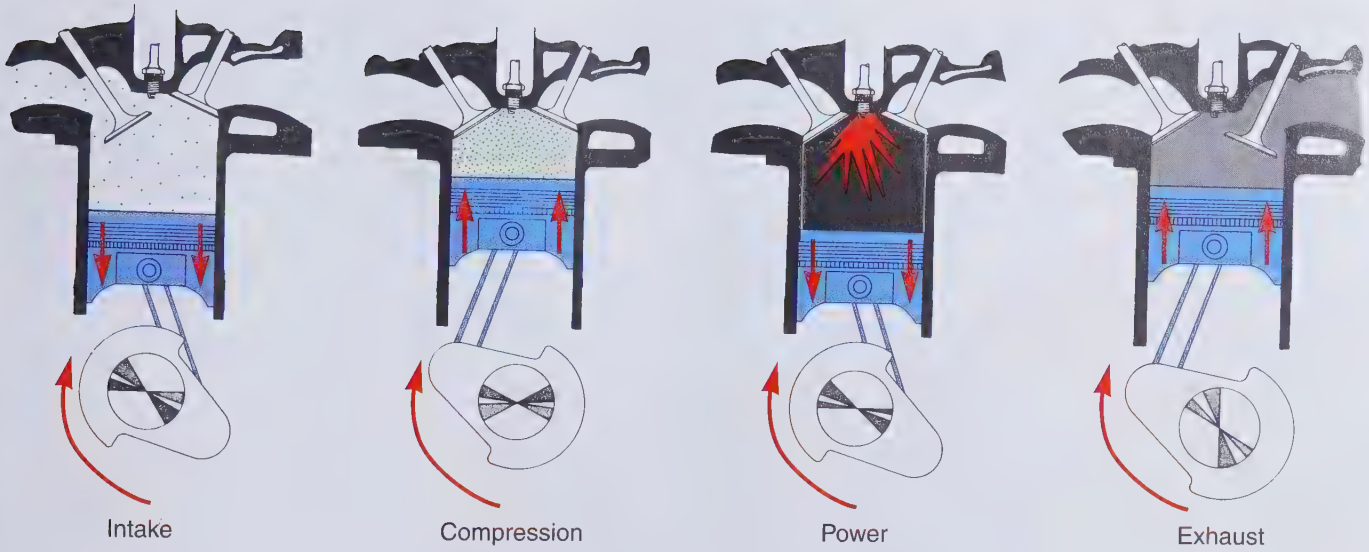

Figure 11-3. Restudy the basic four-stroke cycle. (TRW)

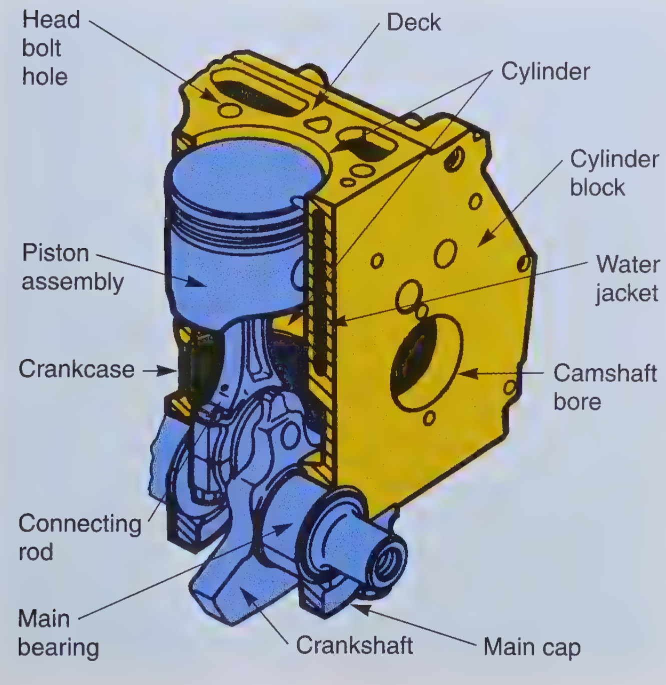

Figure 11-4. The block is the main supporting member of the engine. Note how the other parts fit into the block. (Ford)

block. The cylinders are slightly larger than the pistons. This lets the pistons slide up and down freely.

The ***deck,*** or ***deck surface,*** is the top of the block surrounding the cylinders. It is machined perfectly flat. The cylinder head bolts to the deck. Oil and coolant passages through the deck surface allow lubrication and cooling of the cylinder head parts.

Water jackets are coolant passages through the block. They allow a solution of water and antifreeze to cool the cylinders.

Core plugs, or ***freeze plugs,*** are round, metal plugs on the outside of the block. They seal holes left in the block after *casting* (manufacturing in a foundry). The plugs prevent coolant leakage out of the water jackets. Some new engines do *not* have freeze plugs.

The ***main bearing bores*** are holes machined in the bottom of the block to hold the crankshaft. Removable ***bearing inserts*** fit into these bores.

Main caps bolt to the bottom of the block and hold the crankshaft and main bearing inserts in place. Two or four large bolts normally secure each cap to the block. The caps and the block together form the main bearing bores.

The crankcase is the lowest portion of the block. The crankshaft rotates inside the crankcase.

Crankshaft

The ***crankshaft*** harnesses the tremendous force produced by the downward thrust of the pistons. It changes the up-and-down motion of the pistons into a rotating motion. The crankshaft fits into the bottom of the engine block, **Figure 11-5. Figure 11-6** pictures an engine crankshaft. Refer to this illustration as it is explained.

The ***crankshaft main journals*** are surfaces that are precisely machined and polished. They fit into the block's main bearings.

The ***crankshaft rod journals*** are also machined and polished surfaces, but they are offset from the main journals. The connecting rods bolt to the rod journals. With the engine running, the rod journals circle around the centerline of the crankshaft.

Counterweights are formed on the crankshaft to prevent vibration. These weights counteract the weight of

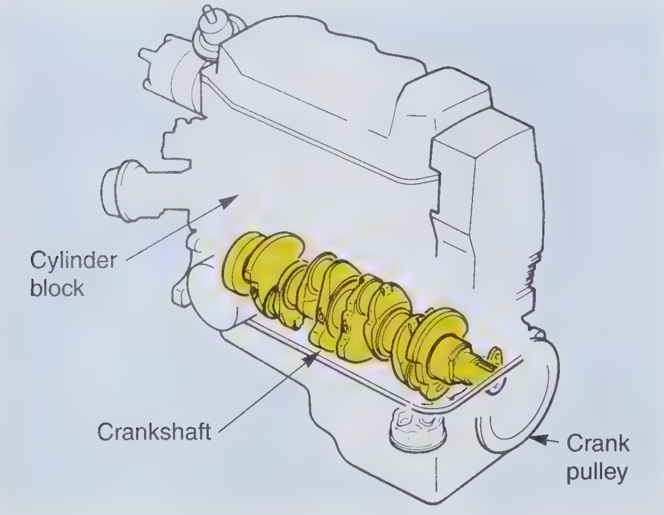

Figure 11-5. The crankshaft fits into the bottom of the block. (Ford)

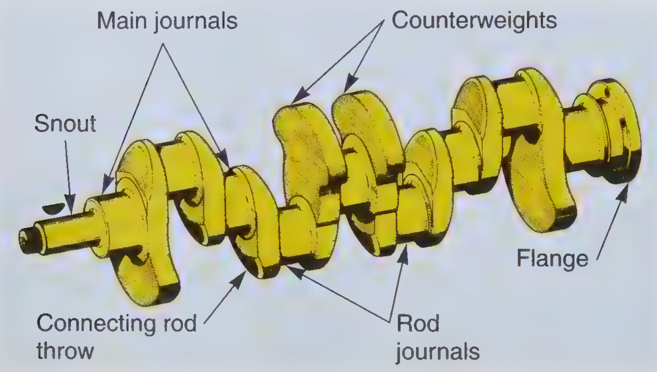

Figure 11-6. Study the basic parts of a crankshaft. Journals are very smooth surfaces for the bearings.

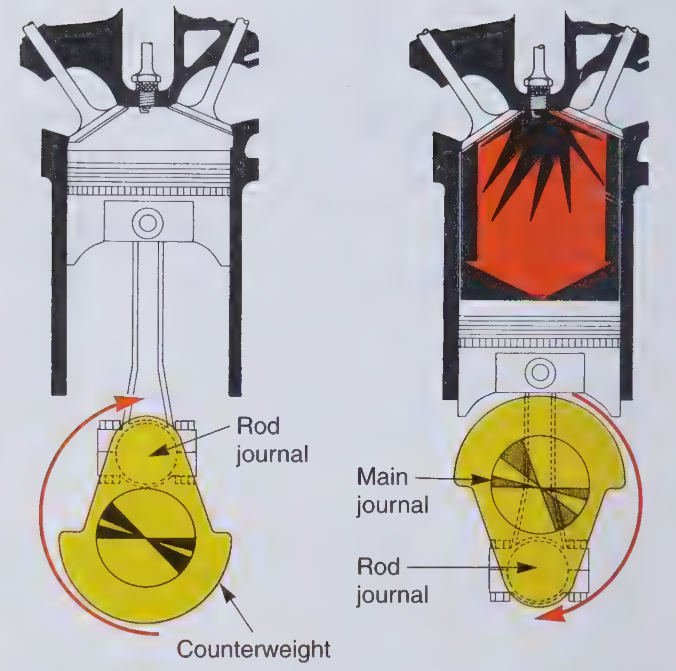

Figure 11-7. As an engine runs, the connecting rod journal spins around the main journal. The counterweight offsets the weight of the piston and rod to prevent vibration. (TRW)

the connecting rods, pistons, rings, and rod journal offset. See **Figure 11-7.**

The ***crankshaft snout*** sticks through the front of the block. It provides a mounting place for the camshaft drive mechanism, front damper, and fan belt pulleys.

A ***crankshaft flange*** holds the flywheel. The flywheel bolts to this flange. The center of the flange has a pilot hole or bushing for the transmission torque converter or input shaft.

Automobile engines normally have 4, 6, or 8 cylinders. The crankshaft rod journals are arranged so there is always at least one cylinder on a power stroke. As a result, force is always being transmitted to the crankshaft to smooth engine operation.

Engine Main Bearings

The ***engine main bearings*** are removable inserts that fit between the block main bore and the crankshaft main journals. One-half of each insert fits into the block. The other half fits into the block main caps. Refer to **Figure 11-8** and study the parts.

Oil holes in the upper bearing inserts line up with oil holes in the block. This allows oil to flow through the block and main bearings, and into the crankshaft. The oil flows through the crankshaft to lubricate the main bearings and the connecting rod bearings. This prevents metal-to-metal contact.

A ***main thrust bearing*** limits the distance the crankshaft can slide forward or rearward in the block. Flanges are formed on the main thrust bearing. These flanges almost touch the thrust surfaces on the crankshaft. This limits crankshaft end play (front-to-rear movement). See **Figure 11-9.** Normally, only one of the main bearings serves as a thrust bearing.

Main bearing clearance is the space between the crankshaft main journal and the main bearing insert. The clearance allows lubricating oil to enter and separate the journal and bearing. This allows the journal to rotate without rubbing on the bearing and causing excess wear.

Crankshaft Oil Seals

Crankshaft oil seals keep oil from leaking from the front and rear of the engine. The oil pump forces oil into the main and rod bearings. This causes oil to spray out of the bearings. Seals are placed around the front and rear of the crankshaft to contain this oil.

Main bearing

Figure 11-9. Main bearing inserts fit between the crankshaft main journals and the block. One bearing has thrust surfaces to control crankshaft end play. Oil holes and grooves allow oil to lubricate the bearings. (Federal Mogul)

The ***rear main oil seal*** fits around the rear of the crankshaft to prevent oil leakage, as pictured in **Figure 11-8.** It can be a one- or two-piece seal. The seal lip rides on a machined and polished surface on the crankshaft.

The front seal prevents oil leakage around the crankshaft snout. It is normally a one-piece seal that is pressed into the engine's front cover (metal housing that bolts to the front of the engine). The seal lip may contact the crankshaft directly, or it may contact a sleeve that fits over the crankshaft snout.

Flywheel

A ***flywheel*** is a large metal disk mounted on the rear of the crankshaft. Look at **Figure 11-8.** A flywheel can have several functions:

- The flywheel connects the engine crankshaft to the transmission or transaxle. Either the manual clutch or the automatic transmission torque converter bolts to the flywheel.

- The flywheel for a vehicle with a manual transmission is very heavy and can help smooth engine operation.
- The flywheel generally contains a large ***ring gear,*** which is used to start the engine. A small gear on the starting motor engages the flywheel ring gear and turns the flywheel.

Connecting Rod

The ***connecting rod*** fastens the piston to the crankshaft. It transfers piston movement and combustion pressure to the crankshaft rod journals. The connecting rod also causes piston movement during the non-power-producing strokes (intake, compression, and exhaust). Refer to **Figure 11-10** as the connecting rod is discussed.

The ***connecting rod small end,*** or ***top end,*** fits around the piston pin. Also called the upper end, it contains a one-piece bushing. The bushing is pressed into the rod small end.

The ***connecting rod I-beam*** is the center section of the rod. The I-beam shape provides a very high strength-to-weight ratio. It prevents the rod from bending, twisting, and breaking.

The ***connecting rod cap*** bolts to the bottom of the connecting rod body. It can be removed for disassembly of the engine.

The ***connecting rod big end,*** or ***lower end,*** is a hole machined in the rod body and cap. The connecting rod bearing fits into the big end.

Connecting rod bolts and ***nuts*** clamp the rod cap and rod together. They are special high tensile strength fasteners. Some rods use cap screws without a nut. The cap screws thread into the rod itself. This design reduces rod weight.

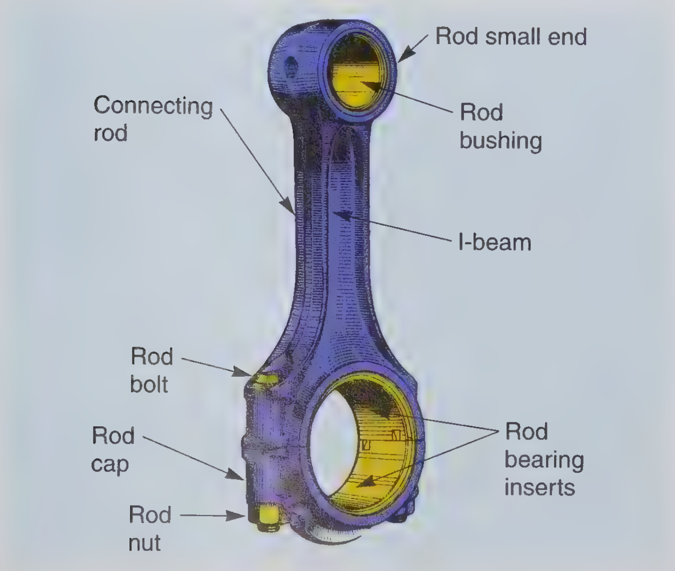

Figure 11-10. The connecting rod is the link between the piston and crankshaft.

Connecting Rod Bearings

The ***connecting rod bearings*** ride on the crankshaft rod journals. They fit between the connecting rods and the crankshaft as shown in **Figure 11-8.** The rod bearings are also removable inserts.

Rod bearing clearance is the small space between the rod bearing and crankshaft journal. As with main bearing clearance, it allows oil to enter the bearing. The oil prevents metal-to-metal contact that would wear out the crank and bearings.

Piston

The ***piston*** transfers the pressure of combustion (expanding gas) to the connecting rod and crankshaft. It must also hold the piston rings and piston pin while operating in the cylinder. **Figure 11-11** shows a cutaway view of a piston. Study this illustration as the piston is described.

The ***piston head*** is the top of the piston and is exposed to the heat and pressure of combustion. This area must be thick enough to withstand these forces. It must also be shaped to match and work with the shape of the combustion chamber for complete combustion.

Piston ring grooves are slots machined in the piston for the piston rings. The upper two grooves hold the compression rings. The lower piston groove holds the oil ring.

Piston oil holes in the bottom ring groove allow the oil to pass through the piston and onto the cylinder wall. The oil then drains back into the crankcase.

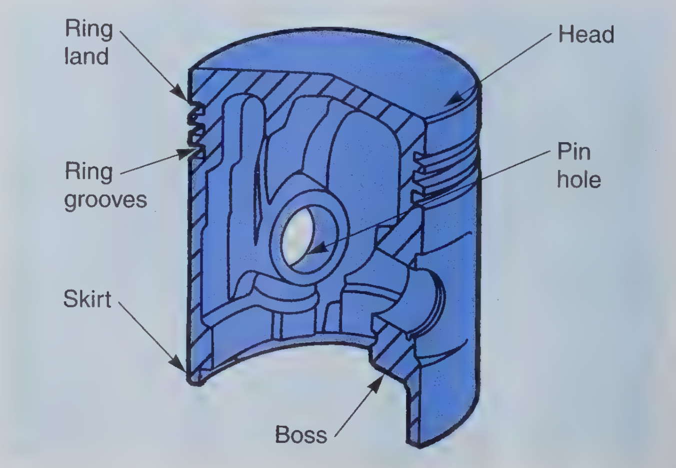

Figure 11-11. The piston rides in the cylinder and is exposed to the combustion flame. It must be light and strong. (Deere & Co.)

The ***piston ring lands*** are the areas between and above the ring grooves. They separate and support the piston rings as they slide on the cylinder.

The ***piston skirt*** is the side of the piston below the last ring. It keeps the piston from tipping in its cylinder. Without a skirt, the piston could cock and jam in the cylinder.

The ***piston boss*** is a reinforced area around the piston pin hole. It must be strong enough to support the piston pin under severe loads.

A ***piston pin hole*** is machined through the pin boss for the piston pin. It is slightly larger than the piston pin.

Piston Pin

The ***piston pin,*** also called ***wrist pin,*** allows the piston to swing on the connecting rod. The pin fits through the hole in the piston and the connecting rod small end. This is pictured in **Figure 11-12.**

Piston Clearance

Piston clearance is the amount of space between the sides of the piston and the cylinder wall. Clearance allows a lubricating film of oil to form between the piston and the cylinder. It also allows for expansion when the piston heats up. The piston must always be free to slide up and down in the cylinder block.

Piston Rings

The ***piston rings*** seal the clearance between the outside of the piston and the cylinder wall. They must keep combustion pressure from entering the crankcase. They must also keep oil from entering the combustion chambers.

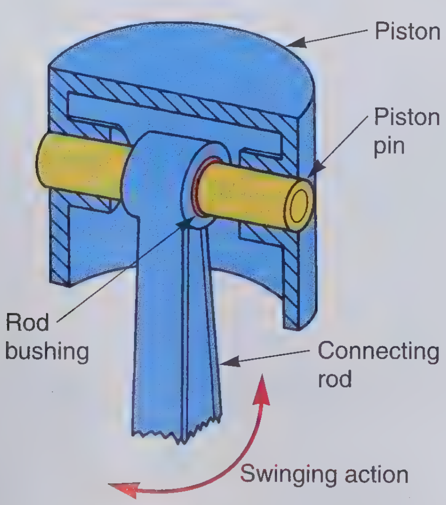

Figure 11-12. The piston pin allows the connecting rod to swing in the piston. This allows crankshaft and rod bottom end movement.

Most pistons use three rings: two upper compression rings and one lower oil ring. This is shown in **Figure 11-13.** Note ring locations.

The ***compression rings*** prevent blowby (combustion pressure leaking into engine crankcase). **Figure 11-14** shows how compression rings function in an engine.

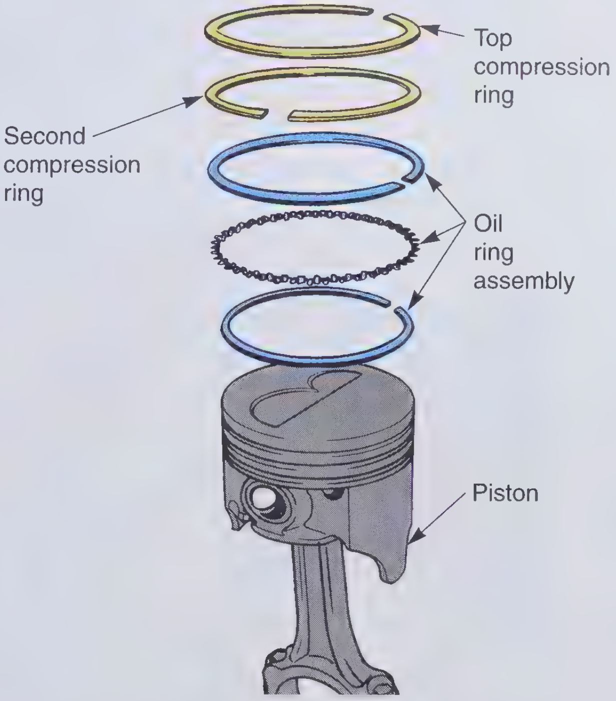

Figure 11-13. The two top piston rings are compression rings. The bottom ring is an oil ring. They fit into grooves cut in the piston. (General Motors)

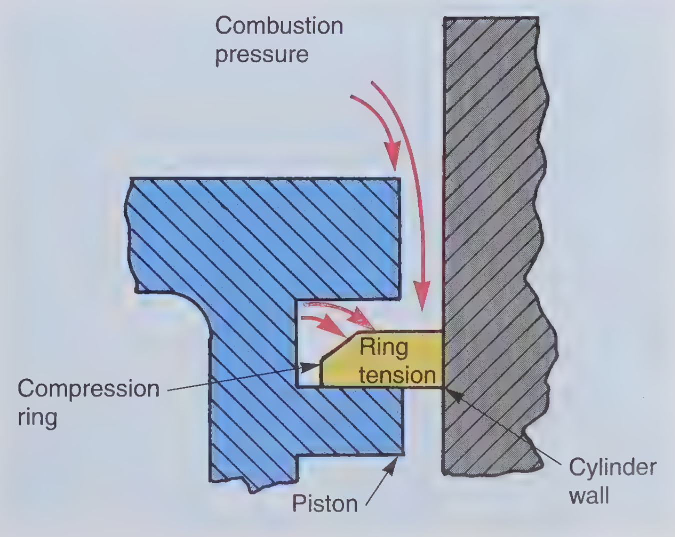

Figure 11-14. The compression ring must prevent combustion pressure from leaking between the piston and cylinder wall. Pressure actually helps push the ring against the cylinder to aid sealing.

On the compression stroke, pressure is trapped between the cylinder and piston grooves by the compression rings. Combustion pressure pushes the compression rings down in their grooves and out against the cylinder wall. This produces an almost leakproof seal.

The main job of ***oil rings*** is to prevent engine oil from entering the combustion chamber. They scrape excess oil off the cylinder wall, **Figure 11-15.** If too much oil got into the combustion chamber and was burned, blue smoke would come out of the vehicle's exhaust pipe.

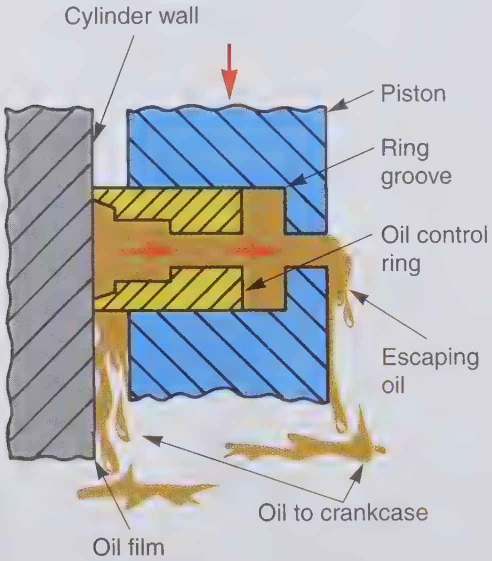

Figure 11-15. The oil control ring scrapes excess oil off the cylinder wall. If this oil entered the combustion chamber, the engine would emit blue smoke.

Ring gap is the split, or space, between the ends of a piston ring. The ring gap allows the ring to be spread open and installed on the piston. It also allows the ring to be made slightly larger in diameter than the cylinder. When squeezed together and installed in the cylinder, the ring spreads outward and presses on the cylinder wall. This aids ring sealing.

Engine Top End

The term ***engine top end*** generally refers to the cylinder heads, valves, camshaft, and other related components. These parts work together to control the flow of air and fuel into the engine cylinders. They also control the flow of exhaust out of the engine. **Figure 11-16** shows the fuel charge entering engine.

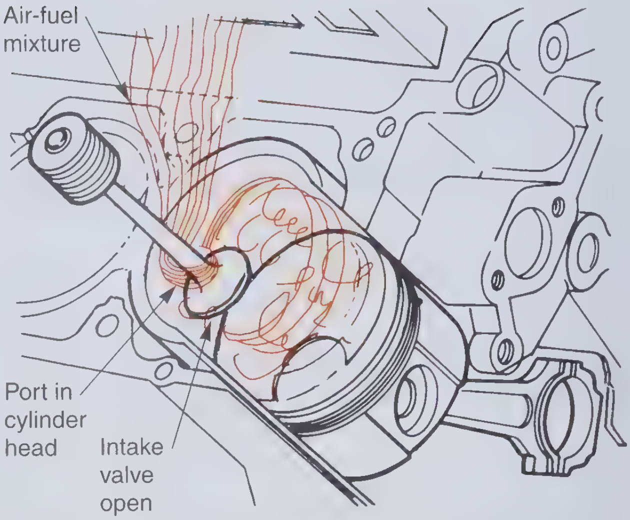

Figure 11-16. The engine top end controls the flow of the air-fuel mixture into the cylinder. It also controls the flow of exhaust out of the cylinder. (Ford)

Cylinder Head

The ***cylinder head*** bolts to the deck of the cylinder block. It covers and encloses the top of the cylinders. Refer to **Figure 11-17.**

Combustion chambers are small pockets formed in the cylinder heads. The combustion chambers are located directly over the cylinders. Combustion occurs in these areas of the cylinder head. Spark plugs (gasoline engine) or injectors (diesel engine) protrude through holes and into the combustion chambers. **Figure 11-18** shows a combustion chamber.

Intake and exhaust ports are cast into the cylinder head. The ***intake ports*** route air (diesel engine) or air and fuel (gasoline engine) into the combustion chambers. The ***exhaust port*** routes burned gases out of the engine.

Valve guides are small holes machined through the cylinder head for the valves. The valves fit into and slide in these guides.

Valve seats are round, machined surfaces in the combustion chamber port openings, **Figure 11-19.** When a valve is closed, it seals against the valve seat.

Valve Train

The ***engine valve train*** consists of the valves and the parts that operate them, **Figure 11-20.** These include the camshaft, lifters, push rods, rocker arms, valves, and valve spring assemblies. The valve train must open and close the valves at the correct time. **Figure 11-21** illustrates basic valve train action.

Valves

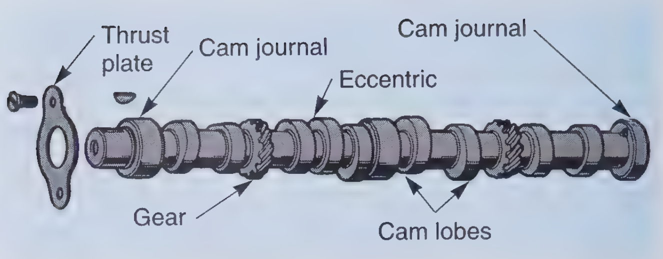
Figure 11-20. The valve train operates engine valves. Study the parts.

The specific parts of a valve train vary with engine design. This is discussed in later chapters.

Camshaft

The ***camshaft*** has lobes that open each valve. It can be located in the engine block or in the cylinder head. **Figure 11-22** illustrates a camshaft. Study this illustration as the camshaft is explained.



Thrust plate
Cam journal
Cam journal
Eccentric
Gear
Cam lobes

Figure 11-22. The camshaft is a long metal shaft with lobes, journals, and sometimes, an eccentric and gears.

The ***cam lobes*** are egg-shaped protrusions (bumps) machined on the camshaft. One cam lobe is provided for each engine valve. Assuming the engine has two valves per cylinder, a 4-cylinder engine camshaft would have eight cam lobes; a 6-cylinder, twelve lobes; etc.

The camshaft sometimes has a drive gear for operating the distributor and oil pump. A gear on the ignition system distributor may mesh with this gear.

An ***eccentric*** (oval) may be machined on the camshaft to operate a mechanical (engine-driven) fuel pump. This feature can be found on camshafts used in older engines or some diesel engines. It is similar to a cam lobe but is more round.

Camshaft journals are precisely machined and polished surfaces for the cam bearings. Like the crankshaft, the camshaft rotates on its journals. Oil separates the cam bearings and cam journals.

Lifter (tappet)
Lobe away from lifter
Valve closed

Figure 11-21. When the camshaft lobe turns into the lifter, the valve is pushed open. When the lobe rotates away from the lifter, the valve spring pushes the valve closed. (Ford)

Valve Lifters

A ***valve lifter,*** also called a ***tappet,*** usually rides on the cam lobes and transfers motion to the rest of the valve train. Refer back to **Figure 11-20.** The lifters can be located in the engine block or cylinder head. They fit into lifter bores, which are machined holes in the block or head.

When the cam lobe moves toward the lifter, the lifter is pushed up in its bore. This opens the valve. Then, when the lobe rotates away from the lifter, the lifter is pushed down in its bore by the valve spring. This keeps the lifter in constant contact with the camshaft.

Push Rods

Push rods transfer motion between the lifters and the rocker arms, **Figure 11-21.** They are needed when the camshaft is located in the cylinder block. They are *not* needed when the camshaft is in the cylinder head.

A push rod is a hollow metal tube with a ball or socket formed on each end. One end of the push rod fits into the lifter. The other end fits against the rocker arm. In this way, when the lifter slides up, the push rod moves the rocker arm.

Rocker Arms

Rocker arms can be used to transfer motion to the valves. They mount on top of the cylinder head. A pivot mechanism allows the rockers to rock back and forth, opening and closing the valves. See **Figure 11-21.**

Valves

Engine ***valves*** open and close the ports in the cylinder head. Until recently, only two valves were used per cylinder: one intake valve and one exhaust valve. To improve efficiency, many late-model engines are equipped with four valves per cylinder: two intake valves and two exhaust valves.

The ***intake valve*** is larger than the exhaust valve. It controls the flow of the fuel mixture (gasoline engine) or air (diesel) into the combustion chamber. The intake valve fits into the port leading from the intake manifold.

The ***exhaust valve*** controls the flow of exhaust gases out of the cylinder. It is smaller than the intake valve. The exhaust valve fits into the port leading to the exhaust manifold.

Valve Parts

Look at **Figure 11-23** as the basic parts of a valve are introduced.

The ***valve head*** is the large, disc-shaped surface exposed to the combustion chamber. Its outside diameter determines the size of the valve.

The ***valve face*** is a machined surface on the back of the valve head. It touches and seals against the seat in the cylinder head.

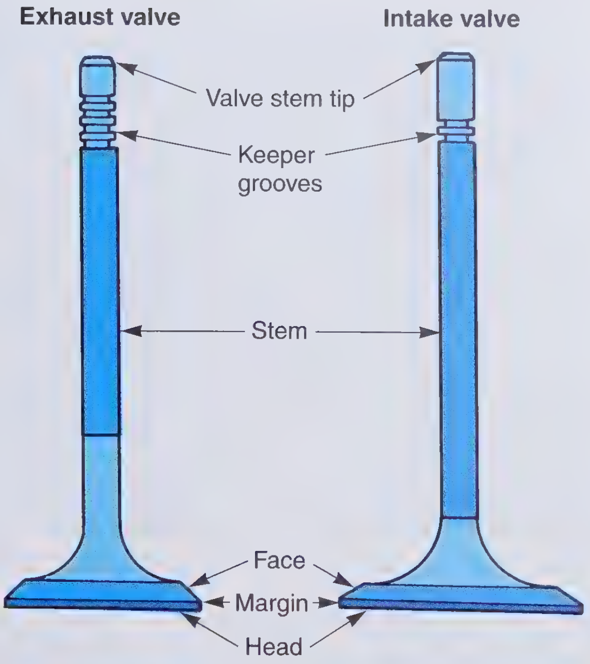

Figure 11-23. The intake valve is larger than the exhaust valve. Note the parts of each valve.

The ***valve margin*** is the flat surface on the outer edge of the valve head. It is located between the valve head and face. The margin is needed to allow the valve to withstand the high temperatures of combustion. Without a margin, the valve head would melt and burn.

The ***valve stem*** is a long shaft extending out of the valve head. The stem is machined and polished. It fits into the guide machined through the cylinder head.

Keeper grooves, or ***lock grooves,*** are machined into the top of the valve stem. They accept small keepers or locks that hold the retainer and spring on the valve.

Valve Seals

Valve seals prevent oil from entering the combustion chambers through the valve guides. This is illustrated in **Figure 11-24.**

The valve seals fit over the valve stems and keep oil from entering through the clearance between the stems and guides.

Without valve seals, oil could be drawn into the engine cylinders and burned during combustion. Oil consumption and engine smoking could result.

Valve Spring Assembly

The ***valve spring assembly*** is used to close the valve. It basically consists of a valve spring, a retainer, and two keepers. The ***keepers*** fit into the grooves cut in the valve stem. This locks the retainer and spring on the valve. See **Figure 11-25.**

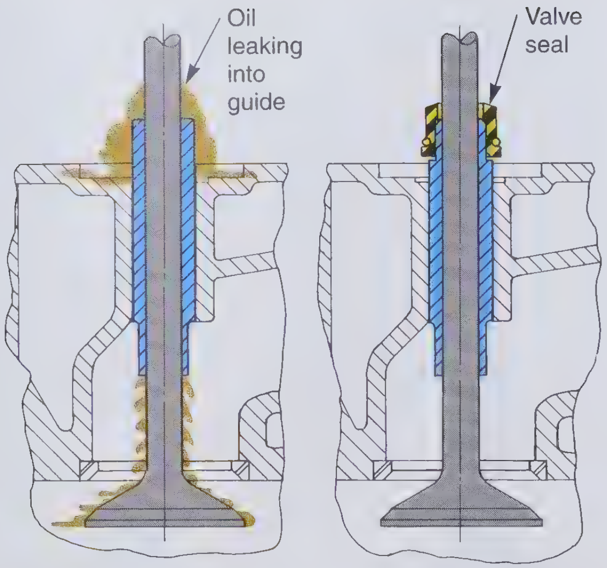

Figure 11-24. A valve seal keeps oil from entering the guide and combustion chamber. (American Hammered Piston Rings)

Intake Manifold

The ***intake manifold*** bolts to the side of the cylinder head or heads. On late-model engines, the fuel injectors and the throttle body mount on the intake manifold. On older engines, the carburetor is mounted on the top of the manifold. The intake manifold contains runners (passages) going to each cylinder head port. Air and fuel (gasoline engine) are routed through these runners, **Figure 11-26.**

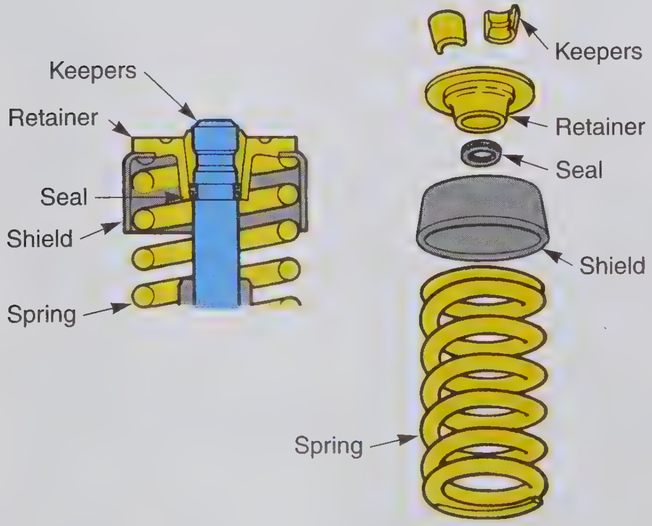

Figure 11-25. The valve spring assembly basically consists of a spring, retainer, keepers, and sometimes, a shield. Note how this type of seal fits on the valve stem. (Buick)

Exhaust Manifold

The ***exhaust manifold*** also bolts to the cylinder head; however, it fastens over the exhaust ports to carry burned gases into the exhaust system, **Figure 11-26.** During the exhaust strokes, hot gases blow into this manifold before entering the rest of the exhaust system. An exhaust manifold can be made of heavy cast iron or lightweight aluminum or stainless steel tubing. The trend is toward lighter designs.

Valve Cover

The ***valve cover,*** also called the ***rocker cover,*** is a thin metal or plastic cover over the top of the cylinder head. It simply keeps valve train oil spray from leaking out of the engine. Look at **Figure 11-26.**

Engine Front End

The ***engine front end*** operates the engine camshaft and sometimes the oil pump, distributor, engine sensors, and diesel injection pump. Basically, the engine front end consists of a drive mechanism for the camshaft and other devices, a front cover, an oil seal, and a crankshaft damper.

Tech Tip!
Engine front end assemblies are much more complicated than in the past. With today's dual overhead cam engines, the cam drive mechanism can be difficult to comprehend. Carefully study all the illustrations in this book to compare front end design differences. This will prepare you to work on various engines.

Camshaft Drive

A ***camshaft drive*** is needed to turn the camshaft at one-half engine speed. A belt and sprockets, gears, or a chain and sprockets can be used to turn the camshaft. Look at **Figure 11-27.**

These parts are often called the timing belt, timing gears, or timing chain because they time the camshaft with the crankshaft. See **Figures 11-28, 11-29,** and **11-30.**

The camshaft is designed to turn at one-half engine speed. As a result, each valve will open only once for every two crankshaft revolutions.

For instance, the intake valve must open only on the intake stroke, not the compression, power, or exhaust strokes. To do this, the camshaft gear or sprocket is twice as big as the gear or sprocket on the crankshaft.

Belt drive
Gear drive
Chain drive

Figure 11-27. The camshaft can be turned by one of three drive mechanisms: a belt drive, a gear drive, or a chain drive.

Front Cover

The ***front cover*** bolts over the crankshaft snout. It holds an oil seal that seals the front of the crankshaft.

When the engine uses a gear- or chain-type camshaft drive, the front cover can also be called the timing cover, **Figure 11-28.** With a belt drive, this cover does not enclose the cam drive or timing mechanism. A second cover is installed over the belt, **Figure 11-29.**

Crank Damper

A ***crank damper*** is a heavy wheel on the crankshaft snout. It is mounted in rubber and helps prevent crankshaft vibration and damage. This damper is also called the harmonic balancer or vibration damper.

Workplace Skills

Teamwork is the key to success in the automotive shop. Smart technicians "talk shop," exchanging information about new tools and repair methods. They also help each other with diagnosis and heavy work.

Working as part of a team will increase your job satisfaction and productivity. You will spend a large portion of your life working. Why not enjoy it?

Summary

- The engine is the source of power for the vehicle. For this reason, it is also called a power plant.
- When the piston is at its *highest point* in the cylinder, it is at TDC (top dead center). When the piston slides to its *lowest point* in the cylinder, it is at BDC (bottom dead center).
- The term engine bottom end generally refers to the block, crankshaft, connecting rods, pistons, and related components.
- The crankshaft harnesses the tremendous force produced by the downward thrust of the pistons.
- The engine main bearings are removable inserts that fit between the block main bore and crankshaft main journals.
- Main bearing clearance is the space between the crankshaft main journal and the main bearing insert.
- Crankshaft oil seals keep oil from leaking out the front and rear of the engine.
- The connecting rod fastens the piston to the crankshaft. It transfers piston movement and combustion pressure to the crankshaft rod journals.
- The engine piston transfers the pressure of combustion (expanding gas) to the connecting rod and crankshaft.
- Piston clearance is the amount of space between the sides of the piston and the cylinder wall.
- The piston rings seal the clearance between the outside of the piston and the cylinder wall.
- The compression rings prevent blowby (combustion pressure leaking into engine crankcase).
- The main job of oil rings is to prevent engine oil from entering the combustion chamber.
- The term engine top end generally refers to the cylinder heads, valves, camshaft, and related components.
- The camshaft has lobes that open the valves.
- A valve lifter usually rides on the cam lobes and transfers motion to the rest of the valve train.
- Engine valves open and close the ports in the cylinder head.
- The valve spring assembly is used to close the valve.
- The engine front end operates the engine camshaft and, sometimes, the oil pump, distributor, engine sensors, and diesel injection pump.
- A crank damper is a heavy wheel on the crankshaft snout. It is mounted in rubber and helps prevent crankshaft vibration and damage.

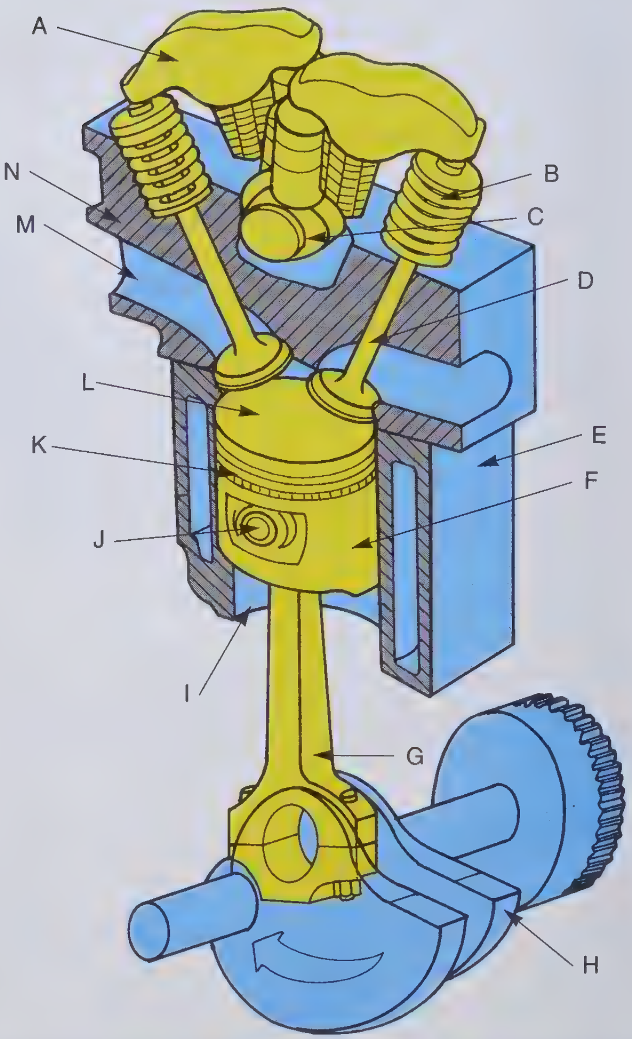
Review Questions—Chapter 11

Please do not write in this text. Place your answers on a separate sheet of paper.

1. Usually, _____ or _____ _____ is burned inside the engine to produce heat, expansion, and resulting pressure.
2. What do TDC and BDC mean?
3. Every four strokes, the engine produces two power or energy-producing strokes. True or False?

4. Explain the intake stroke.
5. Explain the compression stroke.
6. Explain the power stroke.
7. Explain the exhaust stroke.
8. _____ _____ bolt to the bottom of the block and hold the crankshaft in place.
9. The crankcase is the highest portion in the block. True or False?
10. The crankshaft changes the up-and-down motion of the piston into a useful _____ motion.
11. What is the function of crankshaft counterweights?
12. Describe the function of the main thrust bearing.
13. The _____ _____ transfers piston movement to the crankshaft.
14. The distance from the centerline of the crankshaft to the centerline of a rod journal is 3″ (76 mm). What is the total vertical distance that the piston will travel in the cylinder (from TDC to BDC)?
15. Which of the following is *not* part of a connecting rod?
    (A) I-beam.
    (B) Lobe.
    (C) Cap.
    (D) Bushing.
16. Why is rod bearing clearance needed?
17. Explain the function of compression and oil rings.
18. Which of the following is part of the cylinder head?
    (A) Combustion chambers.
    (B) Intake and exhaust ports.
    (C) Valve guides.
    (D) All of the above.
19. List and explain the basic parts of a camshaft.
20. _____ open and close the ports in the cylinder head.
21. The intake valves are larger than the exhaust valves. True or False?
22. Describe the five basic parts of an engine valve.
23. What do valve seals do and what would happen without valve seals?
24. Explain the function of the following parts.
    (A) Intake manifold.
    (B) Exhaust manifold.
    (C) Valve cover.
25. Identify the engine parts in the illustration below. Write A through N on your paper. Then write the name of the part next to each letter.



ASE-Type Questions

1. Technician A says the engine camshaft converts reciprocating motion of the piston into rotary motion for power output. Technician B disagrees and says the crankshaft performs this function. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
2. The distance a piston travels up or down in a cylinder is limited by the:
    (A) flywheel.
    (B) camshaft.
    (C) crankshaft.
    (D) valve train.

3. The air-fuel mixture is actually burned during the:
   - (A) *power stroke.*
   - (B) *intake stroke.*
   - (C) *exhaust stroke.*
   - (D) *compression stroke.*
4. How many crankshaft rotations are needed to complete the four-stroke cycle?
   - (A) *One.*
   - (B) *Two.*
   - (C) *Three.*
   - (D) *Four.*
5. Automobile engines normally have:
   - (A) *four cylinders.*
   - (B) *six cylinders.*
   - (C) *eight cylinders.*
   - (D) *All of the above.*
6. A flywheel performs each of these functions *except:*
   - (A) *contains a gear used for engine starting.*
   - (B) *smoothes engine operation.*
   - (C) *provides lubrication to parts.*
   - (D) *connects crankshaft to transmission.*
7. Which of the following causes piston movement during non-power-producing strokes?
   - (A) *Flywheel.*
   - (B) *Connecting rod.*
   - (C) *Counterweights.*
   - (D) *Main thrust bearing.*
8. Which of the following components transfers combustion pressure to the crankshaft and connecting rods?
   - (A) *Piston.*
   - (B) *Camshaft.*
   - (C) *Valve train.*
   - (D) *Thrust bearing.*
9. Which of the following keeps a piston from tipping in its cylinder?
   - (A) *Piston pin.*
   - (B) *Piston boss.*
   - (C) *Piston skirt.*
   - (D) *Piston head.*
10. An engine comes into the shop with blowby. Technician A says the engine could have a cracked flywheel. Technician B says the rings could be worn. Who is right?
    - (A) *A only.*
    - (B) *B only.*
    - (C) *Both A and B.*
    - (D) *Neither A nor B.*
11. Which of the following is *not* a valve train component?
    - (A) *Camshaft.*
    - (B) *Crankshaft.*
    - (C) *Rocker arms.*
    - (D) *Valve springs.*
12. While discussing camshaft operation, Technician A states that cam lobes open each valve in the engine. Technician B states that the camshaft journals operate engine valves. Who is right?
    - (A) *A only.*
    - (B) *B only.*
    - (C) *Both A and B.*
    - (D) *Neither A nor B.*
13. The valve train parts that transfer motion to the rest of the valve train are the:
    - (A) *lifters.*
    - (B) *tappets.*
    - (C) *Both A and B.*
    - (D) *Neither A nor B.*
14. Which of the following is used to turn the camshaft at one-half engine speed?
    - (A) *Timing belt.*
    - (B) *Timing chain.*
    - (C) *Timing gears.*
    - (D) *All of the above.*
15. Which of the following helps prevent crankshaft vibration and damage?
    - (A) *Crank damper.*
    - (B) *Vibration damper.*
    - (C) *Harmonic balancer.*
    - (D) *All of the above.*

Activities—Chapter 11

1. A camshaft changes rotary motion to up-and-down motion. Find and describe or sketch at least three other examples of ways that a mechanical system changes the type, direction, or force of a motion.
2. If possible, obtain from a repair shop a bearing or other engine part that shows severe wear. Clean the part so the wear can be seen easily and pass it around to your classmates. Discuss how the wear was caused.
3. Make a chart showing the position (open or closed) of the intake valve and the exhaust valve during each stroke of the four-stroke cycle.

12

Engine Design Classifications

After studying this chapter, you will be able to:

- Describe basic automotive engine classifications.
- Compare gasoline and diesel engines.
- Contrast combustion chamber designs.
- Discuss alternative engine types.
- Compare two- and four-stroke cycle engines.
- Correctly answer ASE certification test questions that require a knowledge of engine classifications and design differences.

In previous chapters, you learned about the basic parts of an engine. Now you are ready to learn about the various engine types, designs, and classifications used in automobiles and light trucks.

An experienced engine technician can glance into an engine compartment and "rattle off" dozens of engine facts. For example, you might hear a technician say, "This is an inline, 4-cylinder, 16-valve, overhead-cam engine." You must understand these kinds of terms when troubleshooting and repairing vehicle engines. Study this chapter carefully. It will help you learn the "language" of an automotive technician.

Engine Classifications

Even though basic engine parts are the same, design differences can change the way engines operate and how they are repaired. For this reason, you must be able to classify engines.

Some common engine classifications include:

- Cylinder arrangement.
- Number of cylinders.
- Cooling system type.
- Valve location.
- Camshaft location.
- Combustion chamber design.
- Type of fuel burned.
- Type of ignition.
- Number of strokes per cycle.
- Number of valves per cylinder.
- Type of aspiration.

Cylinder Arrangement

Cylinder arrangement refers to the position of the cylinders in relation to the crankshaft. There are five basic cylinder arrangements: inline, V-type, slant, W-type, and opposed. These are shown in **Figure 12-1.**

In an ***inline engine,*** the cylinders are lined up in a single row. Each cylinder is located in a straight line that is parallel to the crankshaft. Four-, five-, and six-cylinder engines are commonly inline engines.

Viewed from either end, a ***V-type engine*** looks like the letter "V." The two banks of cylinders lie at an angle to each other. This arrangement reduces the length and the height of the engine.

A ***slant engine*** has only one bank of cylinders. This bank leans to one side. As with V-type engines, this saves space. It allows the body and hood of the vehicle to be much lower. A relatively large engine can fit into a small engine compartment.

Like a V-type engine, the **W-type engine** consists of two cylinder banks that form a "V." However, the cylinders in each bank of the W-type engine are offset, forming a second, very narrow "V" (V+V=W). This compact design allows manufacturers to increase engine displacement without increasing engine size.

Cylinders of an ***opposed engine*** lie flat on either side of the crankshaft. Because of its appearance, this type of engine is sometimes called a "pancake engine" or "boxer engine." An opposed engine may be found in older Volkswagens and a few late-model foreign sports cars (Porsche and Subaru, for example).

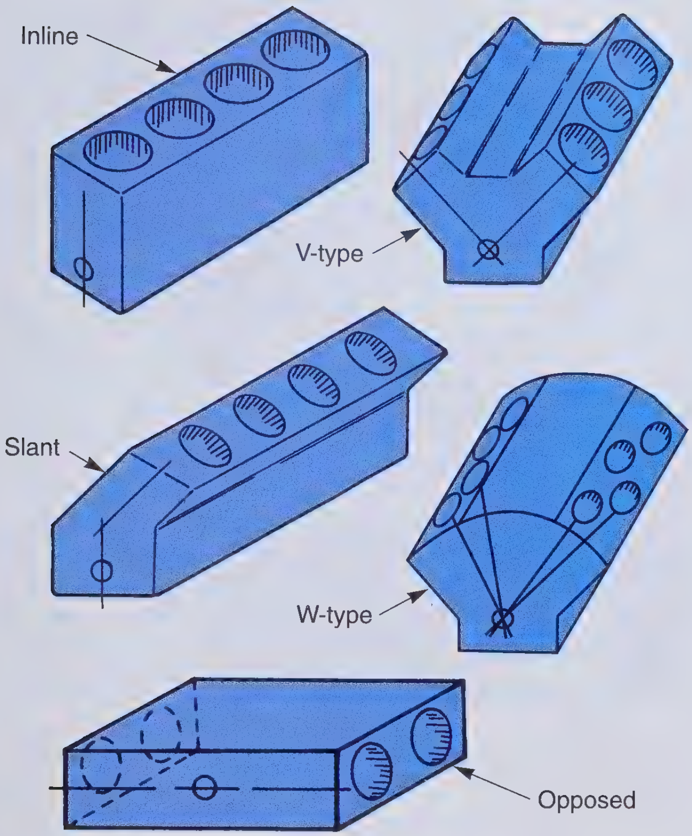


Figure 12-1. Engines can be classified by the way the cylinders are arranged in the block. The five basic cylinder arrangements used in automobiles are shown.

One advantage of an "opposed engine" is that it minimizes frictional horsepower loss at the main bearings. Inline and V-type engines produce a downward thrust on the crankshaft that causes a small but unwanted power loss. In an opposed engine, the pistons move right and left against each other to prevent a downward thrust on the main bearings. This type of engine also has a much lower center of gravity than other car and truck engines. This can be an advantage with a sports car or racing car, where a low center of gravity increases cornering ability.

Number of Cylinders

Normally, car and truck engines have either 4, 6, or 8 cylinders. A few automotive engines have 3, 5, 10, 12, or 16 cylinders.

A greater number of cylinders generally increases engine smoothness and power. For instance, an 8-cylinder engine produces twice as many power strokes per crank revolution as a 4-cylinder engine. This reduces power pulsations and roughness (vibrations) at idle. Four-cylinder engines usually have inline, slant, or opposed cylinder arrangements. Six-cylinder engines can have inline, slant, or V-type arrangements. Five-cylinder engines are normally inline engines. Eight-, 10-, and 12-cylinder engines are commonly V-type engines.

Cylinder Numbering and Firing Order

Engine manufacturers number each engine cylinder to help technicians make repairs. The service manual will provide an illustration showing the number of each cylinder, as shown in **Figure 12-2.**

Cylinder numbers are normally stamped on the connecting rods. Sometimes, they are cast into the intake manifold. Cylinder numbering varies from one manufacturer to another. You should keep this in mind when referring to engine classifications. Two V-6 engines, for example, can have completely different cylinder numbering systems.

Firing order refers to the sequence in which the cylinders fire. The position of the crankshaft rod journals in relation to each other determines engine firing order. The service manual will have a drawing showing the firing order for the engine. This information may also be given on the engine intake manifold.

It is important to note that two similar engines can have completely different firing orders. For example, a 4-cylinder, inline engine may have a firing order of 1-3-4-2 or 1-2-4-3. Firing orders for 6- and 8-cylinder engines also vary.

You must know an engine's firing order when working on the ignition system. It can be used when replacing spark plug wires, installing a distributor, or performing other tune-up related operations.

Cooling System Type

There are two types of cooling systems: liquid cooling systems and air cooling systems. The liquid cooling system is the most common. See **Figure 12-3.**

The ***liquid cooling system*** surrounds the cylinder with coolant (water and antifreeze solution). The coolant carries combustion heat out of the cylinder head and engine block to prevent engine damage.

An ***air cooling system*** circulates air over cooling fins on the cylinders. This removes heat from the cylinders to prevent overheating. Air-cooled or air-oil cooled engines are seldom used in passenger cars. They can be found on motorcycles, lawnmowers, and a few high-performance cars. With strict exhaust emission regulations, manufacturers have partially phased out air-cooled engines. Air-cooled engines cannot maintain as constant a temperature as liquid-cooled engines.

Figure 12-2. Engine cylinder numbers, distributor cap numbers, and firing order numbers can be found in the service manual. Cylinder numbers are usually stamped on the connecting rods and may be cast into the intake manifold. These numbers vary from engine to engine. (Mitchell Manuals)

Fuel Type

An engine is also classified by the type of fuel it burns. A gasoline engine burns gasoline. A diesel engine burns diesel fuel. These are the most common types of fuel for vehicles.

Liquefied petroleum gas (LPG), gasohol (10% alcohol, 90% gasoline), and pure alcohol can also be used to power an engine. These fuels are used in limited quantities.

A
B

Figure 12-3. A—Air cooling systems uses large fins around the cylinders to remove heat. B—Liquid cooling systems surround the cylinders with coolant. Liquid cooling systems are commonly used in automobiles. Motorcycles and lawnmowers use air cooling systems.

Note!
Fuels are detailed in Chapter 20, *Automotive Fuels, Gasoline and Diesel Combustion.*

Ignition Type

Two basic methods are used to ignite the fuel in an engine combustion chamber: spark ignition (spark plug) and compression ignition (compressed air).

A ***spark ignition engine*** uses an electric arc at the spark plug to ignite the fuel. The arc produces enough heat to start the fuel burning. Gasoline engines use spark ignition, **Figure 12-4A.**

A ***compression ignition engine*** squeezes the air in the combustion chamber until it is hot enough to ignite the fuel. A diesel engine is a compression ignition engine. No spark plugs are used, **Figure 12-4B.**

Valve Location

Another engine classification can be made by comparing the location of the valves.

An ***L-head engine*** has both the intake and exhaust valves in the block, **Figure 12-5A.** Also called a ***flat head engine***, its cylinder head simply forms a cover over the

Figure 12-5. Three common valve-camshaft locations. A—The valve-in-block, or L-head, engine is no longer used in automobiles. This arrangement is still used in small gas engines, such as lawnmower engines. B—The cam-in-block engine, also called the overhead valve or I-head engine, is common. C—The overhead cam engine is another form of the I-head engine. It is also very common in today's vehicles. (Black & Decker and DaimlerChrysler)

cylinders and valves. The camshaft is in the block and pushes upward to open the valves. Some four-stroke cycle lawnmower engines are L-head types. Automotive engines are no longer L-head types.

An ***I-head engine*** has both valves in the cylinder head. Another name for this design is the ***overhead valve (OHV) engine,*** **Figure 12-5B.** Numerous variations of the overhead valve engine are now in use.

Other valve configurations have been used in the past. However, they are so rare that their mention is not important.

Camshaft Location

There are two basic locations for the engine camshaft: in the block and in the cylinder head. Both locations are common.

A ***cam-in-block engine*** uses push rods to transfer motion to the rocker arms and valves, **Figure 12-5B.** The term overhead valve (OHV) is sometimes used when referring to a cam-in-block engine.

In an ***overhead cam (OHC) engine,*** the camshaft is located in the top of the cylinder head. Push rods are *not* needed to operate the rockers and valves. This type of engine is a refinement of the overhead valve engine. Refer to **Figure 12-5C.**

With the cam in the head, the number of valve train parts is reduced. This cuts the weight of the valve train. Also, the valves can be placed at an angle to improve breathing (airflow through cylinder head ports).

OHC engines were first used in racing cars to improve their high-rpm (revolutions per minute) efficiency. Now they are commonly used in small, high-rpm, car engines. With lower valve train weight, improved valve positioning, and no push rods to flex, the OHC engine is becoming very popular.

A ***single overhead cam (SOHC) engine*** has only one camshaft per cylinder head. The cam may act directly on the valves, or rocker arms may be used to transfer motion to the valves.

A ***dual overhead cam (DOHC) engine*** has two camshafts per cylinder head. One cam operates the intake valves; the other operates the exhaust valves. The dual overhead cam arrangement is frequently used in engines equipped with four-valve combustion chambers. A DOHC engine will be shown later in the chapter.

Tech Tip!
Subscribe to and read a variety of automotive magazines. They often contain technical information on the latest engine designs. This will give you valuable information when working on new vehicles.

Combustion Chamber Shape

The shape of the combustion chamber provides still another method of classifying an engine. The four basic combustion chamber shapes for gasoline engines are pancake, wedge, hemispherical, and pent-roof. These are pictured in **Figure 12-6.**

The ***pancake combustion chamber,*** also called the ***bath tub chamber,*** has valve heads that are almost parallel to the top of the piston. The chamber forms a flat pocket over the piston head, **Figure 12-6A.**

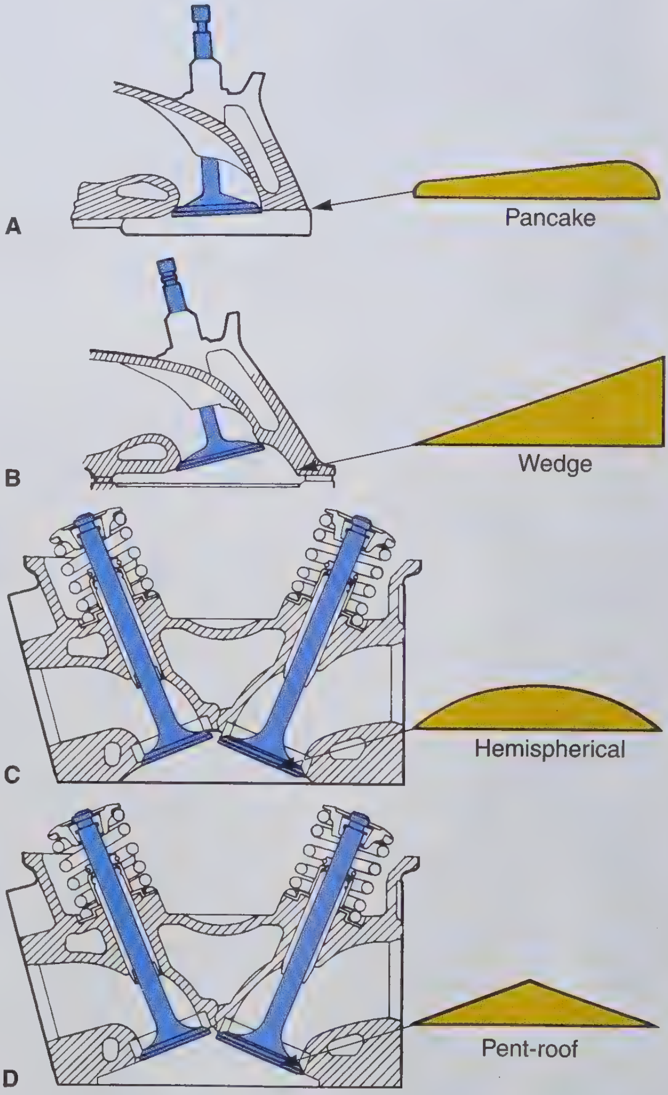

Figure 12-6. There are four basic combustion chamber shapes. A—In a pancake combustion chamber, the valves are almost parallel with the top of the piston. B—In the wedge combustion chamber, the valves are at an angle to the top of the piston. C—The valves are at an angle to each other in a hemispherical combustion chamber. D—In a pent-roof combustion chamber, the valves are located on flat, angled surfaces. (DaimlerChrysler)

A ***wedge combustion chamber,*** or ***wedge head,*** is shaped like a triangle or a wedge when viewed as in **Figure 12-6B.** Valves are placed side-by-side, and spark plug is located next to the valves.

A ***squish area*** is commonly formed inside a wedge-type cylinder head. When the piston reaches TDC, it comes very close to the bottom of the cylinder head. This squeezes the air-fuel mixture in that area and causes it to squirt, or squish, out into the main part of the chamber. Squish can be used to improve air-fuel mixing at low engine speeds.

A ***hemispherical combustion chamber***, nicknamed ***hemi-head***, is shaped like a dome. The valves are canted (tilted) on each side of the combustion chamber. The spark plug is located near the center of the chamber. A hemi-head is shown in **Figure 12-6C.** Compare it to the others.

A hemispherical combustion chamber is extremely efficient. There are no hidden pockets, minimizing the chances of incomplete combustion. The surface area is very small, reducing heat loss from the chamber. The centrally located spark plug produces a very short flame path for combustion. The canted valves help increase breathing ability.

The hemi-head was first used in high-horsepower racing engines. It is now used in many OHC passenger car engines. It allows the engine to operate at high rpm and makes it very fuel efficient. It also produces complete burning of the fuel to reduce emissions.

The **pent-roof combustion chamber** is similar to the hemispherical chamber, but it has flat, angled surfaces rather than a domed surface. This design improves volumetric efficiency and reduces emissions. See **Figure 12-6D.**

Combustion Chamber Types

Besides the four shapes just covered, there are several other combustion chamber classifications. Each type is designed to increase combustion efficiency, gas mileage, and power while reducing exhaust pollution.

A ***swirl combustion chamber*** is designed to cause the air-fuel mixture to swirl, or spin, as it enters from the intake port. Look at **Figure 12-7.** This causes the air and fuel to mix into a finer mist that burns better.

A ***four-valve combustion chamber*** uses two exhaust valves and two intake valves. This is illustrated in **Figure 12-8.** The extra valves increase flow in and out of the combustion chamber. This setup is now used on many modern passenger car engines.

In some four-valve combustion chambers, one of the intake valves is opened more than the other. This produces a swirling action on the air-fuel mixture entering the combustion chamber. The swirling action helps reduce low-speed emissions.

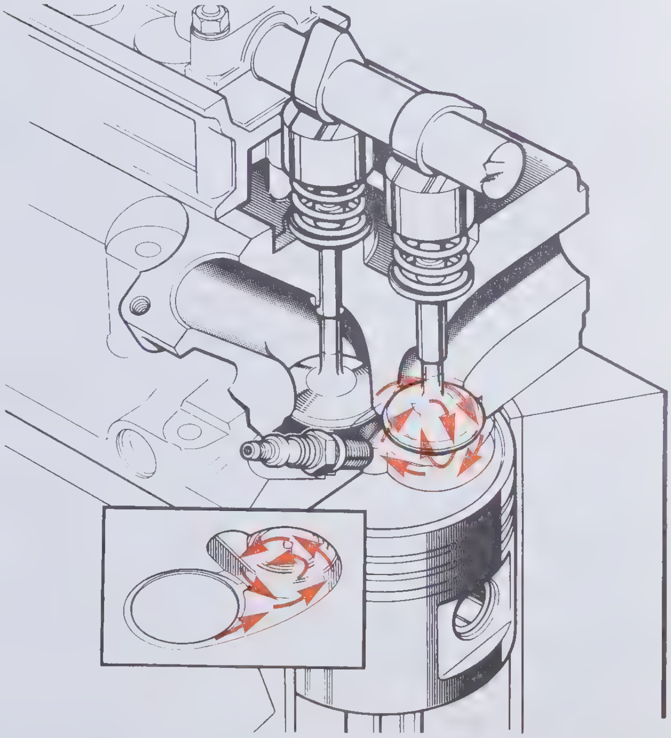

Figure 12-7. The swirl combustion chamber has a port entry designed to cause air-fuel mixture swirling. This helps stir the air and fuel into a finer mist for improved combustion. Many chambers use this principle. (Jaguar)

A ***three-valve combustion chamber*** has two intake valves and one exhaust valve. The two intake valves allow ample airflow into the combustion chamber on the intake stroke. The single exhaust valve provides enough

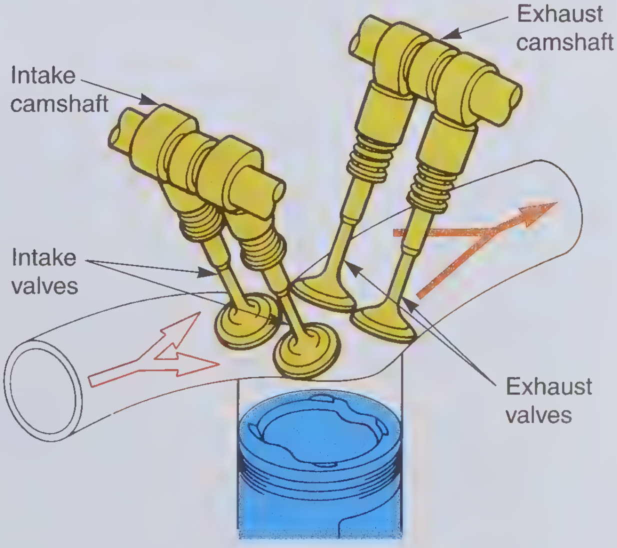

Figure 12-8. Four-valve combustion chambers are used in many late-model engines. Extra valves increase flow and engine power. (Toyota)

surface area to handle exhaust flow. This is a relatively new design and is used by only a couple manufacturers. The three-valve combustion chamber provides almost as much performance gain as a four-valve chamber, but it has fewer moving parts. This reduces cost and increases reliability.

A ***stratified charge combustion chamber*** uses a small combustion chamber flame to ignite and burn the fuel in the main, large combustion chamber. A very ***lean mixture*** (high ratio of air to fuel) is admitted into the main combustion chamber. The mixture is so lean that it will not ignite and burn easily. A *richer mixture* (higher ratio of fuel to air) is admitted into the small chamber by an extra valve. When the fuel mixture in the small chamber is ignited, flames blow into the main chamber and ignite the lean mixture.

The stratified charge chamber allows the engine to operate on a lean, high-efficiency air-fuel ratio. Fuel economy is increased, and exhaust emission output is reduced.

An ***air jet combustion chamber*** has a single combustion chamber fitted with an extra air valve. Shown in **Figure 12-9,** a passage runs from the carburetor to the combustion chamber and jet valve.

During the intake stroke, the engine camshaft opens both the conventional intake valve and the air jet valve. This allows fuel mixture to flow past the conventional intake valve and into the cylinder. At the same time, a stream of air flows into the cylinder through the jet valve.

The ***jet valve*** action causes the fuel mixture in the cylinder to swirl and mix. This increases combustion efficiency by causing more of the fuel to burn during the power stroke. The jet valve only works at idle and low engine speeds. At higher rpm, normal air-fuel mixing is adequate for efficient combustion.

A ***precombustion chamber*** is commonly used in automotive diesel engines. It is similar in shape to the stratified charge chamber used in gasoline engines. Also called a ***diesel prechamber,*** the precombustion chamber is used to quiet engine operation and to allow the use of a glow plug (heating element) to aid cold weather starting. **Figure 12-10** shows a cutaway view of a diesel prechamber.

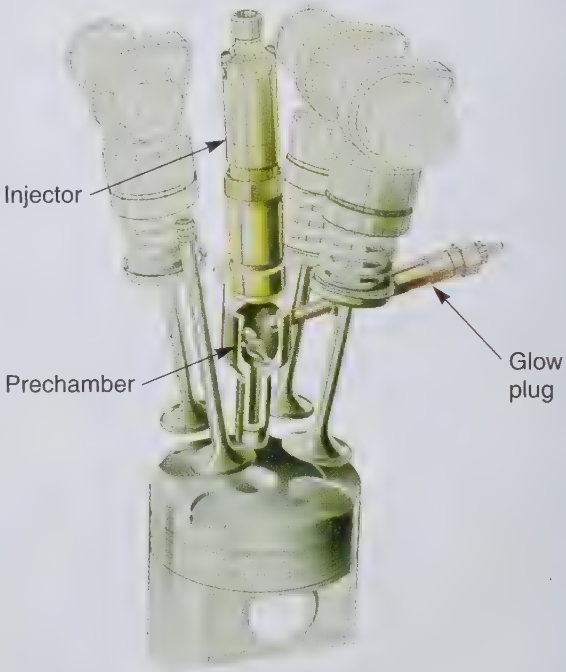

Figure 12-10. A diesel engine precombustion chamber should not be confused with a gasoline engine stratified charge chamber. The precombustion chamber quiets engine operation and allows the use of a glow plug. The glow plug is a heating element that improves cold weather starting. (General Motors)

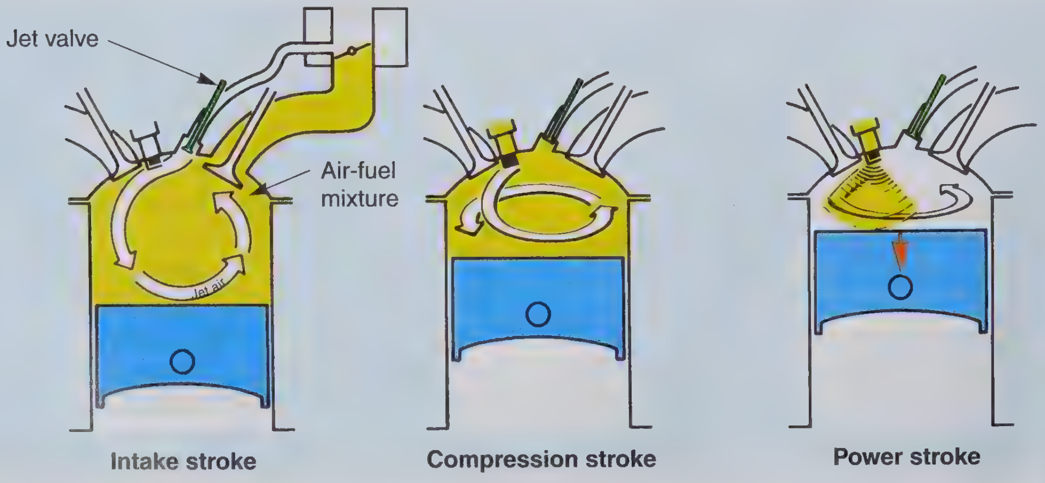

Figure 12-9. An air jet injects a stream of air into the chamber at idle to improve fuel mixing and combustion. (DaimlerChrysler)

During combustion, diesel fuel is injected into the prechamber. If the engine is cold, the glow plug heats the air in the prechamber. This heat, along with the heat produced by compression, causes the fuel to ignite and burn. As the fuel burns, the flame expands and moves into the main chamber to burn the remaining diesel fuel to produce a power stroke.

Alternative Engines

As you have learned, vehicles generally use internal combustion, 4-stroke cycle, reciprocating piston engines. ***Alternative engines*** include all other engine types that may be used to power a vehicle. Various engine types have been developed, but few have been placed into production.

Rotary Engine

A ***rotary engine,*** also known as a ***Wankel engine,*** uses a spinning triangular rotor instead of conventional pistons. The rotor turns inside a specially shaped chamber, as shown in **Figure 12-11.**

While turning in the chamber, the rotor orbits around a mainshaft. This eliminates the reciprocating (up-and-down) motion found in piston engines.

Three complete power-producing cycles take place during every revolution of the rotor: three rotor faces produce three intake, compression, power, and exhaust events per revolution. **Figure 12-12** illustrates the basic operation of a rotary engine.

A rotary engine is very powerful for its size. Also, because it spins—rather than moving up and down—engine operation is very smooth and vibration free.

A complicated emission control system is needed to make the rotary engine pass emission standards. This limited its use. The rotary engine was one of the few alternate engines to be mass-produced.

Steam Engine

A ***steam engine*** heats water to produce steam (hot water vapor). The steam pressure operates the engine pistons. Look at **Figure 12-13.**

A steam engine is an external combustion engine, since its fuel is burned outside the engine. Automotive engines are internal combustion engines because they burn fuel inside the engine.

Steam engines were used on some of the first cars. They are not used today because of their low efficiency.

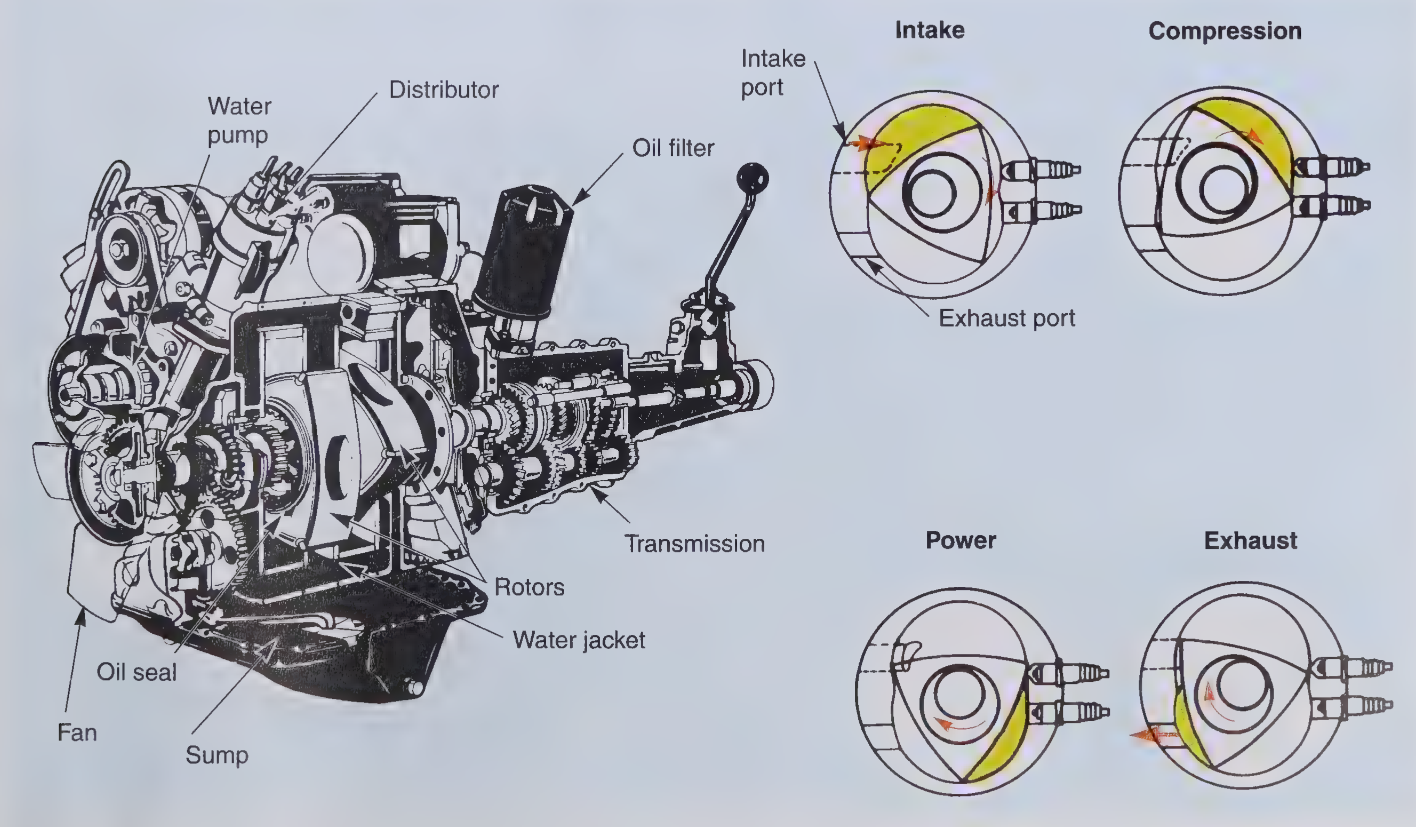

Figure 12-11. The rotary engine does not use conventional pistons, which move up and down in the cylinder. Instead, a rotor spins in circular motion. Note the engine parts. (Mazda)

Figure 12-12. In a rotary engine, rotor movement produces a low-pressure area, pulling the air-fuel mixture into the engine. As the rotor turns, the mixture is compressed and ignited. As the fuel burns, it expands and pushes on the rotor. The rotor continues to turn, and burned gases are pushed out of the engine.

Gas Turbine

The ***gas turbine*** uses burning and expanding fuel vapor to spin fan-type blades. These blades are connected to a shaft that can be used for power output. **Figure 12-14** illustrates a basic gas turbine.

Two-Stroke-Cycle Engine

A ***two-stroke-cycle engine*** is similar to a four-stroke-cycle engine, but it requires only one revolution of the crankshaft for a complete power-producing cycle. Two piston strokes (one upward and one downward) complete the intake, compression, power, and exhaust events.

Figure 12-14. A gas turbine uses pressure from burning fuel to spin fan-like blades. This motion is used to rotate the shaft and gears for power output. The gas turbine is not commonly used because of its high manufacturing costs. It requires special metals, ceramics, and precision machining and balancing. Someday, the gas turbine may be a very common automotive engine.

Figure 12-15 illustrates the basic operation of a two-stroke engine.

As the piston moves up, it compresses the air-fuel mixture in the combustion chamber. At the same time, the vacuum created in the crankcase by the piston movement draws fuel and oil into the crankcase. Either a ***reed valve*** (flexible metal flap valve) or a ***rotary valve*** (spinning disc-shaped valve) can be used to control flow into the crankcase.

When the piston reaches the top of the cylinder, ignition occurs and the burning gases force the piston downward. The reed valve or rotary valve closes, compressing and pressurizing the fuel mixture in the crankcase.

As the piston moves far enough down in the cylinder, it uncovers an exhaust port in the cylinder wall. Burned gases leave the engine through the exhaust port.

As the piston continues downward, it uncovers the transfer port. Pressure in the crankcase causes a fresh fuel charge to flow through the transfer port and into the cylinder. Upward movement of the piston again covers the transfer and exhaust ports, compression begins, and the cycle is repeated.

Since the crankcase is used as a storage chamber for each successive fuel charge, the fuel and lubricating oil are pre-mixed and introduced into the engine through the carburetor.

Inside the crankcase, some of the oil separates from the gasoline. The oil mist lubricates and protects the moving parts inside the engine.

Generally speaking, two-stroke-cycle engines are *not* used in vehicles because they:

- Produce too much exhaust pollution.
- Have poor power output at low speeds.
- Require more service than a four-stroke engine.
- Must have motor oil mixed into the fuel.
- Are not as fuel efficient as a four-stroke engine.

Miller-Cycle Engine

A ***Miller-cycle engine*** uses a modified four-stroke cycle. This engine is designed with a shorter compression stroke and a longer power stroke to increase efficiency. The intake valve remains open longer to delay compression. Because the intake valve remains open for a relatively long time, the air-fuel charge wants to be pushed back out the intake port. To compensate for this reverse flow, a supercharger is normally used to pressurize the intake manifold and block this flow, **Figures 12-16** and **17.**

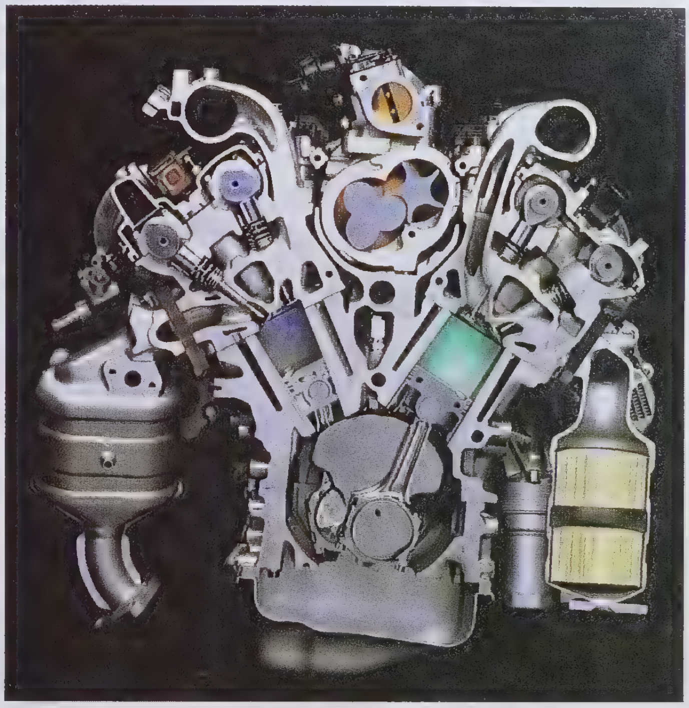

Figure 12-16. Cutaway view of a Miller-cycle engine. It is similar to a conventional four-stroke piston engine. However, the opening and closing of the intake valves is modified to increase the duration of power stroke. Note the supercharger, which is needed to prevent backflow of the fuel charge into the intake manifold. (Mazda)

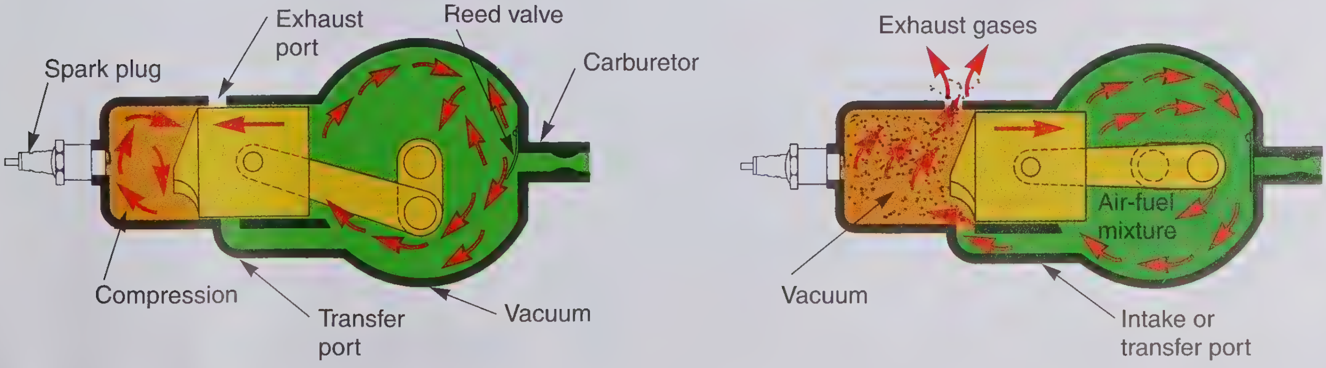

Figure 12-15. The two-stroke-cycle engine completes all four events in two piston movements. (Ethyl Corporation)

Theoretically, a Miller-cycle engine can produce more power and is more economical than a conventional four-stroke-cycle engine of equal size. However, the engine is more complex to produce and maintain because of the supercharger. One auto manufacturer is now successfully using a Miller-cycle engine in its passenger cars.

Typical Automotive Engines

Figures 12-18 through **12-28** illustrate typical automotive engines. Study each of these carefully. Note the design variations between each type. Also, study the names of all the parts. This will help you in later chapters.

Workplace Skills

An apprentice technician gave a customer a quote for a valve job on a passenger car engine. The apprentice failed to recognize that the customer's vehicle was equipped with a four-valve engine. When the bill came back from the machine shop for grinding the valves and cylinder head seats, it was twice as much as estimated. Instead of 16 valves, the heads had 32 valves and 32 seats, doubling the parts and labor needed to recondition the heads.

The apprentice tried to explain to the customer why the final bill for the repair was higher than originally estimated. The customer paid the bill, but he left the shop angry, vowing never to return.

If the apprentice had taken the time to learn about various engine classifications, he would not have given the low quote and the customer would have been satisfied with the repair. If you are not sure about something, research it.

Summary

- Although basic engine parts are the same, design differences can change how engines operate and how they are repaired.
- Cylinder arrangement refers to the position of the cylinders in relation to the crankshaft.
- Firing order refers to the sequence in which combustion occurs in each engine cylinder.
- The liquid cooling system surrounds the cylinder with coolant (water and antifreeze solution).
- A spark ignition engine uses an electric arc at the spark plug to ignite the fuel.
- A compression ignition engine squeezes the air in the combustion chamber until it is hot enough to ignite the fuel.
- A cam-in-block engine uses push rods to transfer motion to the rocker arms and valves.
- In an overhead cam (OHC) engine, the camshaft is located in the top of the cylinder head.

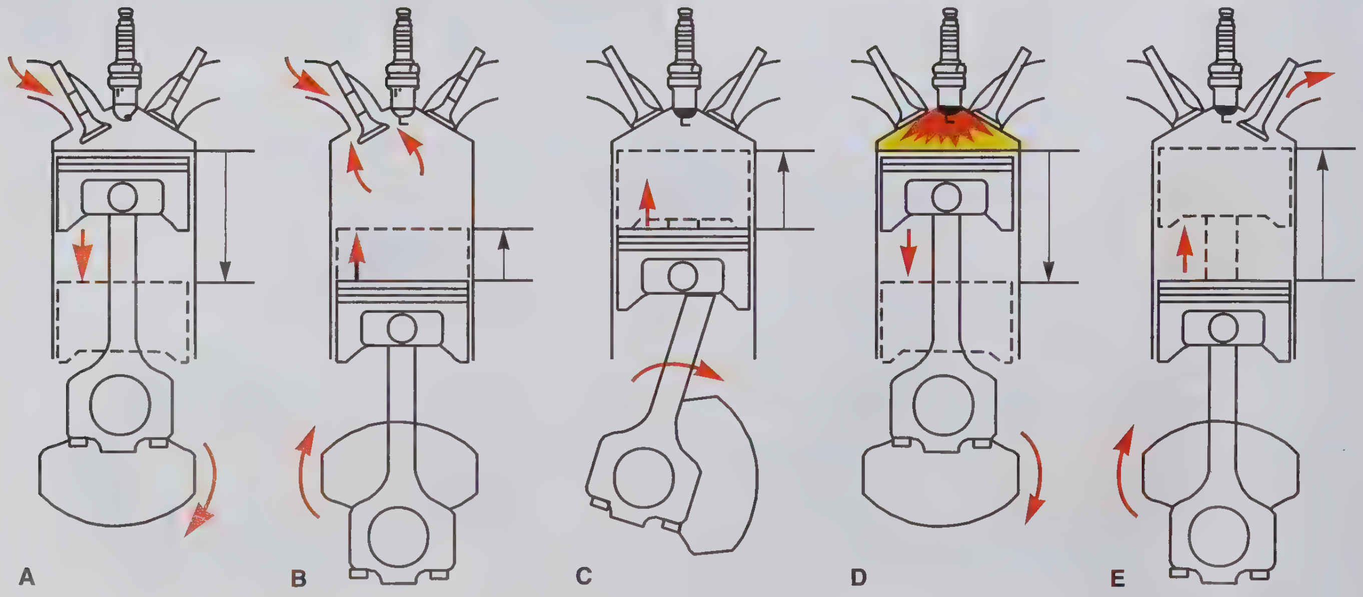

Figure 12-17. Illustrations show Miller-cycle engine operation. A—The piston slides down with the intake valve open. B—The intake valve remains open as the piston slides up. Supercharger pressure prevents backflow into the intake port. C—Piston travels with both valves closed. D—Power stroke. E—Exhaust stroke.

- A four-valve combustion chamber uses two exhaust valves and two intake valves per cylinder.
- A stratified charge combustion chamber uses a small combustion chamber flame to ignite and burn the fuel in the main combustion chamber.
- A precombustion chamber is commonly used in automotive diesel engines.
- Alternative engines include all engine types that can be used to power a vehicle except four-stroke-cycle, reciprocating piston engines.
- The gas turbine uses burning and expanding fuel vapor to spin fan-type blades.
- A two-stroke-cycle engine is similar to a four-stroke-cycle engine, but it requires only one revolution of the crankshaft for a complete power-producing cycle.

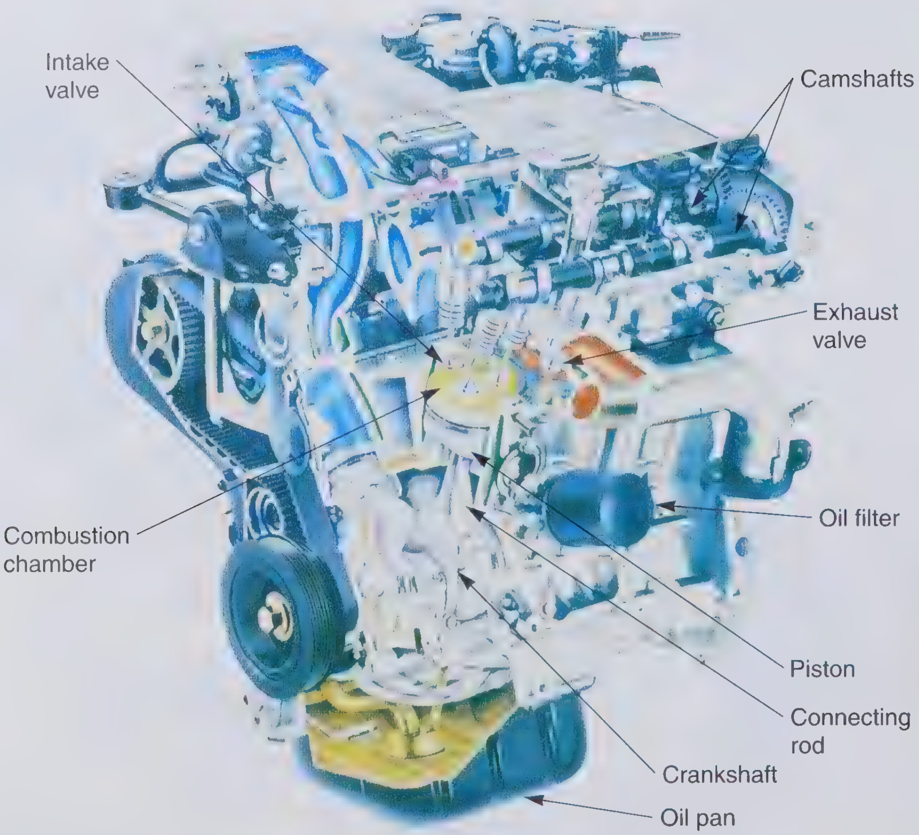
Review Questions—Chapter 12

Please do not write in this text. Place your answers on a separate sheet of paper.

1. List ten ways to classify an automotive engine.
2. Normally, car engines have _____, _____, or _____ cylinders.
3. Why are cylinders numbered?
4. Firing order refers to the _____ in which the spark plugs fire in the combustion chambers.
5. Most car engines have air cooling systems. True or False?
6. Explain the difference between spark ignition and compression ignition.



Intake valve
Camshafts
Exhaust valve
Combustion chamber
Oil filter
Piston
Connecting rod
Crankshaft
Oil pan

Figure 12-22. DOHC V-6 engine. Each cylinder head contains two camshafts—one to operate the intake valves and another to operate the exhaust valves. (Lexus)

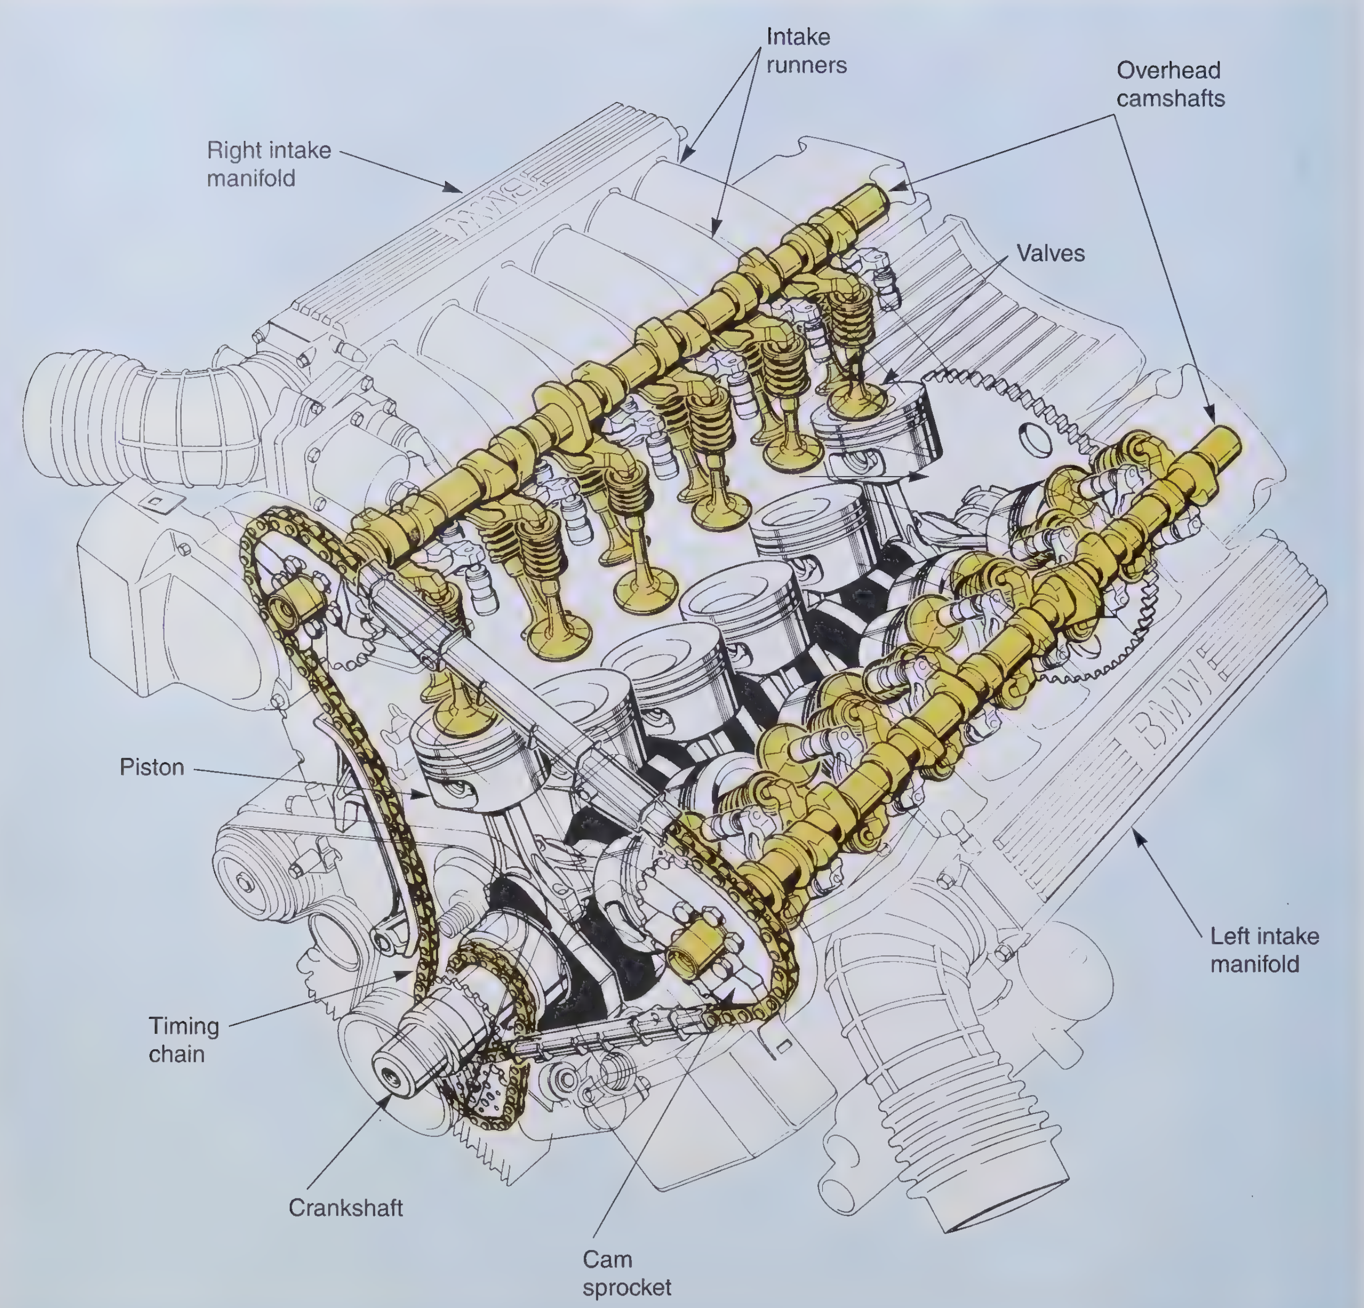
7. Where are the two typical locations for the engine camshaft?
8. Which of the following does *not* refer to camshaft location and design?
   (A) OHC.
   (B) SOHC.
   (C) DOHC.
   (D) UHC.
9. A hemi-head combustion chamber is flat. True or False?
10. Explain the operation of a diesel precombustion chamber.
11. A(n) _____ engine does *not* use pistons that slide up and down.
12. How does a gas turbine differ from a conventional piston engine?
13. Three complete power-producing cycles occur during every revolution of a rotary engine's rotor. If an engine has three rotors and each completes one revolution, how many complete cycles are produced?
   (A) 4.
   (B) 3.
   (C) 6.
   (D) 9.
14. Which of the following refers to a two-stroke-cycle engine?
   (A) One crankshaft revolution completes a power stroke.
   (B) Two strokes complete all four events.
   (C) Uses reed valves or rotary valves.
   (D) All of the above.
15. In a Miller-cycle engine, a supercharger is used to _____ the intake manifold.



Intake runners
Overhead camshafts
Right intake manifold
Valves
Piston
Left intake manifold
Timing chain
Crankshaft
Cam sprocket
BMW

Figure 12-25. Study the construction of this high-performance V-12 engine. Two roller chains are used to drive the overhead camshafts. Twelve cylinders make this a very smooth-running engine because of the relatively high number of power strokes per crankshaft revolution. (BMW)

ASE-Type Questions

1. Vehicle engine classifications include each of the following *except:*
   - *(A) valve location.*
   - *(B) type of ignition.*
   - *(C) number of cylinders.*
   - *(D) type of drive mechanism.*
2. Which of the following is *not* a basic cylinder arrangement?
   - *(A) Slant.*
   - *(B) Inline.*
   - *(C) U-type.*
   - *(D) V-type.*
3. A 4-cylinder, inline engine's firing order will be:
   - *(A) 1-3-4-2.*
   - *(B) 1-2-4-3.*
   - *(C) 1-2-3-4.*
   - *(D) Either A or B.*
4. The type of engine that has both an intake and exhaust valve in its cylinder head is called a(n):
   - *(A) I-head engine.*
   - *(B) L-head engine.*
   - *(C) flat head engine.*
   - *(D) All of the above.*
5. In an overhead cam engine, push rods are not needed to operate the:
   - *(A) rockers and valves.*
   - *(B) camshaft and valves.*
   - *(C) camshaft and rockers.*
   - *(D) All the above.*
6. The combustion chamber shape in which the valve heads are almost parallel with the top of the piston is called the:
   - *(A) swirl chamber.*
   - *(B) wedge chamber.*
   - *(C) pancake chamber.*
   - *(D) stratified chamber.*
7. Which of the following combustion chambers allows the use of a glow plug in automotive diesel engines?
   - *(A) Precombustion chamber.*
   - *(B) Swirl chamber.*
   - *(C) Air jet chamber.*
   - *(D) Stratified charge chamber.*
8. The engine type that uses a triangular rotor instead of conventional pistons is called a:
   - *(A) rotary engine.*
   - *(B) opposed engine.*
   - *(C) cam-in-block engine.*
   - *(D) spark ignition engine.*
9. A two-stroke-cycle engine requires how many crankshaft revolutions per power cycle?
   - *(A) One.*
   - *(B) Two.*
   - *(C) Four.*
   - *(D) None of the above.*
10. While discussing engines, Technician A says two-stroke-cycle engines are not used in vehicles because they have poor power output at low speeds. Technician B says two-stroke engines are not used in vehicles because they produce too much exhaust pollution. Who is right?
    - *(A) A only.*
    - *(B) B only.*
    - *(C) Both A and B.*
    - *(D) Neither A nor B.*

Activities for Chapter 12

1. Make a poster that shows the four types of engine cylinder arrangements. Label the arrangements.
2. Visit an auto dealership and identify the different engine types offered as standard across the range of automobile models under a single brand name (Ford, Honda, Chrysler, Volvo, etc.). Write a short report on your findings.
3. Find out about the Stanley Steamer or another steam-driven automobile. Describe to the class how its engine worked. Show a drawing or photograph, if possible.

13

Engine Top End Construction

After studying this chapter, you will be able to:

- Describe the design and construction of an engine cylinder head.
- Explain umbrella and O-ring type oil seals.
- Explain the purpose of valve spring shims, rotators, stem caps, and spring shields.
- Describe the construction and operation of a camshaft.
- Explain hydraulic and mechanical lifters.
- Describe different types of rocker arm assemblies.
- Explain the construction and design of intake and exhaust manifolds.
- Describe safety practices used when working on engine top end components.
- Answer ASE certification test questions that require a knowledge of engine top end construction.

An ***engine top end*** basically includes the cylinder head, valve train, valve cover, and intake and exhaust manifolds, **Figure 13-1.** Understanding the construction of an engine top end helps improve your ability to troubleshoot and repair an engine. This chapter explains the engine top end and each of its components.

Cylinder Head Construction

A ***bare cylinder head*** is a cylinder head with all of its parts removed. These parts include the valves, keepers, retainers, springs, seals, and rocker arms. A bare cylinder

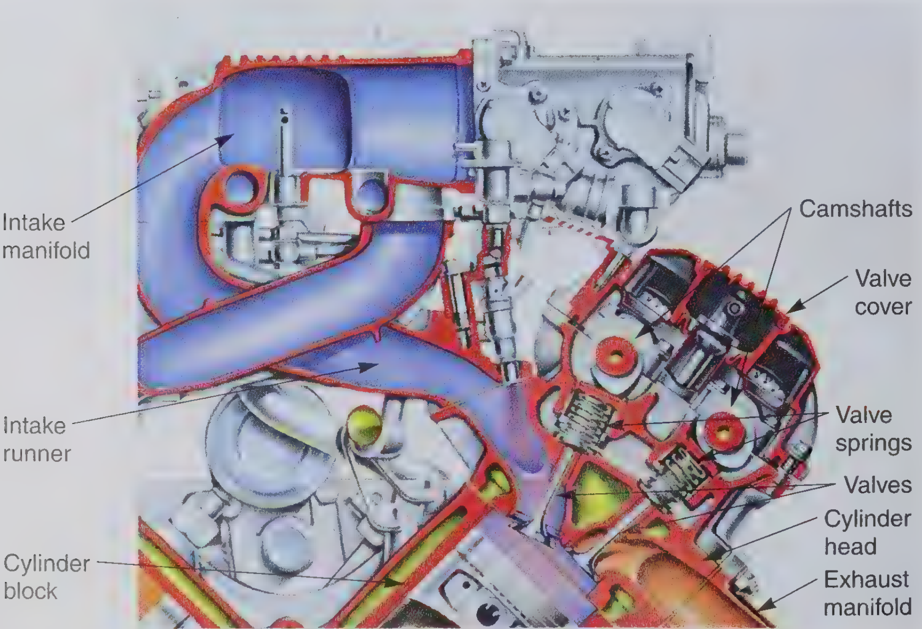


Figure 13-1. Generally, an engine top end includes parts that fasten to top of cylinder block. These include the head, valve train, intake manifold, exhaust manifold, and valve cover. (Honda)

head is commonly made of cast iron or aluminum. The parts that fit in or on a bare cylinder head (cam-in-block type) are pictured in **Figure 13-2.**

If a cylinder head becomes badly damaged, the technician may need to install a new bare head. All of the old, reusable parts (valves, keepers, retainers, etc.) can be removed and installed in the new head.

The construction of a cylinder head varies with engine design and type. It is critical that you understand the most important cylinder head variations. See **Figures 13-3** and **13-4.**

For example, some engines have a drain hole at the rear of the cylinder head. This allows the oil from the valve train to flow back down through the engine and into the sump. With this design, the engine may be mounted in the vehicle at a slight angle.

Valve Guide Construction

There are two basic types of valve guides: integral guides and pressed-in guides. Both types are used in modern engines.

An ***integral valve guide*** is part of the cylinder head casting. One is shown in **Figure 13-5.** An integral guide is simply a hole machined through the cylinder head. This type of guide is very common because of its low production cost.

A ***pressed-in valve guide*** is a separate sleeve forced into a hole machined in the cylinder head. It can be made of cast iron or bronze. Look at **Figure 13-5.** Friction from the press fit holds the valve guide in the cylinder head. A pressed-in valve guide simplifies guide repair. A worn guide can be pressed out and a new guide can be quickly

Figure 13-5. Valve guides and seats can be made as an integral part of the head or as separate inserts.

pressed in. This eliminates some of the machining needed when replacing a badly worn integral-type guide.

Valve Seat Construction

Like valve guides, valve seats can be integral or pressed-in. Both are commonly used in modern engines.

An ***integral valve seat*** is simply a machined portion of the cylinder head casting. Different cutters are used to machine a precise face on the valve port opening.

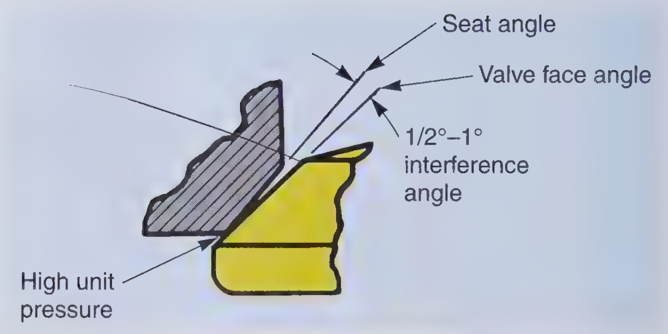
A ***pressed-in valve seat,*** also called a ***seat insert,*** is a separate part that is forced into a recess cut into the head. Steel inserts are commonly used in aluminum cylinder heads. Steel is needed to withstand the extreme heat produced during engine operation. A pressed-in valve seat is shown in **Figure 13-5.**

The ***valve seat angle*** is the angle formed by the face of the seat. A 45° angle is commonly used on passenger car engines. However, some high-performance engines have seat angles of 30°.

An ***interference angle*** is a 1/2°–1° difference between the valve seat face angle and the angle of the valve face, **Figure 13-6.** The interference angle reduces the contact area between the seat and valve. This increases pressure between the two and speeds valve seating (sealing) during engine operation.

Diesel Prechamber Cup

A ***prechamber cup*** is pressed into the cylinder head of some diesel engines. Refer to **Figure 13-7.** Holes are precisely machined into the cylinder head deck surface. The prechambers are force-fit into these holes. Each prechamber forms an enclosure around the tip of an injector and glow plug. This area is heated by the glow plug for better cold starting.



Seat angle

Exhaust valves

Figure 13-7. A diesel cylinder head normally has pressed-in prechamber cups. They form the precombustion chambers for the tips of glow plugs and injectors. (General Motors)

Stratified Charge Chamber

A ***stratified charge chamber*** also fits into the cylinder head casting. It is found in gasoline engines that are designed to use a rich fuel mixture in the auxiliary chamber to ignite a lean mixture in the main combustion chamber. **Figure 13-8** shows how the stratified charge chamber and related components are assembled in the cylinder head. Study it closely.

Note!
For more information on stratified charge chambers, refer to Chapter 12, *Engine Design Classifications.*

Valve Train Construction

The valve train controls the opening and closing of the cylinder head ports. Although the basic function of all valve trains is the same, valve train construction will vary with engine design. To be able to work on any type of valve train, you must understand these differences.

Valve Construction

Automotive engines commonly use ***poppet valves,*** or ***mushroom valves.*** These terms come from the valve's shape and action. The valve is shaped something like a mushroom and it "pops" open. Several engine valves are shown in **Figure 13-9.**

Almost every surface of a valve is machined. The stem must accurately fit the guide. Some engine valve stems are chrome plated to better resist wear. The face must contact the seat perfectly. The margin must be thick enough to prevent valve burning. Grooves are cut into the valve stem tops for the keepers.

The ***valve face angle*** is the angle formed between the valve face and valve head. Normal valve face angles are 45° and 30°. The exhaust valve is exposed to higher temperatures than the intake valve—the intake valve has cooler outside air flowing over it, while hot combustion gases flow over the exhaust valve. If the exhaust valve does not transfer heat into the cylinder head, it will burn.

Hollow-stem, ***sodium-filled valves*** are used when extra valve cooling action is needed. Refer to **Figure 13-9C.** During engine operation, the sodium inside the hollow valve melts. When the valve is pressed down, or opened, the sodium splashes down into the valve head and collects heat. Then, when the valve is released, or closed, the sodium splashes up into the valve stem. Heat transfers out of the sodium and into the stem, valve guide, and engine coolant. In this way, the valve is cooled.

A ***stellite valve*** has a stellite (very hard metal alloy) coating on its face. A stellite coating is often used in engines designed to burn unleaded fuel. Older engines

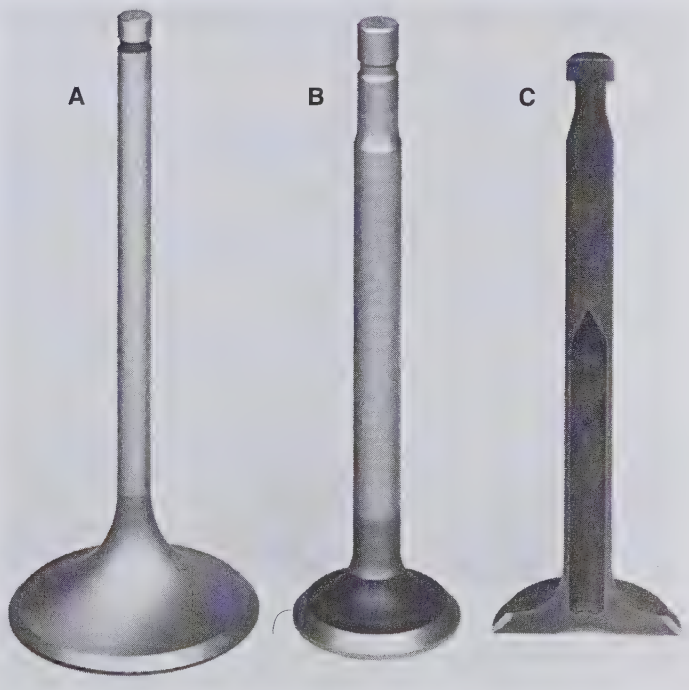

Figure 13-9. Three typical engine valves. A—Polished intake valve. B—Stock exhaust valve. C—Hollow exhaust valve designed to hold sodium for cooling. (Dana)

did not require the use of stellite valves, because leaded fuel (now phased out) helped lubricate the valve and seat faces. Look at **Figure 13-10.**

Warning!
Sodium-filled valves are used in a few high-performance engines. They are very light and allow high engine rpm for prolonged periods. However, they can explode if placed in a fire and, therefore, must be disposed of properly.

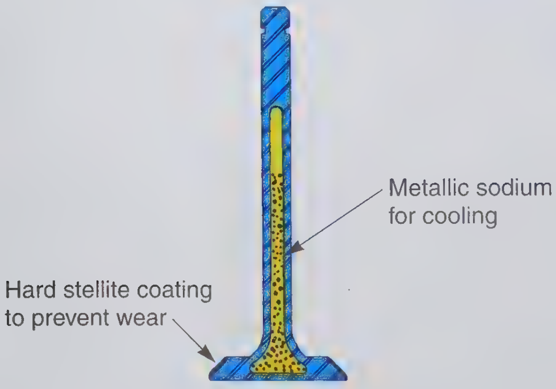
Valve Seal Construction

Valve seals come in two basic types. These types are umbrella and O-ring. Both are common on modern engines.

An ***umbrella valve seal*** is shaped like a cup and can be made of neoprene rubber or plastic. Three are shown in **Figure 13-11.** An umbrella valve seal slides down over the valve stem before the spring and retainer. It covers the small clearance between the valve stem and guide. This keeps oil from being drawn into the cylinder head port and combustion chamber.

An ***O-ring valve seal*** is a small round seal that fits into an extra groove cut in the valve stem. Look at **Figure 13-12.** Unlike the umbrella type, it seals the gap between the retainer and valve stem, not the guide and stem. It stops oil from flowing through the retainer, down the stem, and into the guide. An O-ring valve seal fits onto the valve stem *after* the spring and retainer. It is made of soft synthetic rubber that allows it to be stretched over the valve stem and into place.

A ***valve spring shield*** is normally used with an O-ring type oil seal. The shield surrounds the top and upper sides of the spring and helps keep oil off the valve stem. See **Figure 13-12.** A ***nylon shedder*** can also be used to limit the amount of oil that splashes on the valve stem and guide opening. One is illustrated in **Figure 13-13.** The shedder is a cross between a conventional oil seal and a valve spring shield. It seals against the valve stem like a seal and encircles the upper spring like a shield.



Metallic sodium for cooling
Hard stellite coating to prevent wear

Figure 13-10. Stellite coating on the valve face retards wear and allows the use of unleaded fuel.

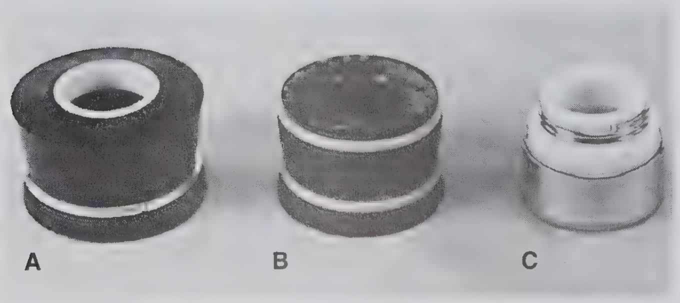


Figure 13-11. Umbrella valve seals form a covering over the opening at the top of valve guides. A—Synthetic rubber seal with a plastic shedder insert. B—All synthetic rubber seal. C—Plastic valve seal.

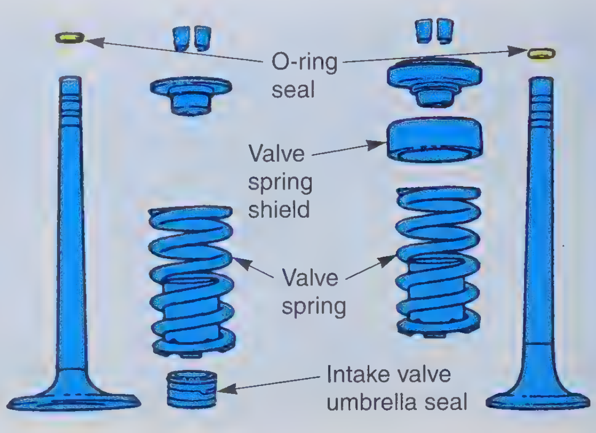

Figure 13-12. O-ring valve seal fits into an extra groove cut into the valve stem. To prevent seal damage, the spring and retainer must be installed before the seal. This valve spring assembly uses both an O-ring seal and an umbrella seal on the intake valve. (Buick)

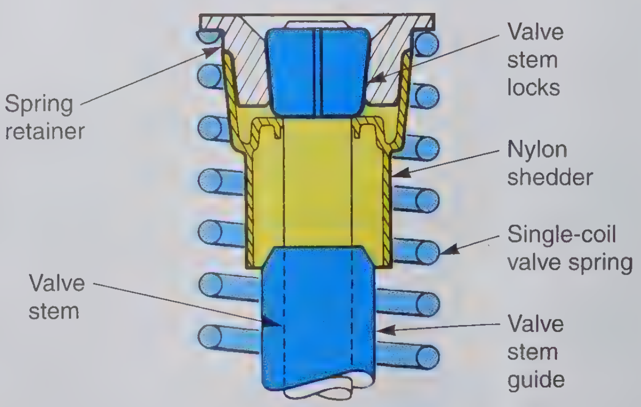

Figure 13-13. A nylon shedder functions as both an O-ring seal and a shield to keep oil out of the valve guide. (Cadillac)

Valve Spring Construction

Valve spring construction is basically the same for all engines. However, the number and type of coils can vary. **Figure 13-13** shows single coil valve springs. **Figure 13-14** shows a valve spring with an inner and outer coil. The second coil increases the amount of pressure holding the valve closed.

Spring tension refers to the stiffness of a valve spring measured in psi or kPa. Spring tension is usually stated for both opened and closed valve positions. The service manual will give the tension in pounds or kilograms for specific compressed lengths.

Spring free length is the length of the valve spring when removed from the engine. ***Spring open length*** is the spring's length when installed on the engine with the valve fully open. ***Spring closed length*** is the length of the valve spring when installed on the engine with the valve closed. Both open length and closed length are measured from the bottom of the spring to the bottom of the spring retainer.

Spring specifications are important. They affect valve action. Low spring tension can cause valve float. ***Valve float*** occurs when the valve fails to close entirely at high rpms because the spring is too weak.

Valve Spring Shim

A ***valve spring shim*** is a very thin, accurately machined washer used to increase spring tension. When a shim is placed under a spring, the open and closed lengths of the valve spring are reduced. This compresses the spring to increase closing pressure. A used valve spring may weaken and lose some of its tension. Valve spring shims provide a means of restoring full spring tension and pressure without spring replacement.

Note!
Selection and installation of valve spring shims is covered in Chapter 51, *Engine Top End Service.*

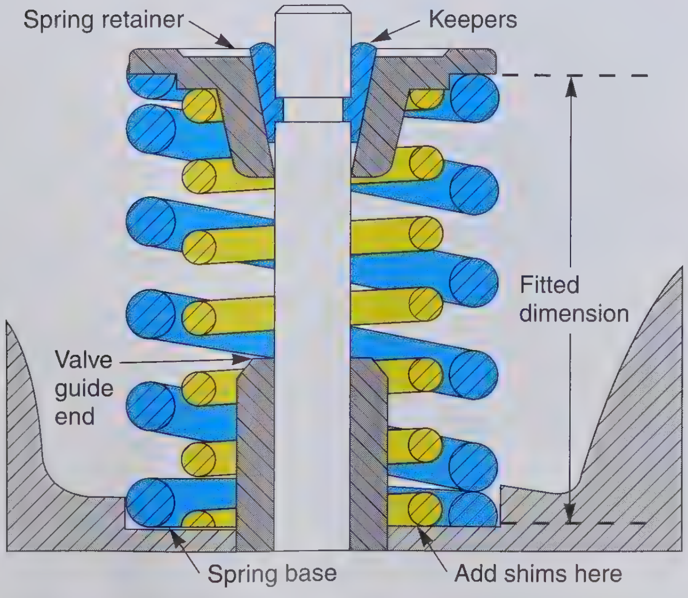

Figure 13-14. A dual-coil valve spring increases the valve closing pressure. Also notice the other parts. (Ford)

Valve Retainers and Keepers

Valve retainers and ***keepers*** lock the valve spring onto the valve. The retainer is a specially-shaped washer that fits over the top of the valve spring. The keepers fit into the valve stem grooves. This holds the retainer and spring in place. Refer to **Figures 13-14** and **13-15.**

Valve Spring Seat

A ***valve spring seat*** is a cup-shaped washer installed between the cylinder head and the bottom of the valve spring. It provides a pocket to hold the bottom of the valve spring, as shown in **Figure 13-15.**

Valve Rotators

A ***valve rotator*** turns the valve to prevent carbon buildup and hot spots on the valve face. A valve rotator may be located under or on top of the valve spring. If under the seat, it is called a ***seat-type rotator.*** If on top of

the valve spring, it is called a ***retainer-type rotator.*** Rotators are commonly used on engine exhaust valves, which are exposed to more heat than intake valves. See **Figure 13-16.**

Valve Stem Cap

A ***valve stem cap*** may be placed over the end of the valve stem. It helps prevent stem and rocker arm wear. A valve stem cap is free to turn on the valve stem. This serves as a bearing that reduces friction. Some valve stem caps are used to adjust the clearance in the valve train. Different cap thicknesses are available. Caps can be changed to alter the clearance between the rocker arm and the valve stem.

Camshaft Construction

A ***camshaft*** controls when the valves open and close. It can be driven by gears, a chain, or a belt. The number of lobes on a camshaft depends on the number of valves in the combustion chambers and the number of cylinders in the engine. Many engines only use one camshaft. However, others use two or more, **Figure 13-17.**

With dual overhead cam engines, there are two camshafts. One is the intake camshaft and the other is the exhaust camshaft. The ***intake camshaft*** operates all the intake valves in the cylinder head. The ***exhaust camshaft*** operates all the exhaust valves.

Cam Lobes

The ***cam lobes*** are precision-machined and polished surfaces on the camshaft. Each cam lobe consists of a nose, flank, heel, and base diameter, as shown in **Figure 13-18.** Variations in lobe shape control:

- When each valve opens in relation to piston position.
- How long each valve stays open.
- How far each valve opens.

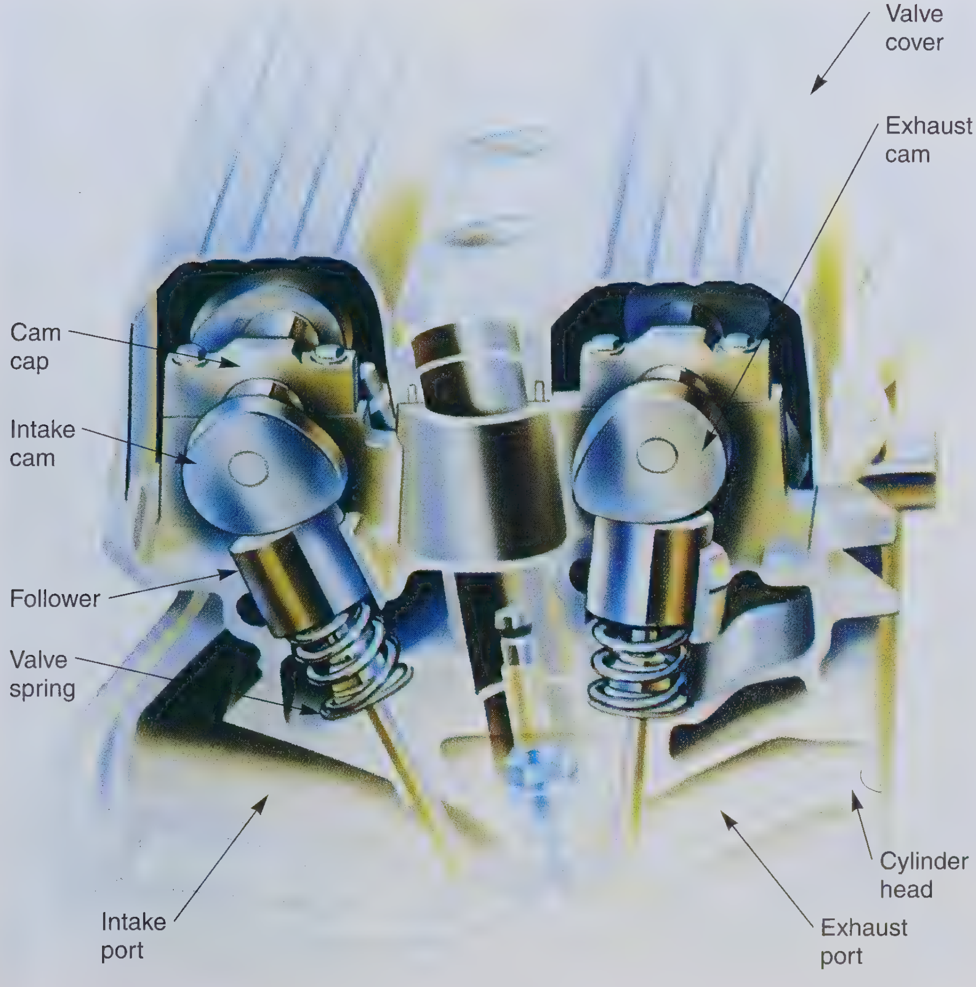

Figure 13-17. In a dual overhead cam engine, separate camshafts control the intake and exhaust valves. The shape of the cam lobes determines when the valves open, how far they open, and how long they remain open. (General Motors)

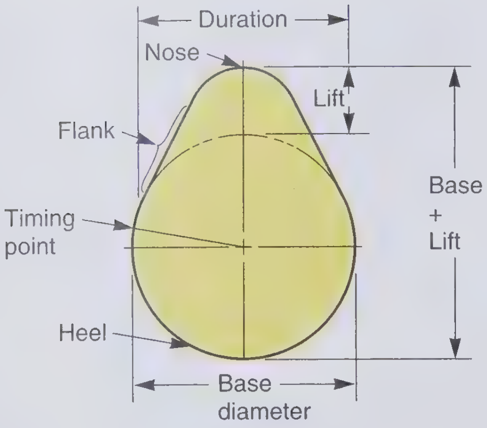

Figure 13-18. The basic parts and shape of a cam lobe. The height of the nose compared to base circle determines the amount of valve opening. The width or roundness of the nose determines how long valve stays open. (TRW)

Camshaft lift is the distance the valve opens. See **Figure 13-18.** Camshaft lift is found by subtracting the cam base diameter from the height of the cam lobe.

Camshaft duration determines how long the valve stays open. The shape of the cam lobe nose and flank regulates camshaft duration. For instance, a pointed cam lobe has a shorter duration than a rounded lobe.

Valve timing refers to valve opening and closing in relation to the position of the pistons in the cylinders. Valve timing is designed into the camshaft and drive sprockets or gears by the manufacturer.

Variable valve timing means that the engine can alter *when* the valves open with engine speed. Various mechanisms are used to provide variable valve timing. Some engines use an extra cam lobe that functions at high speeds. Others use electromechanical or hydraulic devices on the camshaft sprockets to advance or retard the cams.

Valve overlap is the time when both the intake and exhaust valves in the same cylinder are open. Look at **Figure 13-19.** Valve overlap is used to help draw burned gases out of the cylinder. It also helps pull a fresh fuel charge into the cylinder. With both the intake and exhaust valves open, there is more flow into and out of the combustion chamber. The added flow of air-fuel mixture and exhaust gases increases engine power. Valve overlap helps engine breathing, especially at higher engine speeds.

Some camshafts are machined with ***dual cam lobes*** that have two different profile shapes. One cam lobe is designed for good low-speed efficiency. The other is a high-speed profile for high engine rpm power. The driveline control module operates a solenoid valve that controls oil flow to shift the rocker arms from one lobe profile to the other.

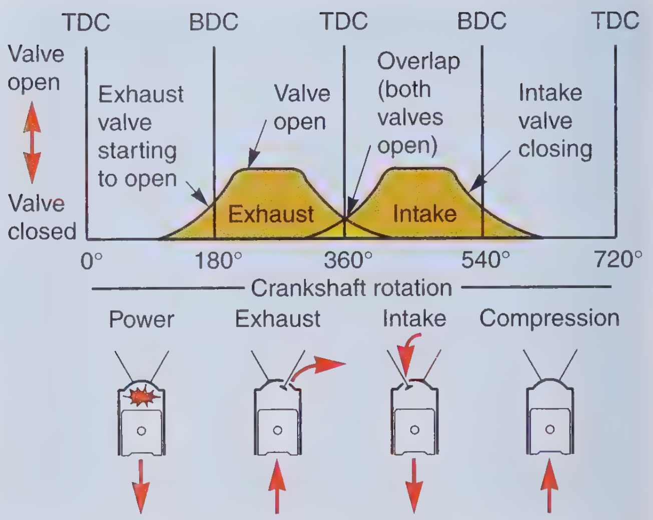

Figure 13-19. Valve timing is the measurement of when valves open in relation to the piston position in the cylinder. Valve overlap is the period where both the intake and exhaust valves in the same cylinder are open. (VW)

Hollow camshafts can have their lobes pressed onto the shaft. To lock the splined lobes in place, an oversize steel ball is forced down through the center of the hollow shaft. Some new engines use hollow composite camshafts to lighten the valve train for quicker engine acceleration.

Camshaft Thrust Plate

A ***camshaft thrust plate*** is used to limit camshaft end play. End play is the front-to-rear movement. The thrust plate bolts to the front of the block or cylinder head. When the drive gear or sprocket is bolted in place, the thrust plate sets up a predetermined camshaft end play.

Cam Bearings

Cam bearings are usually one-piece inserts pressed into the block or cylinder head. See **Figure 13-20.** Two-piece inserts are sometimes used when the camshaft is mounted in the head. The camshaft journals ride in the cam bearings. Cam bearings are usually constructed like engine main and connecting rod bearings.

Note!
For more information on this subject, refer to Chapter 14, *Engine Bottom End Construction.*

Cam Housing and Cam Cover

A ***cam housing*** is a casting that bolts to the top of the cylinder head to hold the engine camshaft. It is used in some overhead cam engine designs. A ***cam cover*** is a lid over the top of the cam housing. It serves the same purpose

Figure 13-20. Camshaft journals ride in cam bearings. Cam bearings may be pressed into the block or cylinder head bore. (Federal Mogul)

as a valve cover on an overhead valve engine. Acoustically dampened construction means the part is designed to help reduce the transmission of sound. For example, some head or valve covers are acoustically dampened by making them out of two sheets of steel formed around a center layer of sound-dampening material.

Valve Lifters

Valve lifters, or ***tappets,*** ride on the camshaft lobes and transfer motion to the other parts of the valve train. Look at **Figure 13-21.** The bottom of a lifter is crowned, or slightly curved. The camshaft lobe is also not perfectly square with the lifter base. As a result, one side of the lifter touches the cam lobe. This tends to rotate the lifter in its bore to reduce wear. There are four basic types of lifters. These are hydraulic, mechanical, roller, and OHC follower.

Hydraulic valve lifters are common because they operate *quietly* by maintaining zero valve clearance. Zero valve clearance means that there is no space between valve train parts. With zero clearance, the valve train does not clatter when the engine is running. The hydraulic lifter adjusts automatically with temperature changes and part wear. Look at **Figure 13-22**. During engine operation, oil

pressure fills the inside of the hydraulic lifter with motor oil, **Figure 13-23.** The pressure pushes the lifter plunger up in its bore until all the play is out of the valve train. As the camshaft pushes on the lifter, the lifter check valve closes to seal oil inside the lifter. Since oil is *not* compressible, the lifter acts as a solid unit to open the valve.

Mechanical lifters, also called ***solid lifters,*** do not contain oil. They simply transfer cam lobe action to the push rod. Mechanical lifters are *not* self-adjusting and require periodic setting. A screw adjustment is normally provided at the rocker arm when solid lifters are used. Turning the adjustment screw down reduces any "play" in the valve train. Unscrewing, or backing off, the rocker arm adjustment increases clearance. The small clearance needed with solid lifters causes valve train noise. A clattering or clicking noise is produced as the valves open and close. See **Figure 13-24.**

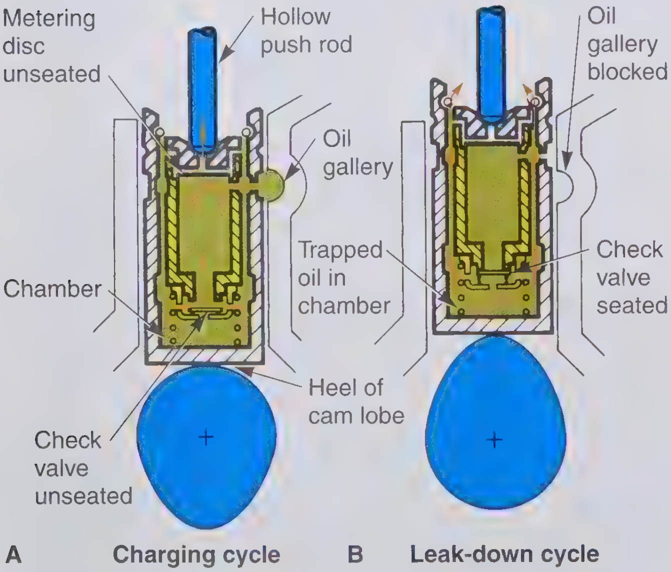

Figure 13-23. A—When the valve closes, oil rushes into the lifter, pushing up on the disc or plunger to maintain zero clearance. B—When the cam acts on the lifter, oil is trapped in the lifter by a check valve. The lifter acts as a solid unit to push the valve open. (DaimlerChrysler)

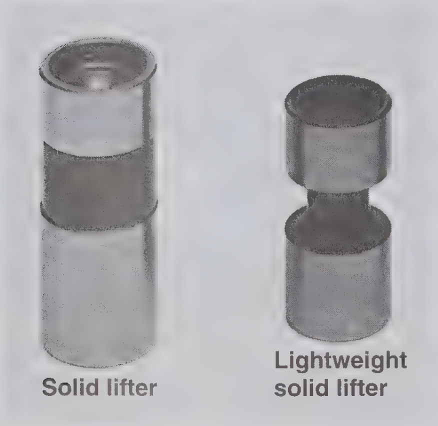

Figure 13-24. Typical mechanical, or solid, lifters.

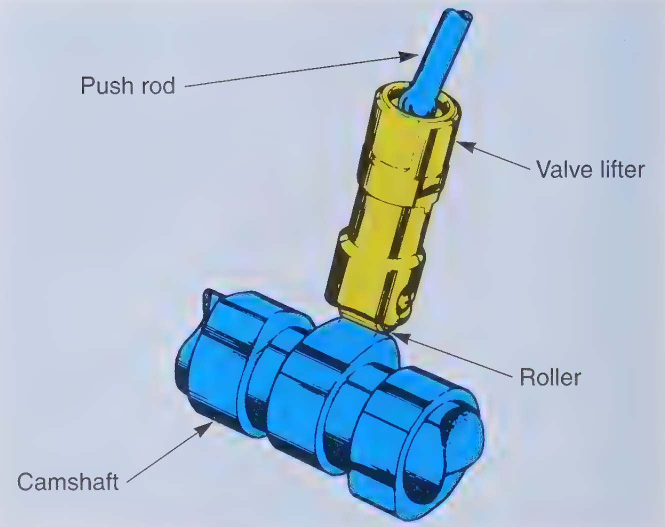

Figure 13-25. A roller lifter is commonly used in diesel engines to reduce friction. The roller spins as the camshaft rotates. (General Motors)

A ***roller lifter*** has a small roller that rides on the camshaft lobe, **Figure 13-25.** This type of lifter can be either mechanical or hydraulic. The point where the lifter touches the camshaft is one of the highest friction points in the engine. The roller helps reduce this friction and wear. A roller lifter is also used to reduce frictional losses of power.

An ***OHC follower*** fits between the camshaft and valve, **Figure 13-26.** The follower slides up and down in a bore machined in the head. Either an adjusting screw in the follower or shims of different thicknesses can be used to adjust valve clearance.

Push Rod Construction

Push rods are metal tubes or rods with specially formed ends. They are used in cam-in-block engines to transfer motion from the lifters to the rocker arms, **Figure 13-27A.** Some push rods have a ball on each end. Others have a ball on one end and a female socket on the other end. Some hollow push rods have holes in the ends to feed oil from the lifter to the rocker arms. This prevents wear on the tip of the push rod and on the rocker arm.

In some engines, ***push rod guide plates*** are used to limit side movement of the push rods. See **Figure 13-27B.** The guides hold the push rods in alignment with the

rocker arms. When the push rods pass through holes in the cylinder head or intake manifold, guide plates are *not* needed.

Rocker Arm Construction

Rocker arms transfer valve train motion to the valve stem tips. In OHC engines, the camshaft may act directly on the rocker arm. Then, the rocker acts on the valve. Some rocker arms are forked so that they can actuate two valves at once. In a push rod engine, the push rod acts on the rocker. Then, the rocker transfers the motion to the valve. See **Figure 13-28.** Rocker arms are usually made of either cast iron or steel.

Various methods are used to support the rocker arms on the cylinder head. Individual ***pivot balls*** or ***stands*** can be used to hold the rocker arm in place over the valve. **Figure 13-29** shows one such arrangement.

Adjustable rocker arms are used to change the valve train clearance. Either a screw is provided on the rocker arm or the rocker arm pivot point can be changed. Adjustable rocker arms *must* be used with mechanical

lifters. ***Nonadjustable rocker arms*** have no means of changing the valve clearance. They are used only with some hydraulic lifters. The rocker arm assembly is tightened to a specific torque. This presets the lifter plunger halfway in its travel. Then, during engine operation, the hydraulic lifter automatically maintains zero clearance. Push rod length can be changed for clearance adjustments when using nonadjustable rocker arms.

Intake Manifold Construction

An ***intake manifold*** holds the throttle body and has passages, called runners, going to each cylinder head port. The manifold usually contains water jackets for cooling. It can be cast of iron, aluminum, or plastic.

Manifold runners are internal passages formed in the intake manifold to carry either the air-fuel mixture or air to the cylinder head ports. **Figure 13-30** is a cutaway of an intake manifold. Notice the exhaust passage, which warms the manifold. Also see **Figure 13-31.**

Manifold adapters

Figure 13-31. A multi-piece "ram manifold" assembly takes the place of a traditional intake manifold on some high-performance engines. Individual tubes supply air to each cylinder. (Cadillac)

Intake manifolds can also be made of glass-filled nylon or plastic. These can weigh half as much as aluminum and several times less than iron. The inside of the plastic runners is also smoother than metal to improve airflow into the engine for more power. With plastic manifolds, brass thread inserts are pressed into the plastic. This allows additional parts, such as sensors and vacuum fittings, to be bolted to the plastic part without thread damage.

Compression limiters are metal inserts that limit the deformation around bolt holes in plastic parts. They allow enough bolt torque to provide good sealing without cracking or deforming the soft plastic.

A ***flame arrester*** is sometimes located before the engine intake manifold to prevent backfire damage to the air filter. It is made of metal mesh to prevent the flame of an engine backfire from entering the air filter housing. It should periodically be removed and cleaned in solvent for best engine performance.

Variable Induction System

A ***variable induction system*** has two sets of intake runners controlled by butterfly valves to aid engine efficiency and performance. At low engine speeds, the system uses the longer intake runners to "ram" more air and fuel into the cylinders for increased torque. Then, when a specific engine speed is reached, the computer opens the butterfly valves over the shorter intake runners. The short runners increase airflow at high rpm for added power.

A variable induction system is like having two intake manifolds in one. One manifold is for low-speed torque and the other is for high-speed power.

Exhaust Manifold Construction

An ***exhaust manifold*** routes burned exhaust gases from the cylinder head exhaust port to the exhaust pipe. Because of the high operating temperatures, the exhaust manifold is usually made of cast iron.

A few high-performance or sports car engines use lightweight, free-flowing steel tubing exhaust manifolds called ***headers.*** **Figure 13-32** shows both intake and exhaust manifolds for one particular engine.

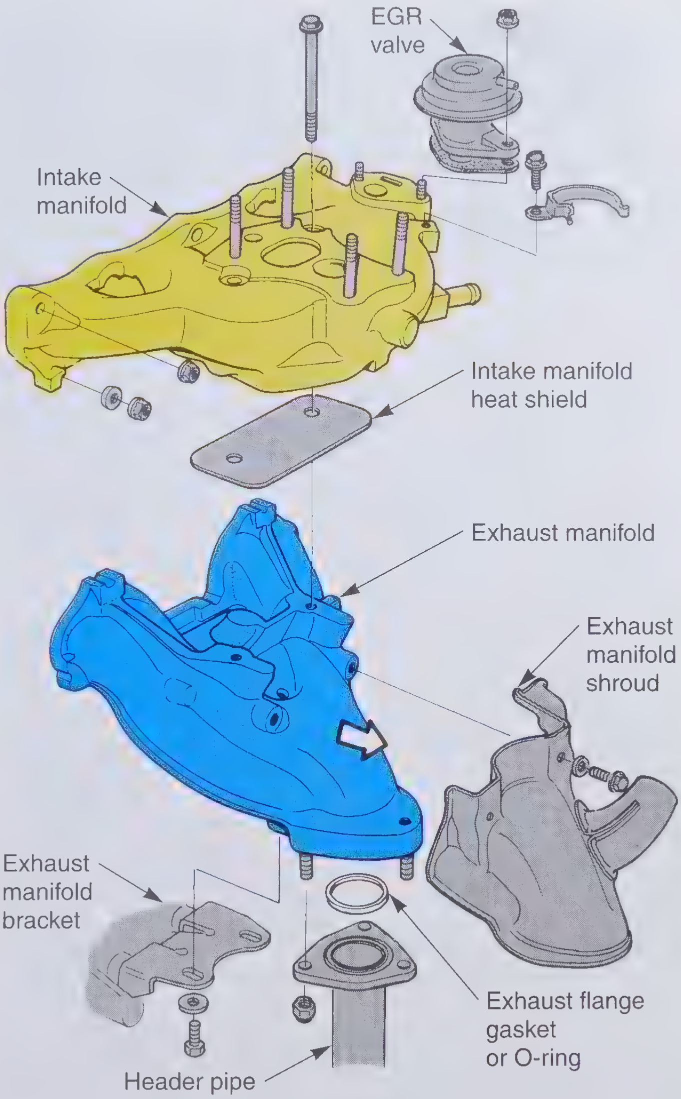

Figure 13-32. Intake and exhaust manifolds shown with their related components. (Honda)

Workplace Skills

A man was driving down the highway one day when the engine temperature light started glowing. Unfortunately, he was late for a meeting and did not think it would hurt anything to drive the car several more miles to the destination.

After a few miles, the engine started making a pinging noise. This was due to excessive combustion chamber temperatures igniting the fuel mixture too early. Unfortunately, the driver kept going. When the car was stopped and the engine shut off, steam was blowing out of the radiator cap. The driver thought he was lucky that the car made it all the way.

The next day, the driver added coolant and started the engine. It missed badly and white smoke blew out of the tailpipe. The car was taken to a repair shop. Engine tests found coolant in the cylinders and exhaust gases in the radiator. After engine disassembly, it was apparent that the aluminum head was warped and cracked from engine overheating. The customer got a quote on engine repairs that was equal to about half the value of his used car.

Today's thin cast aluminum heads are less tolerant of overheating than older, thicker cast iron heads. If you experience engine overheating, do not keep driving the vehicle. Shut the engine off as soon as possible and allow it to cool. Repair the causes of the overheating problem right away.

Summary

- An engine top end basically includes the cylinder head, valve train, valve cover, and the intake and exhaust manifolds.
- A bare cylinder head is a head with all of its parts removed.
- An integral valve guide is part of the cylinder head casting. A pressed-in valve guide is a separate sleeve forced into a hole machined in the head.
- The valve seat angle is the angle formed by the face of the seat.
- An interference angle is a 1/2° to 1° difference between the valve seat face angle and the angle of the valve face.
- The valve face angle is the angle formed between the valve face and valve head.
- An umbrella valve seal is shaped like a cup and can be made of neoprene rubber or plastic.
- An O-ring valve seal is a small round seal that fits into an extra groove cut in the valve stem.
- Spring tension refers to the stiffness of a valve spring.
- A valve spring shim is a very thin and accurately machined washer used to increase spring tension.
- Valve retainers and keepers lock the valve spring on the valve.
- A valve rotator turns the valve to prevent carbon buildup and hot spots on the valve face.
- With dual overhead cam engines, there are two camshafts—the intake camshaft and the exhaust camshaft. The intake camshaft operates all the intake valves in the cylinder head. The exhaust camshaft operates all the exhaust valves.
- Camshaft lift is the amount of valve lift produced by the cam lobe.
- Camshaft duration determines how long the valve stays open.
- Valve timing refers to valve opening and closing in relation to the position of the pistons in the cylinders.
- Valve overlap is the time when both of the intake and exhaust valves in the same cylinder are open.
- Valve lifters, or tappets, ride on the camshaft lobes and transfer motion to the other parts of the valve train.
- Push rods are metal tubes with specially formed ends.
- Rocker arms transfer valve train motion to the valve stem tips.

Review Questions—Chapter 13

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What is a bare cylinder head?
2. A(n) _____ type valve guide is part of the cylinder head.

3. A(n) _____ valve guide is a separate sleeve forced into a hole in the cylinder head.
4. Cylinder heads use _____ or _____ valve seats.
5. What is the function of an interference angle on the valve face and seat?
6. This part is pressed into the cylinder head on most automotive diesel engines.
   (A) Stratified charge chamber.
   (B) Glow plug.
   (C) Injector nozzle.
   (D) Prechamber cup.
7. Engines use poppet valves, which are also called _____ valves.
8. Define the term "valve face angle."
9. Why are some valves filled with sodium?
10. Stellite valves are used in engines designed to burn _____ _____.
11. Describe the two basic types of valve seals.
12. Which of the following does *not* pertain to valve springs?
    (A) Free length.
    (B) Tension.
    (C) Tensile strength.
    (D) Closed length.
13. What is the function of a valve spring shim?
14. What is used to lock the valve spring on the valve?
15. A(n) _____ _____ can be used to turn the valve and prevent hot spots on the valve face.
16. Variations in camshaft lobe shape control:
    (A) when each valve opens.
    (B) how long each valve stays open.
    (C) how far or wide each valve opens.
    (D) All of the above.
17. Explain the following terms: Camshaft lift, Camshaft duration, Valve timing, Valve overlap.
18. Why are hydraulic valve lifters used more than solid or mechanical lifters?
19. _____ lifters reduce friction and are frequently used in diesel or high-performance applications.
20. The cam base circle diameter of a camshaft is 3/4″. The camshaft's cam lobe height is 1 1/2″. What is the approximate camshaft lift of this engine?
    (A) 3/8″.
    (B) 1/4″.
    (C) 1/2″.
    (D) None of the above.

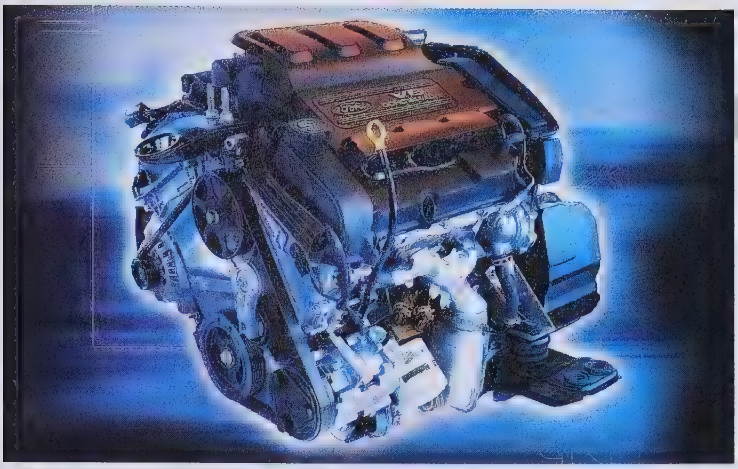
ASE-Type Questions

1. An engine top end typically consists of each of these *except:*
   (A) valve train.
   (B) connecting rod.
   (C) cylinder head.
   (D) intake manifold.
2. Which of the following is a hole machined through the cylinder head?
   (A) Stellite face.
   (B) Valve seat insert.
   (C) Integral valve guide.
   (D) Pressed-in valve guide.
3. Common passenger car engines have a valve seat angle of:
   (A) 10°.
   (B) 20°.
   (C) 25°.
   (D) 45°.
4. Which of the following is a cross between an oil seal and a valve spring shield?
   (A) Nylon shedder.
   (B) O-ring valve seal.
   (C) Valve spring shim.
   (D) Umbrella valve seal.
5. Low valve spring tension can cause:
   (A) valve float.
   (B) valve rotation.
   (C) valve spring shim.
   (D) mushroomed valves.
6. Which of the following is used to lock a valve spring on a valve?
   (A) Retainer.
   (B) Keeper.
   (C) Seal.
   (D) Both A and B.
7. Which of the following is *not* a method by which a camshaft can be driven?
   (A) Belt.
   (B) Chain.
   (C) Gears.
   (D) Rotator.
8. A cam lobe consists of each of these *except:*
   (A) heel.
   (B) nose.
   (C) head.
   (D) flank.

9. The device used to limit camshaft end-play is the:
   - (A) *cam cover.*
   - (B) *thrust plate.*
   - (C) *cam bearings.*
   - (D) *valve overlap.*
10. Which type of valve lifter is filled with oil?
    - (A) *Solid.*
    - (B) *Hydraulic.*
    - (C) *Mechanical.*
    - (D) *All of the above.*

Activities for Chapter 13

1. The rocker arm is a form of lever. Do research to find out what class of lever it is. Construct simple models of the three classes of levers and describe for the class how they work.
2. Make a sketch of a cam lobe, like the one shown in **Figure 13-18.** Assume that TDC is 0°. Use a protractor to mark points for a 90°, 180°, and 270° rotation. Using pencils or pens of different colors, draw the cam lobe in each of these positions.
3. If a disassembled engine is available, examine the head to determine whether integral or pressed-in valve guides and valve seats are used.



14

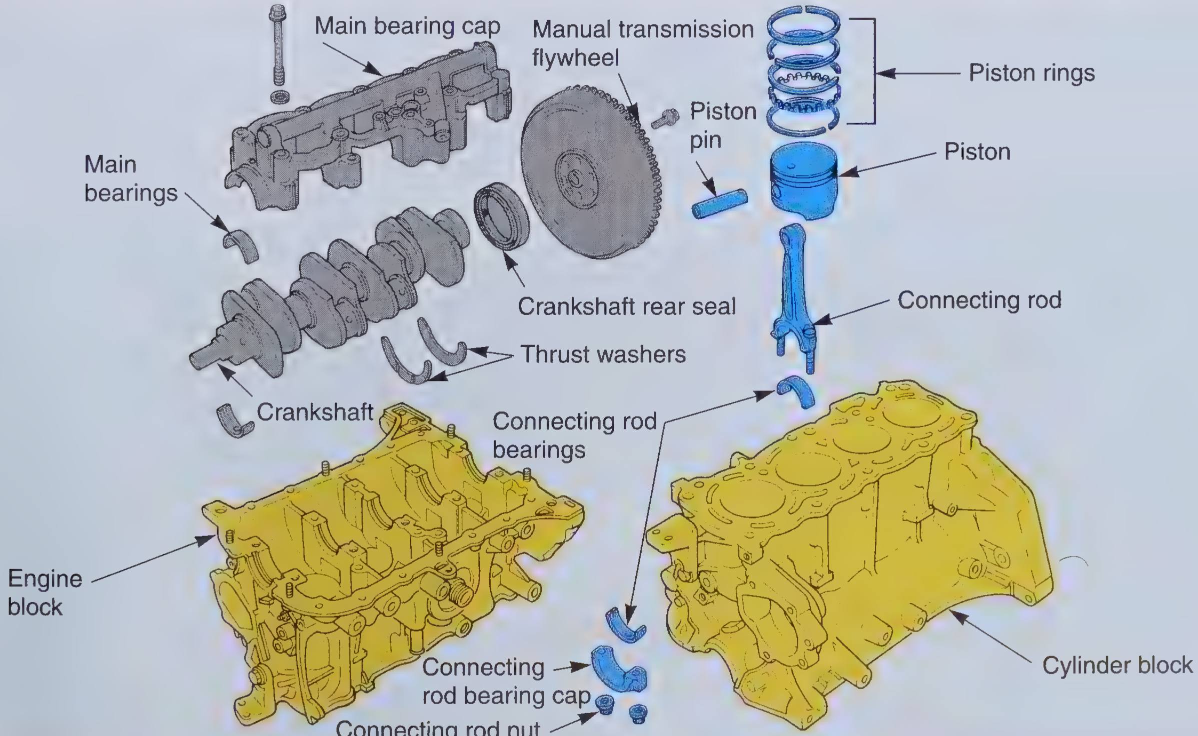
Engine Bottom End Construction

After studying this chapter, you will be able to:

- Compare the construction of different types of cylinder blocks.
- Explain how piston construction affects engine operation.
- Describe piston ring variations.
- Explain the construction of engine bearings.
- Compare design variations of different engine bottom end components.
- Explain safe practices when working with engine bottom end components.
- Correctly answer ASE certification test questions on engine bottom end construction.

The basic parts of an ***engine bottom end*** are the block, crankshaft, connecting rods, bearings, and piston assemblies. These components are shown in **Figure 14-1.**

This chapter details construction techniques commonly used in an engine bottom end assembly. This information will help you understand how to repair engine bottom end components.



Main bearing cap
Manual transmission flywheel
Piston rings
Piston pin
Piston
Main bearings
Crankshaft rear seal
Connecting rod
Thrust washers
Crankshaft
Connecting rod bearings
Engine block
Connecting rod bearing cap
Cylinder block
Connecting rod nut

Figure 14-1. The engine bottom end assembly consists of the block, crank, rods, pistons, and rings. Understanding the construction of these components is very important to service and repair operations. (Honda)

Cylinder Block Construction

Engine cylinder blocks are normally made of cast iron or aluminum, **Figure 14-2.** A ***cast iron cylinder block*** is very heavy and strong. Nickel is sometimes added to the iron to improve strength and wear resistance. An ***aluminum cylinder block*** is relatively light. An aluminum block also dissipates heat better than a cast iron block. Many late-model vehicles use aluminum blocks to reduce weight and increase fuel economy.

Cylinder Sleeves

Cylinder sleeves, or ***liners,*** are metal, pipe-shaped inserts that fit into the cylinder block. They act as cylinder walls for the piston to slide up-and-down on, **Figure 14-2.**

Cast iron sleeves are commonly used in aluminum cylinder blocks. Sleeves can also be installed to repair badly damaged cylinder walls in cast iron blocks. There are two basic types of cylinder sleeves—dry sleeves and wet sleeves. These are shown in **Figure 14-3.**

A ***dry sleeve*** presses into a cylinder that has been bored, or machined, oversize. Look at **Figure 14-4A.** A dry sleeve is relatively thin and is not exposed to engine coolant. The outside of a dry sleeve touches the walls of the cylinder block. This provides support for the sleeve.

When a cylinder becomes badly worn or is damaged, a dry sleeve can be installed. The original cylinder must be bored almost as large as the outside diameter of the sleeve. Then, the sleeve is pressed into the oversized hole. Next, the inside of the sleeve is machined to the original bore diameter. This allows the use of the original piston size.

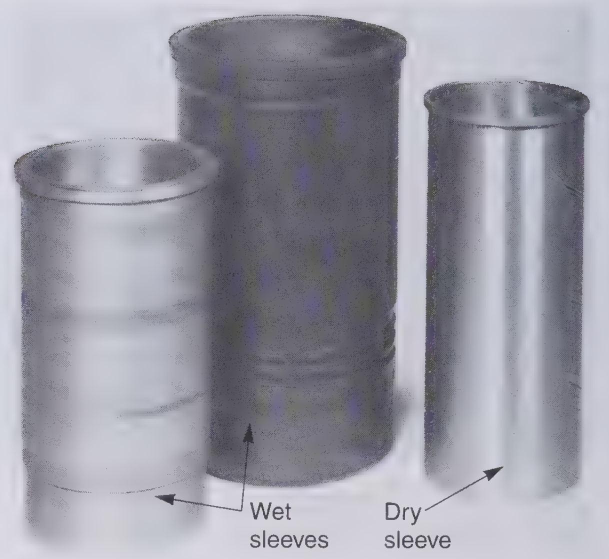


Figure 14-3. Notice the difference between the two wet sleeves and the one dry sleeve. (Dana Corp.)

A ***wet sleeve*** is exposed to the engine coolant. It must withstand combustion pressure and heat without the added support of the cylinder block. Therefore, it must be thicker than a dry sleeve. Refer to **Figure 14-4B.**

A wet sleeve will generally have a flange at the top. When the head is installed, the clamping action pushes down on the sleeve and holds it in position. The cylinder head gasket keeps the top of the sleeve from leaking. A rubber or copper O-ring is used at the bottom of a wet sleeve to prevent coolant leakage into the crankcase. The O-ring seal is pinched between the block and the sleeve to form a leakproof joint.

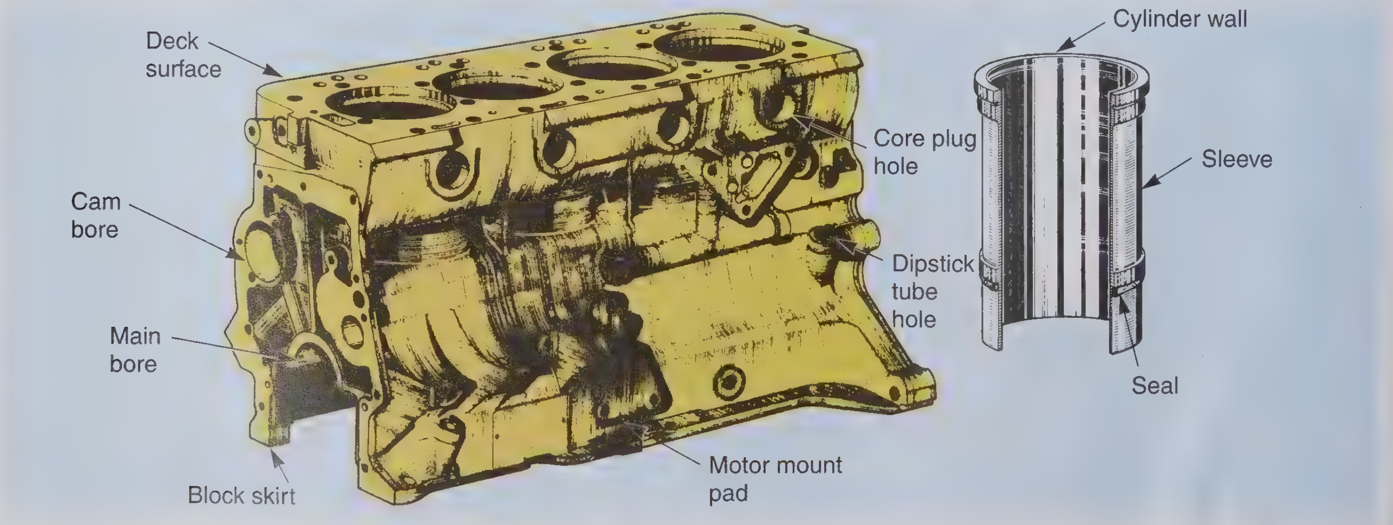

Figure 14-2. A cylinder block may be cast from iron or aluminum. The cylinder may be an integral part of the block or formed by a pressed-in liner.

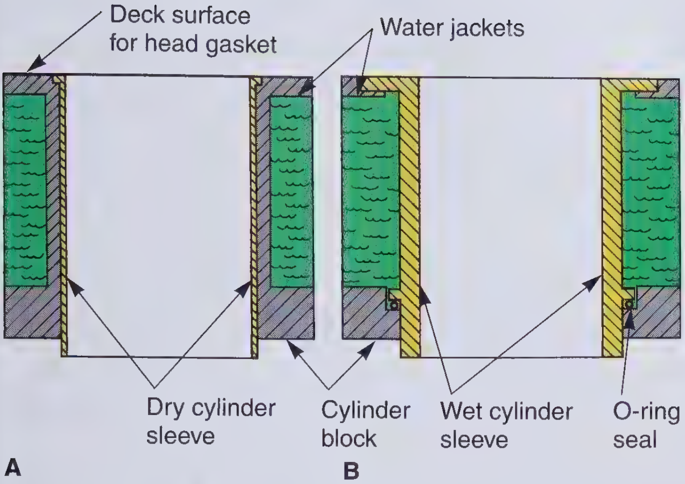

Figure 14-4. A—A dry sleeve presses into existing cylinder bore. It is not exposed to engine coolant. B—A wet sleeve is thicker to withstand combustion pressure and heat. It is also exposed to coolant.

Many vehicles use aluminum cylinder blocks with cast iron, wet sleeves. The light aluminum block reduces weight for increased fuel economy. The cast iron sleeves wear very well, increasing engine service life. Refer to **Figure 14-5.**

Line Boring

The term ***line boring*** refers to a machining operation that cuts a series of holes through the block for the crankshaft bearings. A block may also be line bored for the camshaft bearings. The holes must be in perfect alignment for the crankshaft or camshaft to turn freely. Line boring can also be done to an OHC cylinder head.

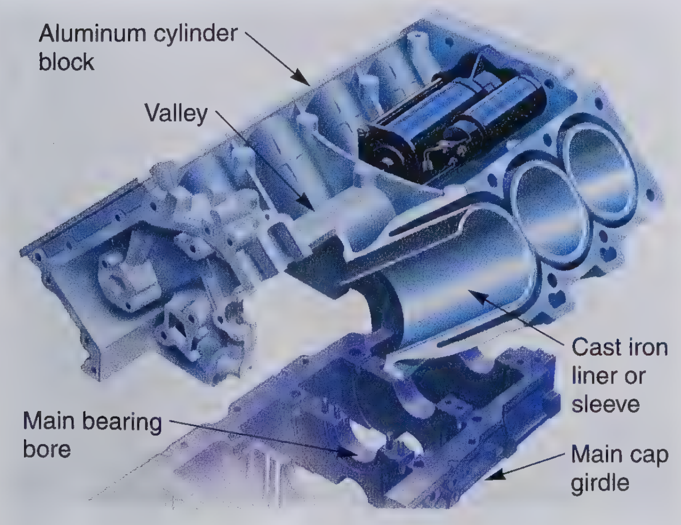

Figure 14-5. Modern cylinder blocks are frequently made of aluminum with pressed-in, cast iron wet sleeves. (Cadillac)

Two- and Four-Bolt Mains

A ***two-bolt main block*** only uses two cap screws to secure each main bearing cap to the cylinder block. A ***four-bolt main block*** has four cap screws holding each main cap. Four-bolt mains are used on high-performance engines. A few engines use six-bolt main caps. With extra bolts, the block can withstand more crankshaft downward pressure without part failure.

Crossbolted Block

A ***crossbolted block*** has extra cap screws going in through the sides of the block and main caps for added strength. This design is often used on high-performance engines.

Block Girdle

A ***block girdle,*** or ***main bearing bedplate,*** is a large one-piece cap that fits over the entire bottom of the block. Also called a ***unit main cap,*** it secures the main bearings. All the main caps are formed as one piece to increase strength and block stiffness. The bedplate can also hold any balancer shafts. Gears on the crankshaft are used to drive the balancer shafts.

Piston Construction

Engine pistons are normally cast or forged from an aluminum alloy. Cast pistons are relatively soft and are used in slow-speed, low-performance engines. Forged pistons are commonly used in today's fuel-injected, turbocharged, and diesel engines. These engines expose the pistons to much higher stress loads, which could break cast aluminum pistons.

Since aluminum is very light and relatively strong, it is an excellent material for engine pistons. When an engine is running at highway speeds, the piston must withstand tremendous loads. A piston may accelerate from zero to 60 mph and then back to zero, all in about four inches of piston travel. A heavy piston could break the connecting rod. A weak piston could fall apart under these loads.

The design of a piston must provide maximum strength and minimum weight. **Figure 14-6** shows a cutaway view of an engine piston. Notice how the piston is thicker at stress points. The top of the piston is exposed to combustion and tremendous heat. It can reach operating temperatures as high as 650°F (345°C). Several design methods are used to provide dependable, quiet piston operation.

Oil groove
Skirt
Pin boss

Figure 14-6. Piston construction is critical because of extreme loads. This piston is for a diesel engine and has a groove that allows an oil spray to help cool the piston. Diesel pistons must be made much thicker and heavier than pistons for gasoline engines. Pressure and temperatures in a diesel are higher. (DaimlerChrysler)

Piston Dimensions

Figure 14-7 illustrates several piston dimensions. These dimensions affect how the piston functions in the cylinder. These dimensions are explained as follows.

- ***Piston diameter***—the distance measured across the sides of the piston.
- ***Pin hole diameter***—the distance measured across the inside of the piston pin hole.
- ***Ring groove width***—the distance measured from the top to the bottom of the ring groove.
- ***Ring groove depth***—the distance measured from the ring land to the back of the ring groove.
- ***Skirt length***—the distance from the bottom of the skirt to the centerline of the pin hole.
- ***Compression distance***—the distance from the centerline of the pin hole to the top of the piston.

Figure 14-7. The basic dimensions of a piston.

Cam-Ground Piston

A ***cam-ground piston*** is slightly out of round when viewed from the top. The piston is machined a few thousandths of an inch larger in diameter perpendicular to the piston pin centerline. See **Figure 14-8.**

Cam grinding is done to compensate for different rates of piston expansion due to differences in metal wall thickness. As the piston is heated by combustion, the thicker area around the pin boss causes the piston to expand more parallel to the piston pin. The oval-shaped piston becomes round when hot, and there is still enough clearance parallel to the piston pin.

A cold cam-ground piston has the correct piston-to-cylinder clearance. The unexpanded piston will *not* slap, flop sideways, and knock in the cylinder because of too much clearance. However, the cam-ground piston will

not become too tight in the cylinder when heated to full operating temperature.

Piston Taper

Piston taper is also used to maintain the correct piston-to-cylinder clearance. The top of the piston is machined slightly smaller than the bottom, **Figure 14-9.** Since the piston head gets hotter than the skirt, it expands more. The piston taper makes the piston almost equal in size at the top and bottom at operating temperature.

Piston Shape

Piston shape generally refers to the contour of the piston head. Usually, a piston head is shaped to match and work with the shape of the cylinder head combustion chamber. See **Figure 14-10.** The head of a ***flat top piston*** is almost flat and is parallel with the block's deck surface. Refer to **Figure 14-11.** A flat top piston is commonly used with a wedge- or pancake-type cylinder head.

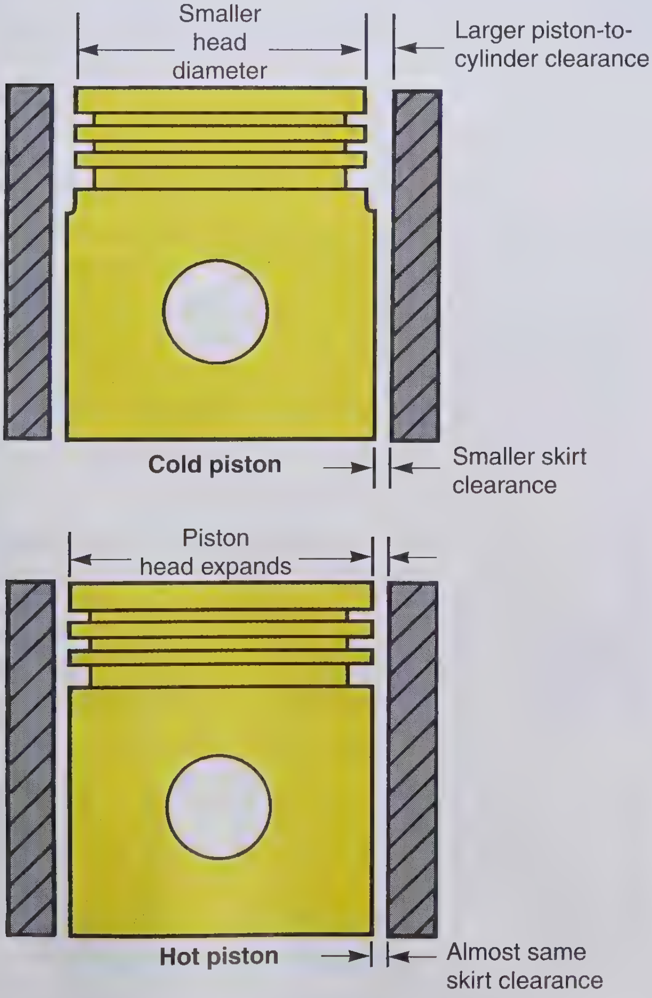

Figure 14-9. Piston taper compensates for more expansion around the piston head. The head becomes hotter than the skirt and expands more. By machining the head smaller, the piston diameter becomes almost equal at the top and bottom when hot.

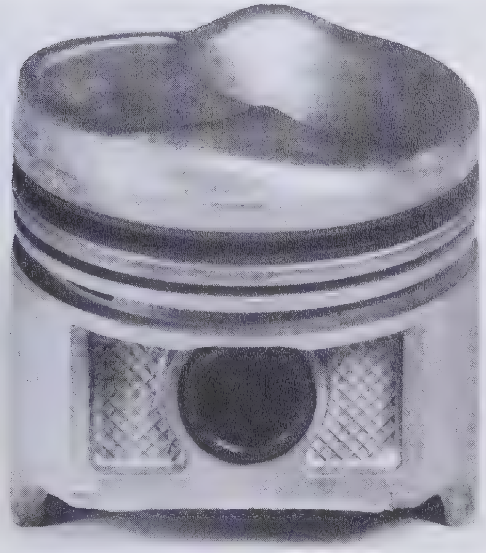

Figure 14-10. A piston's head shape is designed to work with the shape of the cylinder head combustion chamber. This is a piston for a diesel engine having a direct injection nozzle. (Dana Corp.)

A ***domed,*** or ***pop-up, piston*** has a head that is convex, or curved upward. This type is normally used with a hemi-type cylinder head and some four-valve heads. The piston crown must be enlarged to fill the domed combustion chamber and produce enough compression pressure.

A ***dished piston*** has a head that is sunken, or recessed. This type of piston can be used to lower compression pressure in a turbocharged or supercharged engine. Some diesel engines have a domed and dished piston to work with direct fuel injection.

A ***flat-top piston***, as its name implies, has a flat head. Valve reliefs are cut into the head of this type of piston. Flat-top pistons are often used with wedge-type cylinder heads.

Valve reliefs are small indentations either cast or machined into the piston crown to provide ample piston-to-valve clearance. Without valve reliefs, the valve heads could strike the pistons. Valve reliefs are shown in **Figure 14-11.**

Slipper Skirt

A ***slipper skirt*** is produced when the portions of the piston skirt below the piston pin ends are removed, as in **Figure 14-11.** A slipper skirt provides clearance between the piston and the crankshaft counterweights. The piston can slide farther down in the cylinder without hitting the crankshaft.

Variable Compression Piston

A ***variable compression piston*** is a two-piece design controlled by engine oil pressure. The head of the piston fits over and slides on the main body of the piston. Engine oil pressure is fed between the two halves to form a hydraulic cushion. With normal driving, the oil pressure extends the top of the piston out for maximum compression ratio and power. When engine speed increases, the added combustion pressure pushes the head of the piston down to lower the compression ratio. This prevents engine knocking or pinging.

Piston Ring Construction

Automotive pistons normally use three rings—two compression rings and one oil ring. Refer to **Figure 14-11.** It is important for you to understand how variations in ring construction provide different operating characteristics.

The ***compression rings*** prevent pressure leakage into the crankcase. They also wipe some of the oil from the cylinder walls. To accomplish these functions, ring shapes vary, as shown in **Figure 14-12.** These shapes help the ring seal and remove oil from the cylinder.

Compression rings are usually made of cast iron. An outer layer of chrome or other metal may be used to increase wear resistance. The face of compression rings may also be grooved to speed ring seating. ***Ring seating*** is the initial ring wear that makes the ring perfectly match surface of cylinder.

Oil rings are available in two basic designs: rail-spacer type and one-piece type, **Figure 14-13.** The

Figure 14-12. Various compression ring shapes are available. Each type is designed to help the ring prevent combustion pressure from leaking into the crankcase. (Ford)

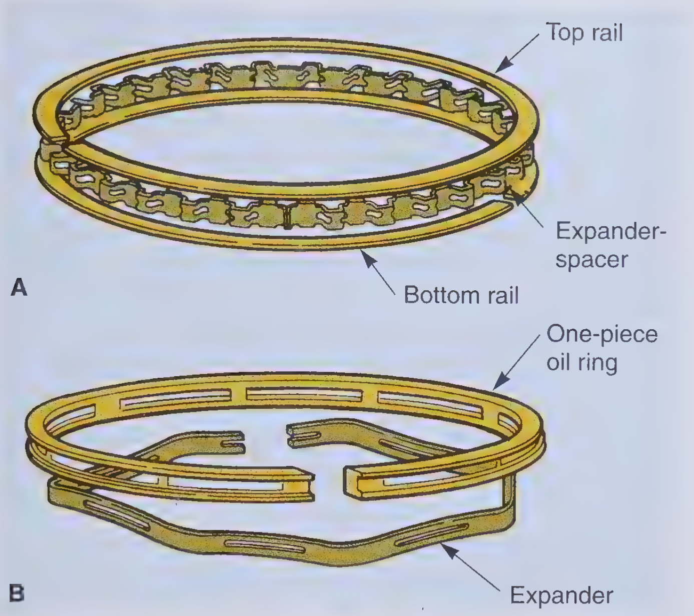

Figure 14-13. An oil ring must wipe excess oil off the cylinder wall. A—A three-piece oil ring is the most common type. B—A one-piece oil ring is made from cast iron. Slots in the ring allow oil to flow through holes in the piston groove and back into the oil pan. (Ford)

primary function of oil rings is to keep crankcase oil out of the combustion chambers. A three-piece oil ring consisting of two rails, or scrapers, and an expander-spacer is the most common. The ***ring expander-spacer*** holds the two steel oil ring rails apart and helps push them outward, **Figure 14-13A.** A ***ring expander*** can be placed behind a one-piece oil ring to increase ring tension, **Figure 14-13B.** It can also be used behind the second compression ring. The expander helps push the ring out against the cylinder wall, increasing the ring's sealing action.

Piston Ring Dimensions

Basic piston ring dimensions include the width, radial wall thickness, and gap. Refer to **Figure 14-14.** These dimensions affect the operation of the engine. Ring side and back clearances are also very important. They must be within factory specifications or poor engine performance could result.

The ***piston ring width*** is the distance from the top of the ring to the bottom of the ring. The difference between the ring width and the width of the piston ring groove determines the ***ring side clearance.***

The ***piston ring radial wall thickness*** is the distance from the face of the ring to its inner wall. The difference between the ring wall thickness and ring groove depth determines the ***ring back clearance.***

The ***piston ring gap*** is the distance between the ends of the ring when installed in the cylinder. This is pictured in **Figure 14-15.** The ring gap allows the ring to be installed on the piston and to "spring outward" in its cylinder. The gap also allows the ring to conform to any variation in the cylinder diameter due to wear.

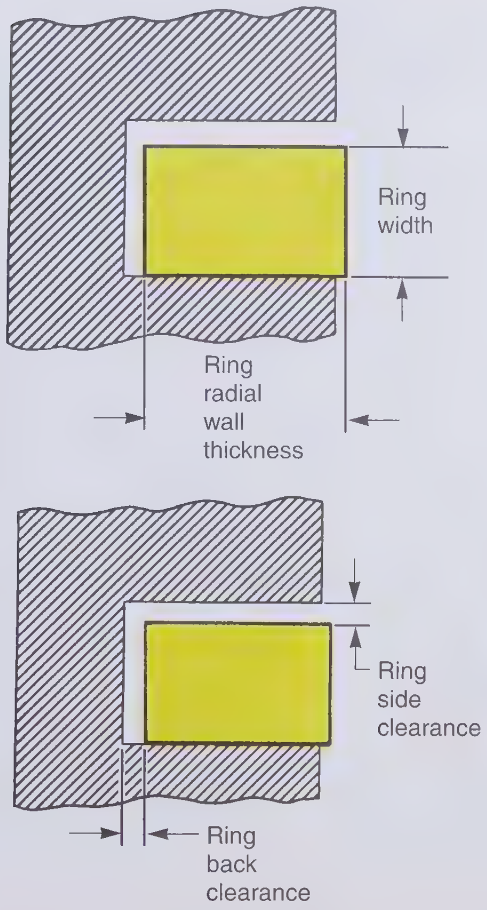

Figure 14-14. Ring width, ring groove depth, ring radial wall thickness, and ring groove height determine the ring back and side clearances. (Perfect Circle)

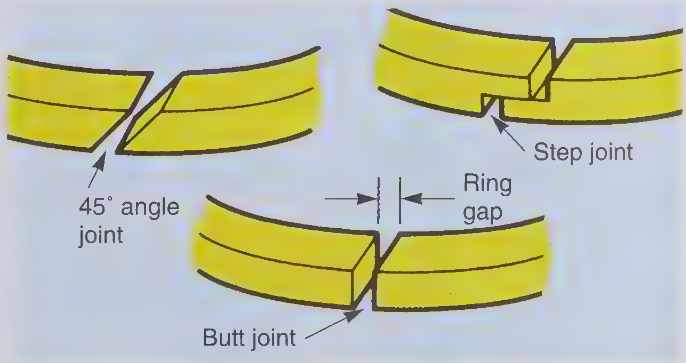

Figure 14-15. The ring gap is the small space between the ends of the ring when it is installed on the piston and the piston is in the cylinder. Most modern piston rings use a butt joint. (Ford)

Piston Ring Coatings

Soft ring coatings of porous metal, usually iron, help the ring wear in quickly, forming a good seal. The soft outer surface will wear away rapidly so the ring conforms to the shape of the cylinder. Rings with these coatings, often called ***quick seal rings,*** are commonly recommended for used cylinders that are slightly worn.

Hard ring coatings, such as chrome or moly, are used to increase ring life and reduce friction. Rings with these coatings are used in new or freshly machined cylinders that are perfectly round and *not* worn. To aid break-in, chrome-plated rings usually have ribbed faces. The ribs hold oil and wear quickly to produce a good seal.

Tech Tip!

Avoid using rings with hard coatings when rebuilding a passenger car engine. The hard rings are more difficult to seat than softer rings. Soft rings are more forgiving of cylinder wall imperfections. Engine smoking problems are more common in rebuilt engines when hard rings are used, because the rings take much longer to seat.

Piston Pin Construction

Piston pins are normally made of case-hardened steel. ***Case-hardening*** is a heating and cooling process that increases the wear resistance of the piston pin. It hardens the outer layer of metal on the pin. The inner metal remains unhardened so the pin is not too brittle. The hollow piston pin is also machined and polished to a very precise finish. Piston pins are held in the piston by one of two means—snap rings or a press-fit.

A ***full-floating piston pin*** is secured by snap rings and is free to rotate in both the rod and piston. Look at **Figure 14-16A.** The pin is free to "float" in both the piston pin bore and the connecting rod small end.

Full-floating piston pins are better than press-fit pins because they reduce friction and wear. A bronze bushing is usually used in the connecting rod. The piston pin hole serves as the other bearing surface for the pin. The snap rings fit into grooves machined inside the piston pin hole.

A ***press-fit piston pin*** is forced tightly into the connecting rod's small end. It can rotate freely in the piston pin hole. However, the pin is *not* free to move in the connecting rod, **Figure 14-16B.** This holds the pin inside the piston and prevents it from sliding out and rubbing on the cylinder wall. The press-fit is a very dependable piston pin design. It is also inexpensive to manufacture.

Piston Pin Offset

A ***piston pin offset*** locates the piston pin hole slightly to one side of the piston centerline. This helps quiet the piston during use. The pin hole is moved toward the piston's major thrust surface. This is the surface of the

piston that is pushed tightly against the cylinder wall during the power stroke.

If the pin hole were centered in the piston, the piston could slap or knock in the cylinder. As the piston moves up in the cylinder, it could be positioned opposite the major thrust surface. Then, during combustion, the piston could be rapidly pushed to the opposite side of the cylinder, producing a knocking sound. With the pin offset, the piston tends to be pushed against its major thrust surface. This reduces its tendency to slap sideways in the cylinder.

A ***piston notch*** or other marking on the head of the piston is frequently used to indicate piston pin offset and the front of the piston. Look at **Figure 14-17.** The piston may also have the word "front" or an arrow stamped on it. This information lets you know how to position the piston in the block for correct location of the piston pin offset.

Connecting Rod Construction

Most connecting rods are made of steel. The rod must withstand tons of force as the piston moves up and down in the cylinder. Connecting rods normally have an I-beam shape. This shape has a high strength-to-weight ratio.

Connecting rods must be very strong, but as light as possible for low inertia forces from their changes in direction at top dead center (TDC) and bottom dead center (BDC). ***Low-inertia parts*** are light parts that will accelerate quickly.

Some connecting rods have an ***oil spurt hole*** that provides added lubrication for the cylinder walls, piston pin, and other surrounding parts. See **Figure 14-19.** Oil pressure forces oil out when the holes in the crankshaft journal and bearing align with the spurt hole. A ***drilled connecting rod*** has a machined hole through its entire length. The purpose of this hole is to supply oil to the piston pin.

Connecting rod numbers are used to ensure proper location of each connecting rod in the engine. They also

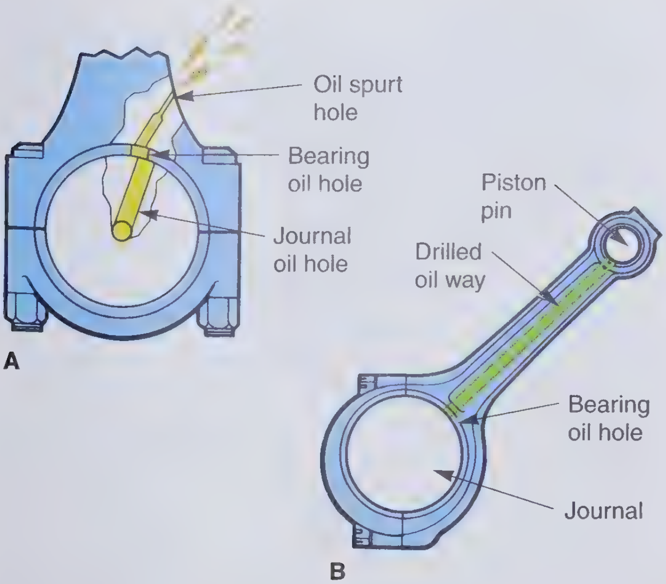

Figure 14-19. A—Oil spurt holes provide added lubrication for the piston pin, cam lobes, cylinder walls, and other surrounding parts. B—A drilled rod allows oil to enter the clearance between the pin and bushing. (Federal Mogul)

ensure that the rod cap is installed on the rod body correctly. Look at **Figure 14-20.**

During manufacture, connecting rod caps are bolted to the connecting rods. Then, the crank holes are machined in the rods. Since these holes may not be perfectly centered, rod caps must *not* be mixed up or turned around. If the cap is installed without the rod numbers in alignment, the bore will *not* be perfectly round. Severe rod, crankshaft, and bearing damage will result.

A ***broken-surface rod*** is scribed and broken off when manufactured to produce a rough, irregular mating surface between the rod body and cap. This is done to help lock the rod and cap into alignment. The broken, irregular surfaces match perfectly to prevent the rod and cap from shifting during engine operation. This type of rod cannot be rebuilt. However, oversize rod bearings can still be installed during an engine rebuild.

Powdered metal forging refers to a process that forms the rough shape of the part out of metal powder before final shaping in a powerful forge. Some connecting rods are powerded metal forged to help control the shape and weight while reducing machining.

Machined block forging involves initial turning in a lathe to bring the blank of metal to size before forming it in a drop or press forge. This process helps eliminate flashing. ***Flashing*** is the small lip of rough metal produced when the two halves of the forge come together to "smash" the metal into shape. By reducing flashing, a step is removed from the manufacturing process.

Crankshaft Construction

Engine crankshafts are usually made of cast iron or forged steel. Forged steel crankshafts are needed for heavy-duty applications, such as turbocharged or diesel engines. A steel crankshaft is stiffer and stronger than a cast iron crankshaft. It will withstand greater forces without flexing, twisting, or breaking.

Oil passages leading to the rod and main bearings are either cast or drilled in the crankshaft, **Figure 14-21.** Oil enters the crankshaft at the main bearings and passes through holes in the main bearing journals. It then flows through passages in the crankshaft and out to the connecting rod bearings.

With an inline engine, only *one* connecting rod fastens to each rod journal. With a V-type engine, *two* connecting rods bolt to each rod journal. The amount of rod journal offset controls the stroke of the piston. The journal surfaces are precision machined and polished to very accurate tolerances. It is common to have reduced

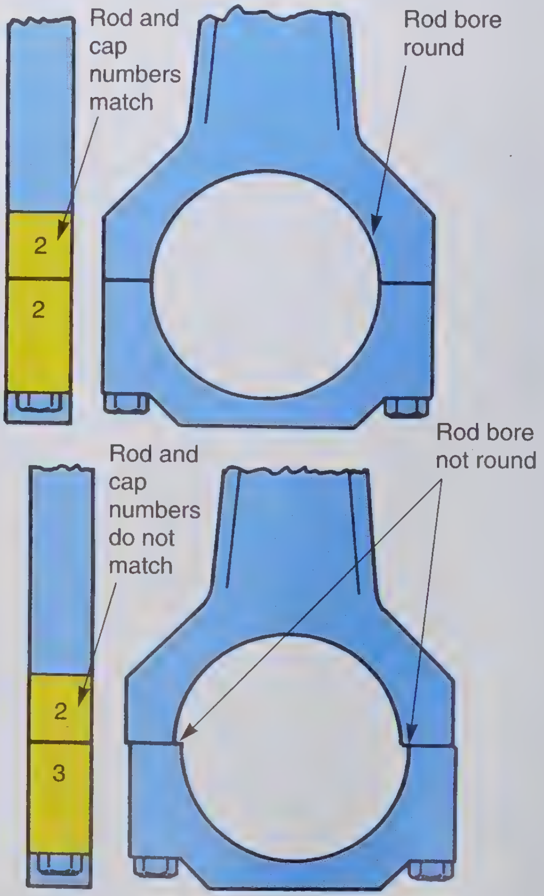

Figure 14-20. A rod cap must be installed on the rod correctly. If rod caps are mixed up or turned, the bore for the bearing may not be round. The bearing could be crushed into the crankshaft journal, damaging both.

journal, or ***crankpin,*** diameters in order to reduce friction in the bearings.

A ***fully counterweighted crankshaft*** has weights formed opposite every crankpin. A ***partially counterweighted crankshaft*** only has weights formed on the center areas. A fully counterweighted crankshaft will operate with less vibration than a partially counterweighted crankshaft.

Engine Bearing Construction

There are three basic types of engine bearings: connecting rod bearings, crankshaft main bearings, and camshaft bearings. This is illustrated in **Figure 14-22.**

Steel is normally used for the bearing body, or backing, which contacts the stationary part of the engine. Softer alloys are bonded over this backing to form the bearing surface.

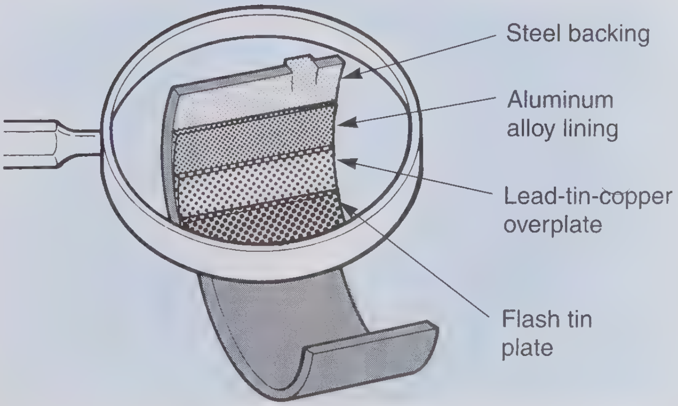
Any one of three metal alloys can be plated over the steel backing. These are ***babbitt*** (a lead-tin alloy), copper, or aluminum. These three metals may be used in different combinations to design bearings for use in light-, medium-, heavy-, or extra-heavy-duty applications. See **Figure 14-23.**

Bearing Characteristics

Engine bearings must operate under tremendous loads, severe temperature variations, abrasive conditions, and corrosive surroundings. Essential bearing characteristics are described below. It is important to understand each of these.

Bearing load strength is the bearing's ability to withstand pounding and crushing during engine operation. The piston and rod can produce several tons of force. The bearing must not fail under these loads. If bearing load resistance is too low, the bearing can smash, spin, or split. This can ruin the bore or journal.

Bearing conformability is the bearing's ability to adjust to imperfections in the journal surface. Usually, a soft metal is plated over a hard steel backing. This lets the bearing conform to any defects in the journal.



Steel backing
Aluminum alloy lining
Lead-tin-copper overplate
Flash tin plate

Figure 14-23. Typical construction of an engine bearing. Steel backing forms the body of the bearing. Other alloys are plated over the backing to provide better operating characteristics. (Federal Mogul)

Bearing embedability refers to the bearing's ability to absorb dirt, metal, or other hard particles. Dirt or metal is sometimes carried into the bearings. The bearing should allow the particles to sink into the bearing material. This prevents the particles from scratching, wearing, and damaging the surface of the crankshaft or camshaft journal.

Bearing corrosion resistance is the bearing's ability to withstand being acted on by acids, water, and other impurities in the engine oil. Combustion blowby gases cause oil contamination that can also corrode the engine bearings. Aluminum-lead and other alloys are commonly used because of their excellent corrosion resistance.

Bearing Crush

Bearing crush is used to help prevent the bearing from spinning inside its bore during engine operation. Pictured in **Figure 14-24,** the bearing is made slightly larger than the bearing bore. The end of the bearing is slightly above the bore. When the rod or main cap is tightened, the bearing ends press against each other. This jams the back sides of the bearing inserts tightly against the bore, locking them in place.

Bearing Spread

Bearing spread is used on a split-type engine bearing to hold the bearing in place during assembly. The distance across the parting line of the bearing is slightly wider than the bearing bore. This causes the bearing insert to stick in its bore when pushed into place with your fingers. Tension from bearing spread keeps the bearing from falling out of its bore as you assemble the engine.

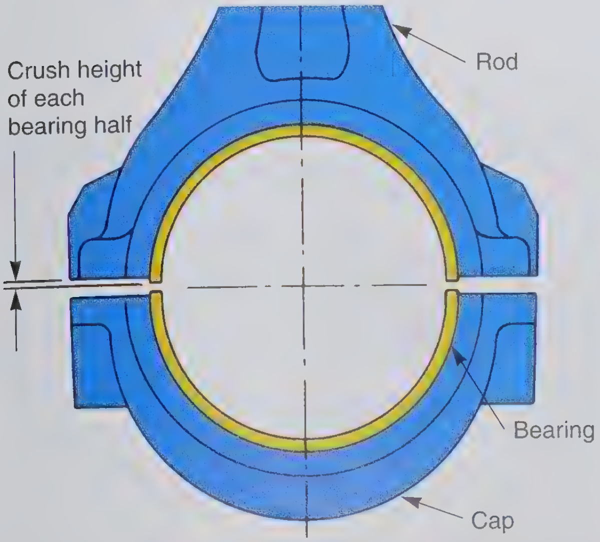


Figure 14-24. Bearing crush is produced when bearings are made slightly larger than the bearing bore. When the cap is bolted down, the bearing is forced into the bore. This keeps the bearing from turning with the crankshaft. (Deere & Co.)

Standard and Undersize Bearings

A ***standard bearing*** has the original dimensions specified by the engine manufacturer for a new, unworn, or unmachined crankshaft. A standard bearing may have the abbreviation "STD" stamped on its back.

An ***undersize bearing*** is designed to be used on a crankshaft journal that has been machined to a smaller diameter. If the crankshaft journals have been worn or damaged, they can be ground undersize by a machine shop. Then, undersize bearings are needed. Connecting rod and main bearings are available in undersizes of 0.010″, 0.020″, 0.030″, and sometimes 0.040″. The undersize is normally stamped on the back of the bearing, as in **Figure 14-25.** The crankshaft may also have an undersize number stamped on it by the machine shop.

Bearing Locating Lugs and Dowels

Bearing locating lugs and ***dowels*** position split bearings in their bores. Look at **Figure 14-26.** The bearing usually has a lug that fits into a recess machined in the bearing bore or cap. Sometimes a dowel in the cap or bore fits in a hole in the bearing insert. Either method helps keep the insert from shifting or turning during crankshaft rotation.

Bearing Oil Holes and Grooves

Bearing oil holes and ***grooves*** in the engine bearings permit bearing lubrication. The holes allow oil to flow

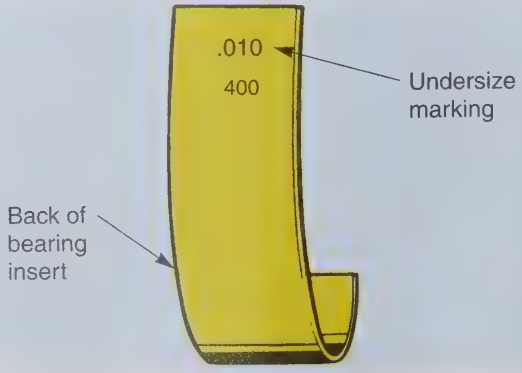

Figure 14-25. The bearing undersize is stamped on the back of the bearing. An undersize marking of 0.010″, for example, means that crankshaft journal has been ground 0.010″ smaller in diameter. Undersize bearings are needed to maintain correct bearing clearance. (Buick)

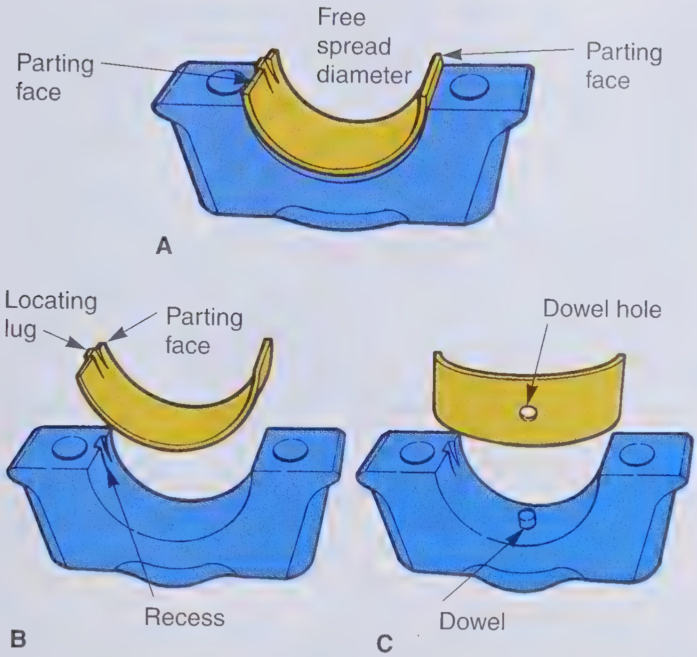

Figure 14-26. Bearing locating lugs or dowels can be used to position engine bearings in their bore. A—Spread. B—Lug. C—Dowel. (Federal Mogul)

through the block and into the clearance between the bearing and the journal. The grooves provide a channel so oil can completely encircle the bearing before flowing over and out of it. See **Figure 14-27.**

Main Thrust Bearings, Thrust Washers

A ***main thrust bearing*** limits crankshaft end play. ***Crankshaft end play*** is the forward and rearward movement of the crankshaft. Thrust flanges are formed on the main bearing sides. These flanges almost touch the thrust surfaces machined on the crankshaft. Shown in **Figure 14-28A,** this keeps the crank from sliding back and forth in the block.

Thrust washers are sometimes used instead of thrust bearings to limit crank end play. The thrust washers are separate parts from the main bearing. They slide down into the space between the crankshaft and block, as pictured in **Figure 14-28B.**

Figure 14-29 shows how a main bearing, thrust washers, main cap, and related components assemble to the block.

Rear Main Bearing Oil Seal Construction

The engine ***rear main bearing oil seal*** prevents oil leakage around the back of the crankshaft. There are several different types of rear oil seals. These include a two-piece neoprene seal, a one-piece neoprene seal, and a wick or rope seal.

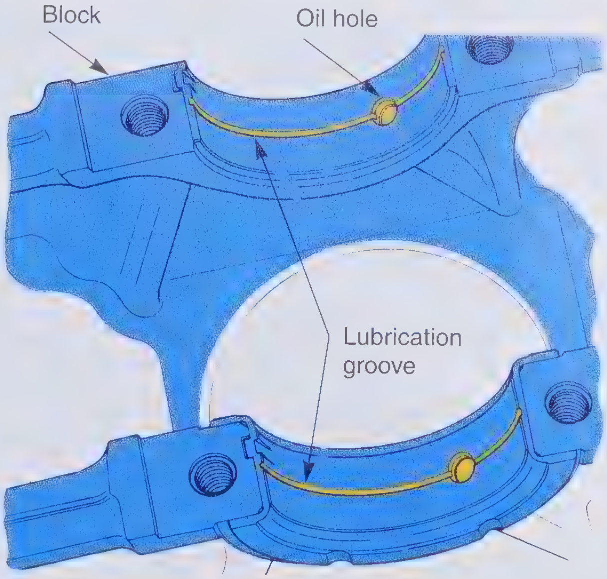

Figure 14-27. Main bearings have holes that let oil enter the bearing clearance. Grooves allow oil to circle the bearing to evenly distribute lubricating oil. (DaimlerChrysler)

A *two-piece neoprene rear oil seal* usually fits into a groove cut into the block and rear main cap. Look at **Figures 14-30** and **14-31.** The seal has a lip that traps oil and another lip that keeps dust and dirt out of the engine. The sealing lips ride on a machined surface of the crankshaft. Spiral grooves may be used on the crank surface to help throw oil inward, preventing leakage.

A *one-piece neoprene rear oil* seal fits around the rear flange on the crankshaft. **Figure 14-32** shows how a retainer may be used to hold the seal on the rear of the

engine. The one-piece rear seal has sealing lips that are similar to those on a two-piece neoprene seal.

A *rope,* or *wick, rear oil seal* is simply a woven rope filled with graphite. One piece of the rope seal fits into a groove in the block. Another piece fits in a groove in the main cap. This type seal is not as common as one- and two-piece neoprene seals.

Select-Fit Parts

Select-fit means that some engine parts are selected and installed in a certain position to improve the fit or clearance between parts. For example, pistons are commonly selected to fit precisely into their cylinders. To do so, the engine manufacturer measures the diameter of the cylinders. If one cylinder is machined slightly larger than another, a slightly larger piston is installed. Because of select-fit parts, it is important that you reinstall parts in their original locations whenever possible.

Balancer Shafts

Balancer shafts are used in some engines to cancel the vibrating forces produced by crankshaft, piston, and rod movement. They are usually found on 4- and 6-cylinder engines. **Figure 14-33** shows the balancer shafts used in one particular engine.

The balancer shafts, also called ***silencer shafts***, are installed in the right and left sides of the cylinder block. Usually, a chain is used to spin the shafts at twice crankshaft rpm. The shafts are supported on bearings fitted in a bore machined in the block. Oil is pressure-fed to these bearings to provide lubrication.

Workplace Skills

Reliability consists of being at work every day, arriving to work on time, and doing the job right. Reliability is your most important personality trait to an employer. Without it, you will have a difficult time keeping a good job and earning a good living as an auto repair technician.

Summary

- The basic parts of an engine bottom end are the block, crankshaft, connecting rods, and piston assemblies.
- Cylinder sleeves or liners are metal, pipe-shaped inserts that fit into the cylinder block.
- Line boring refers to a machining operation that cuts a series of holes through the block for the crankshaft bearings.
- A two-bolt main block only uses two bolts to secure each main bearing cap to the cylinder block. A four-bolt main block has four bolts holding each main cap.
- A main bearing bedplate is a large part that fits over the whole bottom of the block.
- A cam-ground piston is slightly out-of-round when viewed from the top.
- Piston taper is normally used to maintain the correct piston-to-cylinder clearance.
- A slipper skirt is produced when the portions of the piston skirt below the piston pin ends are removed.
- Piston ring width is the distance from the top of the ring to the bottom of the ring.

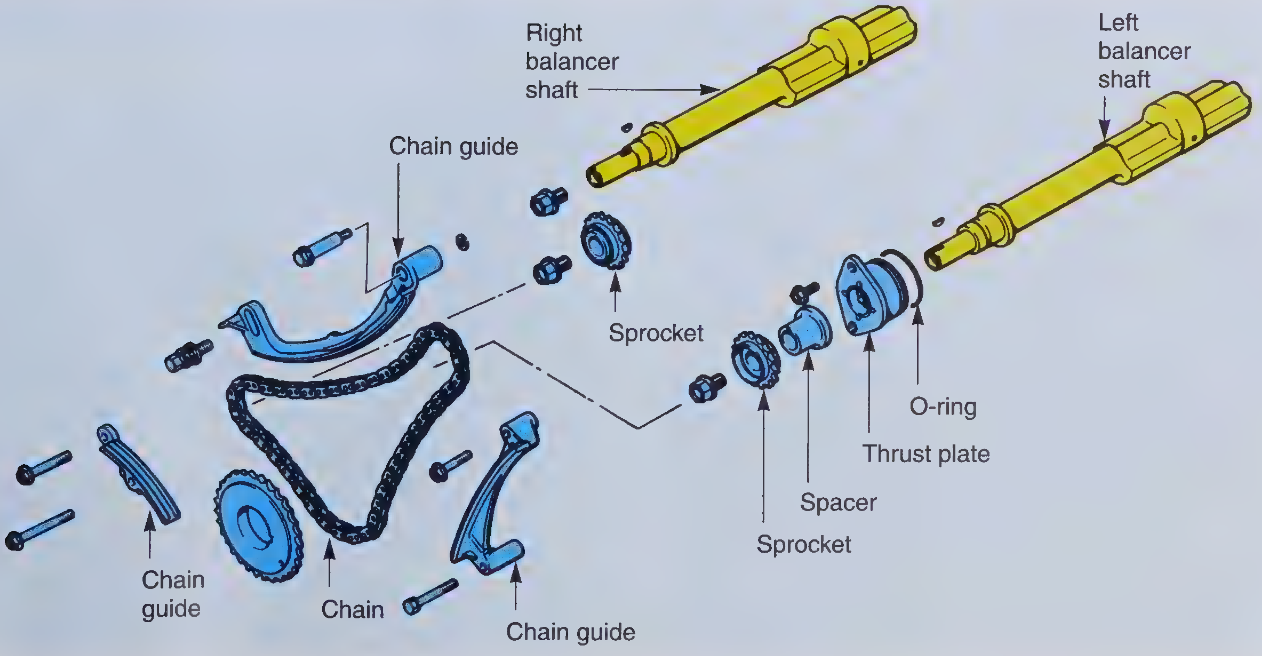

Figure 14-33. Balancer shafts are turned by a chain, sprockets, and the engine crankshaft. They counteract any vibration produced by the crankshaft, pistons, and rods.

- Piston ring gap is the distance between the ends of the ring when it is installed in the cylinder.
- Case-hardening is a heating and cooling process that increases the wear resistance of the piston pin.
- A full-floating piston pin is secured by snap rings and is free to rotate in both the rod and piston.
- A press-fit piston pin is forced tightly into the connecting rod's small end.
- Piston pin offset locates the piston pin hole slightly to one side of the piston centerline to quiet piston operation.
- Connecting rod numbers are used to ensure proper location of each connecting rod in the engine.
- A broken surface rod is scribed and broken off when manufactured to produce a rough, irregular mating surface between the rod body and cap.
- A standard bearing has the original dimensions specified by the engine manufacturer and is used for a new, unworn, or unmachined crankshaft.
- An undersize bearing is designed to be used on a crankshaft journal that has been machined to a smaller diameter.
- A main thrust bearing limits crankshaft end play.
- Select fit means that some engine parts are selected and installed in a certain position to improve the fit between parts.
- Balancer shafts are used in some engines to cancel the vibrating forces produced by crankshaft, piston, and rod movement.

Review Questions—Chapter 14

Please do not write in this text. Place your answers on a separate sheet of paper.

1. Cylinder blocks can be made of _____ _____ or _____.
2. Explain the difference between wet sleeves and dry sleeves.
3. Aluminum blocks commonly use _____ _____, _____ sleeves.
4. List and define six piston dimensions.
5. A(n) _____ _____ piston is machined slightly out-of-round to compensate for different rates of piston _____.
6. When the top of the piston outside diameter is machined slightly smaller than the bottom, it is called a:
   (A) pop-up piston.
   (B) dished piston.
   (C) cam-ground piston.
   (D) piston taper.
7. _____ _____ are small indentations either cast or machined in the piston top.
8. What is a ring expander-spacer?
9. The difference between the ring width and the width of the piston ring groove determines _____ _____ _____.
10. The difference between the ring wall thickness and ring groove depth determines _____ _____ _____.
11. Define ring gap.
12. When should you use piston rings with soft coatings?
13. Explain why some parts are case hardened.

14. Which of the following does *not* relate to modern piston assemblies?
    (A) Full-floating pin.
    (B) Press-fit pin.
    (C) Bolted piston pin.
    (D) Offset piston pin.
15. Describe piston slap and piston pin offset.
16. A(n) _____ on the head of a piston is used to indicate piston pin offset.
17. Name two reasons connecting rod numbers are used.
18. Engine crankshafts are usually made of _____ _____ or _____ _____.
19. How does lubricating oil get to the connecting rod bearings?
20. Which of the following does *not* pertain to engine bearings?
    (A) Load strength.
    (B) Lubrication absorption.
    (C) Conformability.
    (D) Embedability.
21. Explain bearing crush.
22. Explain bearing spread.
23. A(n) _____ bearing has the original dimensions specified by the manufacturer for a new, unworn, or unmachined crankshaft.
24. A(n) _____ bearing is designed to be used on a crankshaft journal that has been machined to a smaller diameter.
25. Describe three rear main oil seal variations.

ASE-Type Questions

1. Which of the following is *not* a basic part of an engine bottom end?
    (A) Block.
    (B) Valve train.
    (C) Crankshaft.
    (D) Connecting rods.
2. A piston head can reach operating temperatures as high as:
    (A) 450°F.
    (B) 500°F.
    (C) 650°F.
    (D) 700°F.
3. The distance from the piston pin hole centerline to the piston top is called:
    (A) skirt length.
    (B) piston diameter.
    (C) pin hole diameter.
    (D) compression distance.
4. The piston type commonly used with a wedged cylinder head is:
    (A) concave.
    (B) pop-up.
    (C) flat top.
    (D) All of the above.
5. Which of the following provides clearance between the piston and crankshaft counterweights?
    (A) Slipper skirt.
    (B) Piston taper.
    (C) Valve reliefs.
    (D) Compression rings.
6. The most common oil rings consist of:
    (A) two rails and a spacer.
    (B) ten slots and a spacer.
    (C) three rails and an expander.
    (D) seven slots and an expander.
7. The difference between piston ring width and ring groove width determines:
    (A) ring gap.
    (B) ring side clearance.
    (C) ring wall thickness.
    (D) ring back clearance.
8. The purpose of a drilled connecting rod is to:
    (A) rotate the piston pin.
    (B) create piston pin offset.
    (C) prevent pressure leakage.
    (D) supply oil to the piston pin.
9. How many connecting rods bolt to each crankshaft journal in a V-type engine?
    (A) One.
    (B) Two.
    (C) Three.
    (D) Four.
10. Basic types of engine bearings include each of these *except:*
    (A) piston bearings.
    (B) camshaft bearings.
    (C) crankshaft bearings.
    (D) connecting rod bearings.

Activities for Chapter 14

1. Use inside and outside micrometers to measure the diameter of a piston and the engine cylinder bore. Then, find the amount of piston clearance by subtracting the piston diameter from the bore measurement.
2. If a number of pistons are available, determine whether any are cam ground. Do this by measuring the diameter parallel to the piston pin, and then measuring the diameter perpendicular (at a 90° angle) to the piston pin. If the piston is cam ground, the measurement perpendicular to the pin will be larger by a few thousandths of an inch.
3. Disassemble a rod cap from its connecting rod, turn it end-for-end so the numbers no longer align, and bolt it back into place. Can you visually detect an "out-of-round" rod bore? If not, try to think of a way to determine whether the bore is perfectly round. When finished with this activity, reassemble the rod and cap properly.

15 Engine Front End Construction

After studying this chapter, you will be able to:

- Explain the function and construction of a vibration damper.
- Compare the three types of camshaft drives.
- Explain the construction of a timing gear, timing chain, and timing belt assembly.
- Summarize the construction of engine front covers, oil slingers, and other related components.
- Describe safety practices related to working on engine front end components.
- Correctly answer ASE certification test questions on engine front end construction.

The typical ***engine front end*** assembly consists of the parts that attach to the front of the engine. These parts include the camshaft drive mechanism, front cover-mounted oil pumps, water pumps, auxiliary shafts, etc.

This chapter explains the construction and operation of engine front end assemblies. Study it carefully. It will help you understand later chapters on service and repair.

Note!
Oil pumps, water pumps, and other front end–related parts are detailed in other textbook chapters. Refer to the index for more information on these components.

Vibration Damper Construction

Harmonic vibration is a high-frequency movement resulting from twisting and untwisting of the crankshaft. Each piston and rod assembly can exert over a ton of downward force on its journal. This can actually flex, or bend, the crank throws in relation to each other. If harmonic vibration is not controlled, the crankshaft could vibrate like a musician's tuning fork or a string-type musical instrument. Serious engine damage, usually a broken crankshaft, can result.

A ***vibration damper,*** or ***harmonic balancer,*** is used to control harmonic vibration. The vibration dampener also cuts load variation on the engine timing belt, chain, or gears, so these parts last longer.

The vibration damper is a heavy wheel mounted on a rubber ring to control harmonic vibration. Look at **Figure 15-1.** The balancer is keyed to the crankshaft snout. This makes the damper spin with the crankshaft. **Figure 15-2** illustrates the basic construction of a typical vibration damper. Notice how a rubber ring separates the outer ***inertia ring*** and the inner sleeve. The inertia ring and the rubber ring set up a damping action on the crankshaft as it tries to twist and untwist. This deadens vibrating action.

A ***dual-mass harmonic balancer*** has one weight mounted on the outside of the crankshaft pulley and another on the inside. The extra rubber-mounted weight helps reduce vibration at high engine speeds.

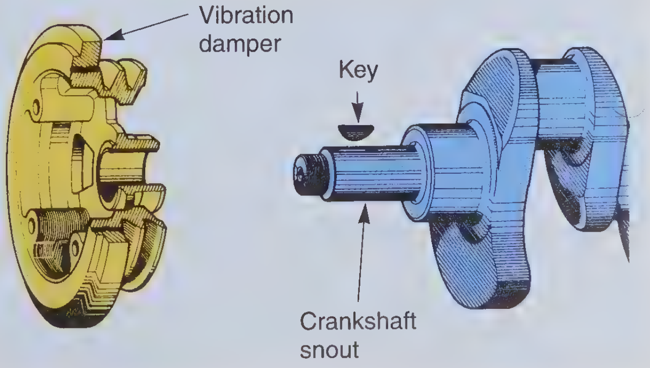

Figure 15-1. The vibration damper, or harmonic balancer, installs on the front of the crank. A key locks the damper to the crank snout. A large bolt is commonly used to hold the damper in place.

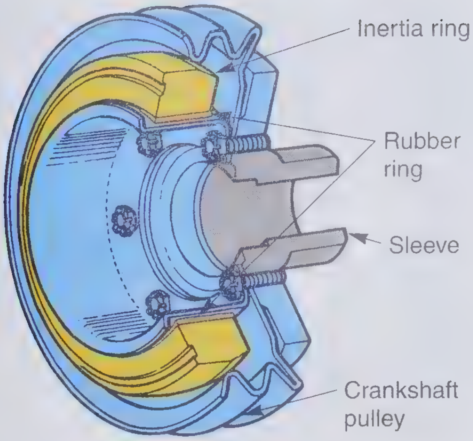

Inertia ring
Rubber ring
Sleeve
Crankshaft pulley

Figure 15-2. Study the construction of a vibration damper. A rubber ring separates the inertia ring and inner sleeve. This acts to deaden, or cancel, crankshaft harmonic vibration. (DaimlerChrysler)

Crankshaft Pulley

The *crankshaft pulley* operates belts for the alternator, water pump, and other units. As shown in **Figure 15-2,** it is often part of the harmonic balancer. It may also simply be bolted to the front of the balancer. The pulley has either V or ribbed grooves for the belts.

Camshaft Drive Construction

A *camshaft drive* must turn the camshaft at one-half of the crankshaft speed. It must do this smoothly and dependably. There are three basic types of camshaft drives: timing gears, a timing chain and sprockets, or a timing belt and sprockets.

Timing Gears

Timing gears are common in engines used for heavy-duty applications, such as taxicabs or trucks. They are very dependable and long lasting. However, they are noisier than a chain or belt drive. Gears are primarily used in cam-in-block engines where the crankshaft is close to the camshaft.

Two *timing gears* are used to drive the engine camshaft. A crank gear is keyed to the crankshaft snout, as shown in **Figure 15-3.** It turns a cam gear on the end of the camshaft. The cam gear is twice the size of the crank gear. This results in the desired 2:1 reduction.

Timing marks on the two gears show the technician how to install the gears properly. Refer to **Figure 15-3.** The marks may be circles, indentations, or lines on the gears. The timing marks must line up for the camshaft to be in time with the crankshaft.

Figure 15-3. A timing gear setup is very dependable. The crank gear turns the cam gear at one-half of the crank speed. Timing marks allow for the proper assembly of the gears. (Chevrolet)

Timing Chain and Sprockets

A *timing chain* and *sprockets* can also be used to turn the camshaft. See **Figure 15-4.** This is the most common type of camshaft drive arrangement on cam-in-block engines. It may also be used in OHC engines.

A *crank sprocket* is keyed to the crankshaft snout. A larger cam sprocket, with either metal or plastic teeth,

bolts to the camshaft. The timing chain transfers power from the crank sprocket to the cam sprocket. Like timing gears, the chain sprockets have timing marks. The marks must line up to properly time the camshaft with the crankshaft.

A ***chain guide*** may be needed to prevent chain slap. ***Chain slap*** occurs when the chain flaps back and forth because of excessive slack in the chain. **Figure 15-5** shows a timing chain using chain guides. The guides have a metal body with either a plastic or Teflon® face. This allows the chain to slide on the guide with minimum friction and wear.

A ***chain tensioner*** may be used to take up the slack in the chain as it and the sprockets wear, **Figure 15-5.** It is usually a spring-loaded plastic or fiber block. The spring pushes the block outward, keeping a constant tension on the chain. A chain-type cam drive for an OHC engine commonly uses guides and sometimes a tensioner. Refer to **Figure 15-6** for a front view of this setup.

Crankshaft

Figure 15-7. A side view of a diesel engine using both a timing chain and an auxiliary drive chain. (DaimlerChrysler)

Auxiliary Chain

An ***auxiliary chain*** may be used to drive the engine oil pump, balancer shafts, and other units on the engine. **Figures 15-6** and **15-7** show two examples. An auxiliary chain is driven by an extra sprocket, usually placed in front of the crankshaft timing chain sprocket. Do *not* confuse an auxiliary chain with a timing chain.

Engine Front Cover Construction

An ***engine front cover,*** also called a ***timing cover,*** encloses the timing chain or gear mechanism and prevents oil leakage from the front of the engine. As pictured in **Figure 15-8,** the front cover bolts to the front of the engine block. The cover holds the front oil seal, timing pointer, probe holder, and other parts.

A ***front oil seal*** prevents oil leakage between the crankshaft and the front cover. The seal is press-fit in the cover.

An engine front cover is commonly made of thin, stamped steel or cast aluminum. Sometimes the water pump bolts onto the front cover. Some water pump housings are cast into the front of the engine block. The core of the pump bolts onto the block housing. The oil pump may also be housed in the front cover, **Figure 15-9.**

Oil Slinger

An ***oil slinger*** is a washer-shaped part that fits in front of the crankshaft sprocket. Refer back to **Figure 15-8.** When the engine is running, oil squirts out of the front

main bearing and strikes the spinning slinger. Centrifugal force then throws the oil outward and onto the timing chain or gears. The oil slinger not only helps lubricate the timing mechanism, but it blocks the oil from striking the front seal, preventing leakage.

Timing Belt and Sprockets

A timing belt drive mechanism basically consists of a crank sprocket, cam sprocket, timing belt, and belt tensioner. It is used to drive the camshaft on OHC engines. Look at **Figure 15-10.**

A ***timing belt*** provides a very smooth and accurate method of turning the camshaft. The timing belt and the sprockets have cogged, or square, teeth that prevent belt slippage. Some timing belts are made of fiberglass-reinforced nitrile rubber for increased strength and durability. Some are designed for a service life of over 100,000 miles (160,000 km) if not damaged by road debris or oil.

The ***timing belt sprockets*** are usually made of cast iron or aluminum, **Figure 15-10.** The crank sprocket is keyed to the crankshaft snout. The cam sprocket normally bolts to the front of the camshaft. A dowel pin may be used to position the cam sprocket correctly. Belt sprockets have timing marks, just like timing gears and chain sprockets. The marks must be aligned with specific points on the engine. This will properly time the opening of the engine valves.

Alternator belt

Figure 15-10. Study the parts that install on the front of this OHC engine. Cogged sprockets are used with the cam timing belt. A V-belt operates in the crank pulley. A belt cover surrounds the timing belt and sprockets. (Honda)

A ***belt tensioner*** is a spring-loaded wheel that keeps the timing belt firmly seated on its sprockets. Illustrated in **Figure 15-11,** the tensioner pushes inward on the back of the belt. This prevents the belt teeth from slipping on the sprocket teeth. The tensioner wheel is mounted on an antifriction bearing. This bearing is filled with grease and permanently sealed at the factory.

Some belt tensioners use both spring tension and hydraulic pressure to maintain belt tightness on its sprockets. The spring tension keeps the belt tight when the engine is shut off. The hydraulic pressure adjusts the belt tension with engine speed. At higher rpms, belt tension is increased to keep the belt from slipping or flying off.

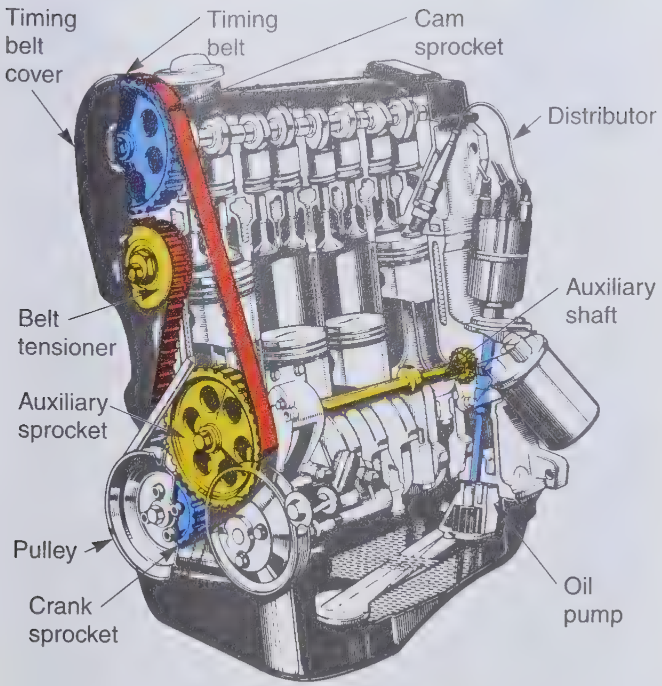

Figure 15-11. A cutaway view of an OHC engine using an auxiliary drive shaft. An auxiliary sprocket turns the shaft. The shaft also has a small gear for operating the ignition distributor and oil pump. (DaimlerChrysler)

The timing belt may also be used to drive the oil pump, diesel injection pump, or ignition distributor. **Figure 15-11** shows an engine in which the timing belt drives an auxiliary shaft. The shaft is then used to operate the distributor and oil pump.

Timing Belt Cover

A timing belt cover simply protects the belt from damage and the technician from injury. It is made from sheet metal or plastic. See **Figures 15-10** and **15-11.** A gasket may seal the mating surfaces between the timing belt cover and the block. Timing belt covers are tightly sealed at the bottom to keep road debris and water off the rubber belt. If ice forms on the belt sprocket, it can cause the belt to jump off its sprockets, upsetting valve timing. This can lead to severe engine damage.

Tech Tip!
A timing belt cover should not be confused with an engine front cover. A timing belt cover does *not* contain oil or an oil seal.

Duff's Garage

Problem: Mr. Washington brought his 1996 Lexus into the shop, complaining of a knocking sound that seemed to be coming from the engine.

Diagnosis: After asking Mr. Washington to describe the problem, Duff, the shop owner, asks specific questions about the knocking noise. He asks if the problem is the same at all engine temperatures. Mr. Washington says the knock is the same with engine cold or hot but adds that the engine seems to knock more at idle than at other speeds.

Duff starts the overhead-cam engine and notices a light rattle that seems to be coming from around the front of the engine. He passes this information along to one of the shop's ASE-certified engine repair technicians.

The technician uses a stethoscope to help pinpoint the source of the noise. He touches the tip of the stethoscope to various points on the engine to find the area emitting the loudest noise. The knock seems loudest on the sides of the timing chain cover. The technician suspects that the timing chain is hitting on the inside of the aluminum cover. He disassembles the front of engine for further inspection and discovers that the timing chain guides and the chain itself are badly worn. Marks inside the front cover serve to confirm the technician's suspicions: the worn timing chain is indeed striking the front cover.

Repair: The technician installs a new timing chain and chain guides. He also changes the oil and filter, since the oil looked very dark and dirty. When Mr. Washington returns to the shop to pick up the vehicle, the technician explains the cause of the problem and reminds him to the change oil at the recommended intervals to prevent excess engine wear.

Summary

- The typical engine front end assembly consists of the parts that attach to the front of the engine.
- Harmonic vibration is a high-frequency movement resulting from twisting and untwisting of the crankshaft.
- A vibration damper, also called a harmonic balancer, is a heavy wheel mounted in rubber to control harmonic vibration.

- The crankshaft pulley operates belts for the alternator, water pump, and other units.
- Timing gears are two gears that operate the engine camshaft.
- A timing chain and sprockets can be used to turn the camshaft.
- A chain guide may be needed to prevent chain slap.
- A chain tensioner may be used to take up slack as the chain and sprockets wear.
- A front oil seal prevents oil leakage between the crankshaft and cover.
- A timing belt mechanism basically consists of a crank sprocket, cam sprocket, timing belt, and belt tensioner.

Review Questions—Chapter 15

Please do not write in this text. Place your answers on a separate sheet of paper.

1. Define the term "crankshaft harmonic vibration."
2. A(n) _____ _____ is a heavy wheel mounted on a rubber ring to control harmonic vibration.
3. The _____ _____ operates belts for the alternator, water pump, and other units.
4. A camshaft drive must turn the camshaft at _____ crankshaft speed.
5. Which of the following does *not* refer to timing gears?
   (A) Used on heavy-duty applications.
   (B) Dependable and long lasting.
   (C) Very quiet.
   (D) All of the above.
6. The most common camshaft drive setup for cam-in-block engines consists of a(n) _____ _____ and set of _____ .
7. Why is a chain guide used?
8. Explain the function of a chain tensioner.
9. What does an auxiliary chain commonly drive?
10. Is an engine front cover the same as a timing belt cover?

ASE-Type Questions

1. High-frequency movement resulting from the twisting and untwisting of the crankshaft is called:
   (A) engine knock.
   (B) after-running.
   (C) oscillating vibration.
   (D) harmonic vibration.
2. Which of the following is used to control the high-frequency movement that results from crankshaft twisting?
   (A) Vibration damper.
   (B) Crankshaft pulley.
   (C) Harmonic balancer.
   (D) Both A and C.
3. Which of the following normally operates belts for the alternator, water pump, and other units?
   (A) Auxiliary chain.
   (B) Timing sprockets.
   (C) Vibration damper.
   (D) Crankshaft pulley.
4. All of the following are basic types of camshaft drives *except:*
   (A) rod drive.
   (B) belt drive.
   (C) gear drive.
   (D) chain drive.
5. A camshaft drive must turn the camshaft at:
   (A) twice crankshaft speed.
   (B) crankshaft speed.
   (C) one-half crankshaft speed.
   (D) None of the above.
6. The two gears that operate the camshaft are the:
   (A) helical and spur gears.
   (B) crank and camshaft gears.
   (C) countershaft and crank gears.
   (D) cam sprocket and pulley gears.

7. Which of the following transfers power from the crank sprocket to the cam sprocket?
   (A) *Spur gear.*
   (B) *Timing belt.*
   (C) *Timing chain.*
   (D) *Timing gears.*
8. Which of the following devices is used to prevent chain slap?
   (A) *Chain guide.*
   (B) *Auxiliary chain.*
   (C) *Timing sprocket.*
   (D) *Chain link.*
9. A timing belt mechanism contains each of the following *except:*
   (A) *timing belt.*
   (B) *belt damper.*
   (C) *cam sprocket.*
   (D) *belt tensioner.*
10. The washer-shaped part that fits directly in front of the crankshaft sprocket is the:
   (A) *pulley.*
   (B) *damper.*
   (C) *retainer.*
   (D) *oil slinger.*

Activities for Chapter 15

1. On an engine with the timing cover removed, locate the timing marks on the crankshaft and camshaft pulleys, gears, or sprockets. If the engine can be rotated by hand, determine whether the timing marks align properly.
2. Sketch a front-end view of an engine with a timing chain or timing belt. Show the belt or chain path and label the sprockets that the chain or belt engages.

16 Engine Size and Performance Measurements

After studying this chapter, you will be able to:

- Describe engine size measurements based on bore, stroke, displacement, and number of cylinders.
- Explain engine compression ratio and how it affects engine performance.
- Explain engine torque and horsepower ratings.
- Describe the different methods used to measure and rate engine performance.
- Explain volumetric efficiency, thermal efficiency, mechanical efficiency, and total engine efficiency.
- Follow safe practices when making engine performance measurements.
- Correctly answer ASE certification test questions on engine size and performance measurements.

Engine size and performance measurements are important to the technician. Shop manuals list many engine size and performance values for specific engines. You must be able to understand this information to properly communicate with others.

Engine Size Measurement

Engine size is determined by the number of cylinders, the cylinder diameter, and the amount of piston travel per stroke. Any of these variables can be changed to alter engine size. Engine size information is used when ordering parts and when measuring wear during major engine repairs.

Bore and Stroke

Cylinder bore is the diameter of the engine cylinder. See **Figure 16-1.** It is measured across the cylinder, parallel with the top of the block. Cylinder bores vary in size, but they typically range from 3–4″ (75–100mm).

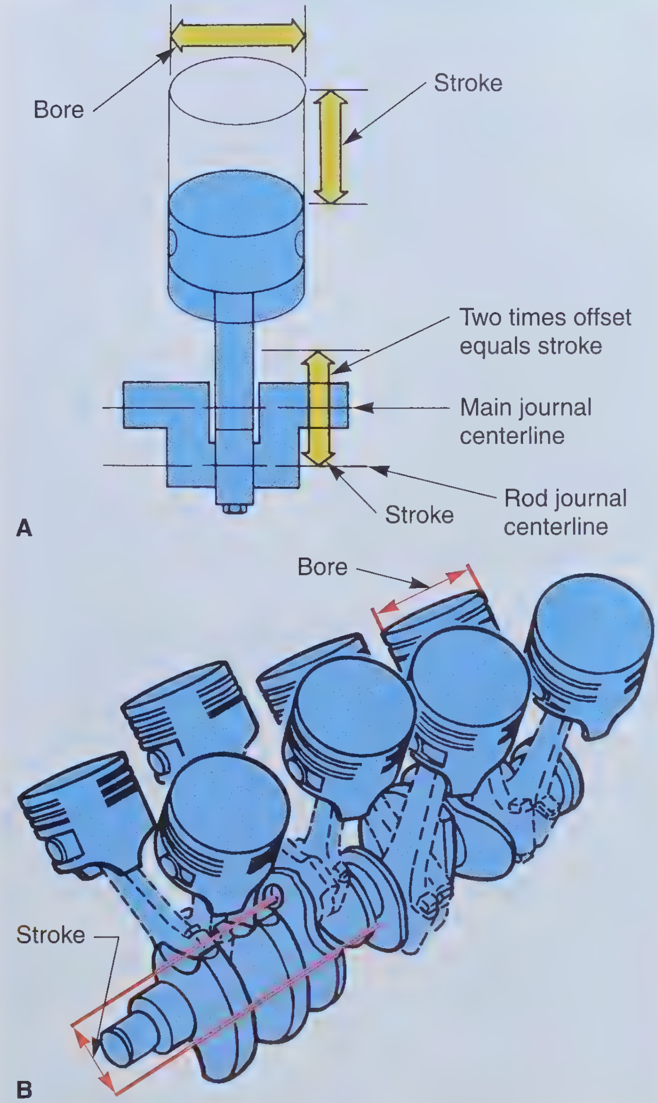

Figure 16-1. Bore and stroke measurements. A—Cylinder bore is measured across the cylinder, parallel with the deck of the engine block. Piston stroke is the distance the piston moves from BDC to TDC. Piston displacement is the amount of volume the piston moves in one upward stroke. B—Engine displacement is the displacement for all the pistons. (Ford)

Piston stroke is the distance the piston moves from top dead center (TDC) to bottom dead center (BDC), **Figure 16-1.** The amount of throw (offset) built into the crank rod journal controls the piston stroke. The stroke also varies from about 3–4″ (75–100mm) in an automotive engine.

A shop manual normally gives bore and stroke specifications. For instance, suppose a specification for bore and stroke is given as 4.00″ × 3.00″. This means that the engine cylinder is 4″ in diameter and the piston stroke is 3″. Bore is always the first value given and stroke is the second.

Generally, a larger bore and a longer stroke make an engine more powerful. It can pull in more fuel and air on each intake stroke. As a result, more combustion pressure is exerted on the head of the piston during the power stroke. To improve fuel economy and reduce emissions, the trend is toward smaller, more efficient engines.

Piston Displacement

Piston displacement is the volume the piston displaces (moves) as it travels from BDC to TDC. It is found by comparing cylinder diameter and piston stroke. A large cylinder diameter and large piston stroke produce a large piston displacement.

Piston displacement is calculated using a simple formula:

$$\text{piston displacement} = \frac{\text{bore squared} \times 3.14 \times \text{stroke}}{4}$$

Example: If an engine has a bore of 4″ and a stroke of 3″, what is its piston displacement?

Solution:

$$\text{piston displacement} = \frac{(4''^2) \times 3.14 \times 3''}{4}$$

$$= \underline{37.68 \text{ cu. in.}}$$

Engine Displacement

Engine displacement, or ***engine size,*** is the volume displaced by all the pistons in an engine (piston displacement multiplied by the number of engine cylinders). For example, if one piston displaces 25 cu. in. and the engine has four cylinders, the engine displacement would be 100 cu. in. (25 × 4 = 100).

Cubic inch displacement (CID), cubic centimeters (cc), and ***liters (L)*** are units of engine displacement. For example, a V-8 engine might have a 350 CID. A V-6 could be a 3.3 L engine. A four-cylinder engine might have a displacement of 2300 cc. Since one liter equals 1000 cc, a 2 liter engine would have 2000 cc.

Engine displacement is usually matched to the weight of the vehicle. A heavy car, truck, or van needs a large engine, which produces a great deal of power. A light, economy car only needs a small, low-power engine for adequate acceleration.

Force, Work, and Power

Force is a pushing or pulling action. When a spring is compressed, an outward movement and force is produced. Force is measured in pounds or newtons.

Work is done when force causes movement. If a compressed spring moves another engine part, work has been done. If the spring does not cause movement, no work has been done. Work is measured in foot-pounds, or joules. The formula for work is:

work = distance moved × force applied

Example: If you use a hoist to lift a 400 lb engine 3′ in the air, how much work has been done?

Solution: work = 3′ × 400 lb
= 1200 foot pounds (ft lb)

Power is the rate, or speed, at which work is done. It is measured in foot-pounds per second or per minute. The metric unit for power is the watt (kilowatt).

High power output can do a large amount of work. Lower power can only do a small amount of work. The formula for power is:

$$\text{power} = \frac{\text{distance (feet)} \times \text{force (pounds)}}{\text{time (minutes)}}$$

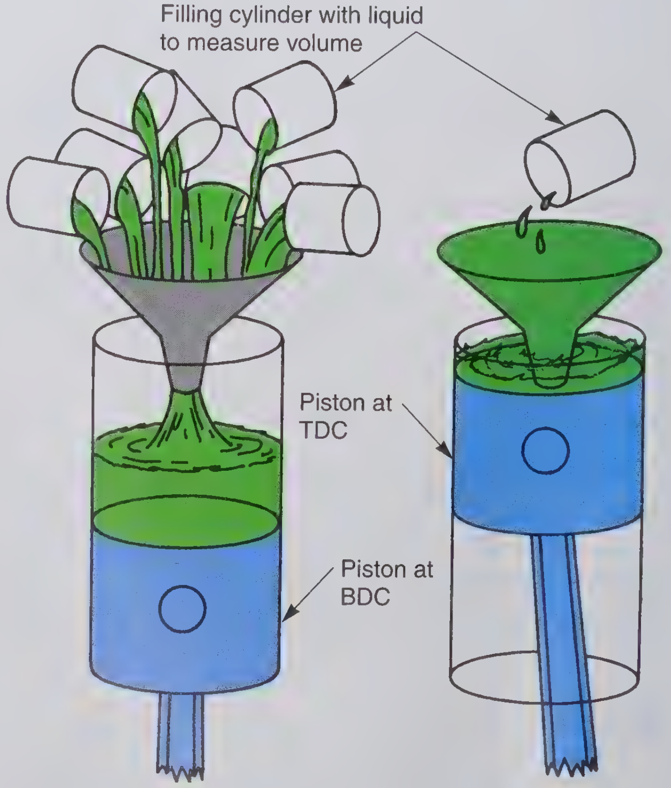

Figure 16-2. Compression ratio is a comparison of cylinder volumes with the piston at TDC and BDC. This engine has eight times the volume at BDC, producing an 8:1 compression ratio.

Example: If an engine moves a 3000 lb car 1000′ in one minute, how much power is needed?

Solution:

$$\text{power} = \frac{1000' \times 3000 \text{ lb}}{1 \text{ min.}}$$

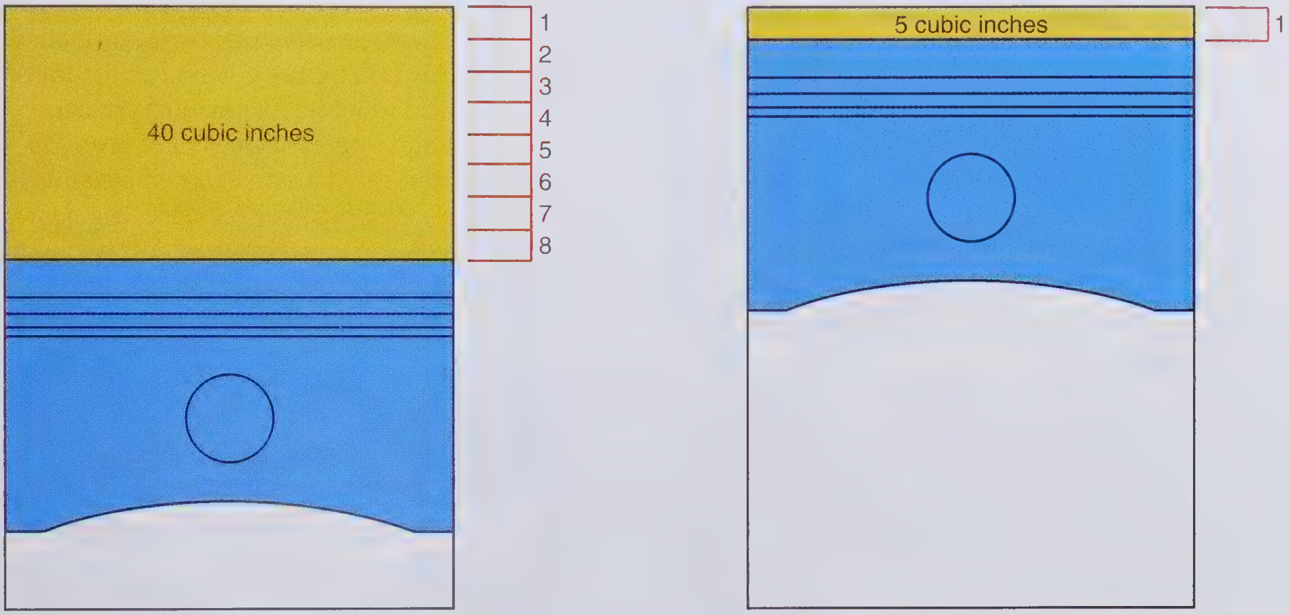
$$= \frac{3{,}000{,}000 \text{ ft lb}}{\text{min.}}$$

Compression Ratio

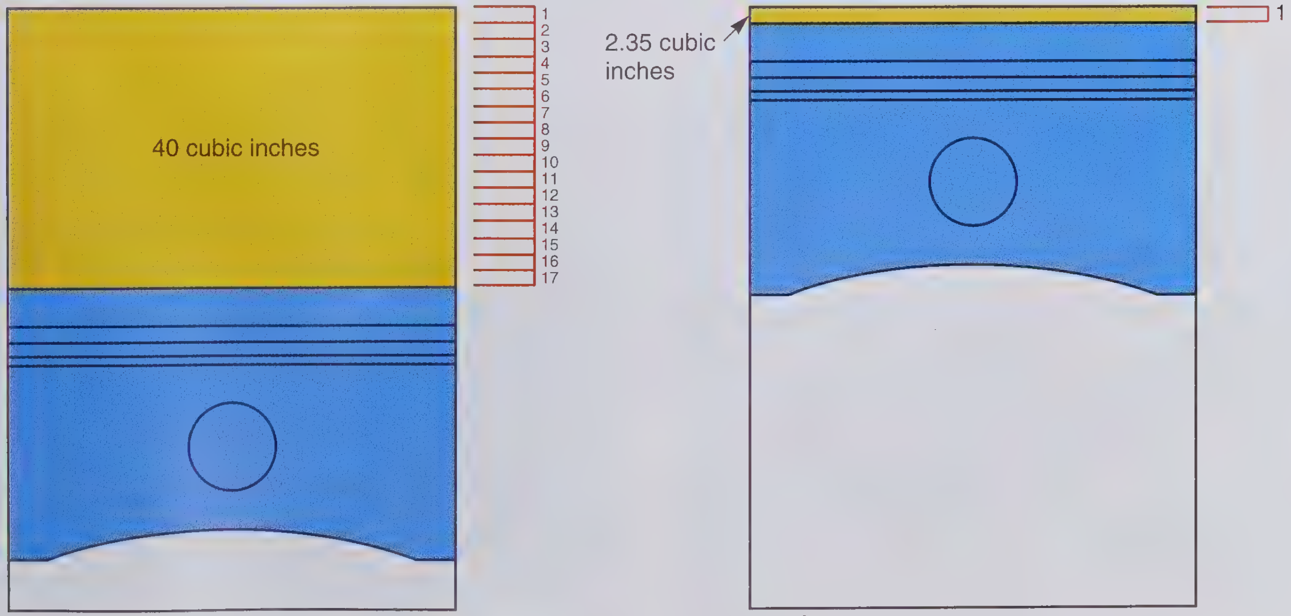
Engine compression ratio compares the cylinder volume with the piston at TDC to the cylinder volume with the piston at BDC. Look at **Figure 16-2.** An engine's compression ratio partially determines how much the air-fuel mixture is pressurized, or squeezed, on the compression stroke.

A compression ratio is given as two numbers. For example, an engine may have a compression ratio of 9:1 (9 to 1). This means the maximum cylinder volume is nine times as large as the minimum cylinder volume. At BDC, a cylinder has maximum volume. Minimum cylinder volume occurs at TDC.

Figure 16-3 illustrates two examples of compression ratios. When the gasoline engine piston is at BDC, the cylinder volume is 40 cu. in. (0.65 L). When the piston



Gasoline engine = 8:1 compression ratio



Diesel engine = 17:1 compression ratio

Figure 16-3. A diesel engine has a much higher compression ratio than a gasoline engine. A diesel must squeeze the fuel mixture very tight to cause combustion.

slides to TDC, the volume is reduced to 5 cu. in. (0.08 L). Dividing 40 by 5 (0.65 by 0.08), the compression ratio for this engine would be 8:1.

High-performance automotive engines manufactured in the 1960's had very high compression ratios from the factory. They were designed to run on high-octane leaded gasoline. These "muscle car engines" had stock compression ratios as high as 11 or 12:1.

When lead was phased out of gasoline for environmental reasons, automakers started reducing compression ratios to improve driveability. However, today's "high-tech" engines are again being designed with relatively high compression ratios. Late-model, naturally aspirated, high-performance engines can now have compression ratios as high as 10:1.

Factory supercharged and turbocharged engines have a lower compression ratio (usually about 7 or 8:1) than naturally aspirated engines (no blower to increase intake manifold pressure). The supercharger or turbocharger forces the fuel charge into the engine. The lower compression ratio allows more fuel charge into the combustion chamber. In effect, the blower raises the compression ratio of the engine to provide fuel charge compression and good combustion.

Diesel engines have a very high compression ratio compared to engines designed to burn gasoline. Typical compression ratios for diesel engines range from 17:1 for automotive diesel engines to 25:1 for industrial diesels. Being a compression-ignition engine, the fuel charge must be pressurized until it is hot enough to burn. Unlike a gasoline engine, no spark plug is used to produce an electric arc to start combustion. Compression pressure alone must start combustion of the fuel.

Note!
Automotive fuels and combustion are detailed in Chapter 20, *Automotive Fuels, Gasoline and Diesel Combustion.*

Compression Pressure

Compression pressure is the amount of pressure in the cylinder on the compression stroke. Compression pressure is normally measured in pounds per square inch (psi) or kilopascals (kPa).

A gasoline engine has compression pressure from 130–180 psi (900–1200 kPa). A diesel engine has a much *higher* compression pressure of about 250–400 psi (1700–2800 kPa). Service specifications will give the exact compression pressure for a specific engine.

A ***compression gauge*** is used to measure compression pressure. The gauge is screwed into the spark plug, injector nozzle, or glow plug hole. The ignition or injection system (whichever contains the removed part) is disabled. Then, the engine is cranked over. The gauge measures the compression pressure.

Compression pressure is an indicator of engine condition. If it is low, something is allowing air to leak out of the cylinder. The engine may have bad rings, burned valves, or a blown head gasket.

Engine Torque

Torque is a turning, or twisting, force. When you turn a steering wheel or tighten a belt, you have applied torque.

Engine torque is a rating of the turning force at the engine crankshaft. When combustion pressure pushes the piston down, a strong rotating force is applied to the crankshaft. This turning force is sent to the transmission or transaxle, and to wheels, propelling the car.

Engine torque specifications are given in a shop manual. An example of a torque specification is 450 ft lb @ 3000 rpm. This high-performance engine would be capable of producing a maximum of 450 ft lb of torque at an operating speed of 3000 revolutions per minute. In metrics, engine torque is often stated in newton-meters (N•m).

Horsepower

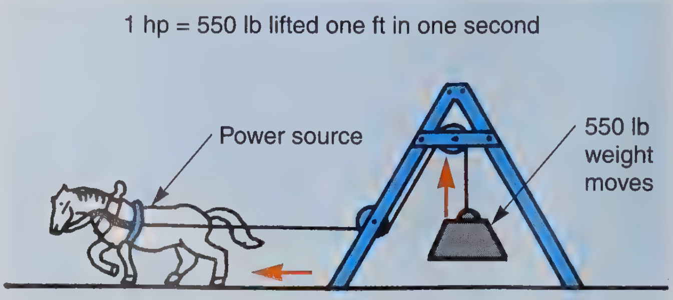
Horsepower (hp) is a measure of an engine's ability to perform work (power). At one time, one horsepower was the approximate strength of a horse, **Figure 16-4.** A 300 hp engine could theoretically do the work of 300 horses.

One horsepower equals 33,000 ft lb of work per minute. To find engine horsepower, use the following formula:

$$\text{hp} = \frac{\text{work (ft lb)}}{33{,}000}$$

or

$$\text{hp} = \frac{\text{distance (ft)} \times \text{weight (lb)}}{33{,}000}$$



1 hp = 550 lb lifted one ft in one second
Power source
550 lb weight moves

Figure 16-4. This represents one horsepower. In automotive work, one horsepower equals 33,000 lb moved one foot in one minute.

Example: For a small engine to lift 500 lb a distance of 700′ in one minute, about how much horsepower would be needed?

Solution:

$$\text{hp} = \frac{700' \times 500 \text{ lb}}{33{,}000} = 10.6 \text{ hp}$$

Factory Horsepower Ratings

Automobile makers rate engine power at a specific engine speed. For instance, a high-performance, supercharged engine might be rated at 400 hp @ 5000 rpm. This engine power rating is normally stated in a service manual or sales literature. There are several different methods of calculating engine horsepower.

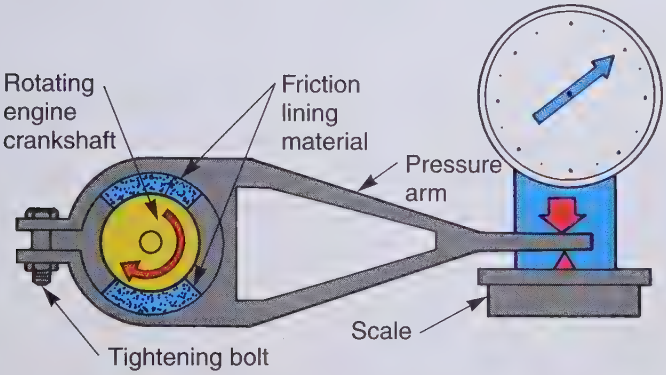


Figure 16-5. A prony brake measures engine brake horsepower. A brake is applied to the engine crankshaft. The amount of needle deflection can be used to find horsepower.

Figure 16-6. A technician is using an engine dynamometer to measure engine performance. The dyno loads the engine to simulate driving conditions while monitoring horsepower output, fuel efficiency, emissions, and many other engine functions. (MSD Ignition Systems)

Brake horsepower (bhp) measures the usable power at the engine crankshaft. Shown in **Figure 16-5,** a prony brake was first used to measure brake horsepower. The engine turns the prony brake when the braking mechanism is applied, producing a force on the scale. The resulting amount of pointer deflection is then used to find brake horsepower.

An ***engine dynamometer (dyno)*** is used to measure the brake horsepower of modern car engines. Refer to **Figure 16-6.** It functions in much the same way as a prony brake. Either an electric motor or a fluid coupling is used to place a drag on the engine crankshaft. Then, power output can be determined.

A ***chassis dynamometer*** measures the horsepower delivered to the drive wheels. See **Figure 16-7.** It indicates the amount of horsepower available to propel the car.

Indicated horsepower (ihp) refers to the amount of power formed in the engine combustion chambers. A special pressure-sensing device is placed in the cylinder. The pressure readings are used to determine the indicated horsepower.

Frictional horsepower (fhp) is the power needed to overcome engine friction. It is a measure of the resistance to movement between engine parts, or power lost to friction. It reduces the amount of power left to propel the car.

Net horsepower, or SAE net horsepower, is the maximum power developed when an engine is loaded by all accessories (alternator, water pump, fuel pump, air injection pump, air conditioning, and power steering pump). Net horsepower indicates the amount of power available to move the car. See **Figure 16-8.**

Gross horsepower (ghp) is similar to net horsepower, but it is the engine power available with only basic

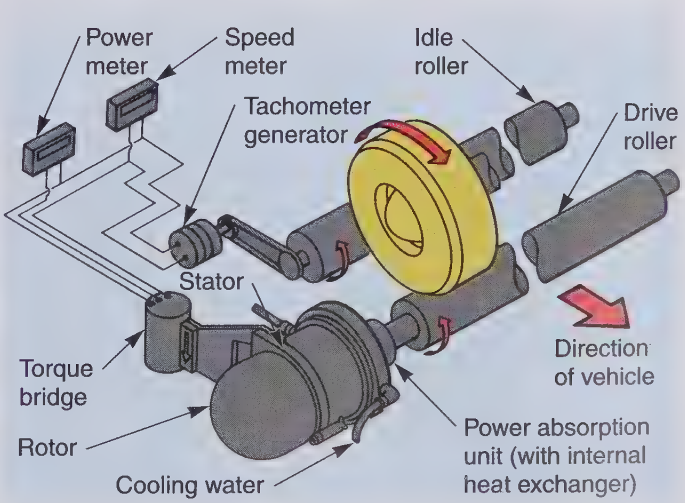

Figure 16-7. A chassis dynamometer measures turning power at the drive wheels. This accounts for any power consumed by the drive train. (Clayton)

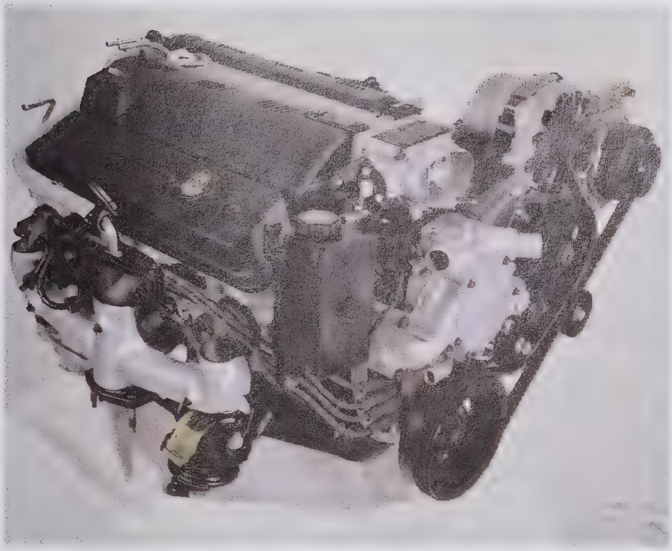

Figure 16-8. Net horsepower is the available horsepower with the engine operating all accessories. (Chevrolet)

accessories installed (alternator, fuel pump, and water pump). Gross horsepower does *not* include the power lost to the power steering pump, air injection pump, air-conditioning compressor, or other extra units. Look at **Figure 16-9.**

Taxable horsepower is simply a general rating of engine size. In many states, it is used to find the tax placed on a car. The formula for taxable horsepower (thp) is:

thp = bore squared × number of cylinders × 0.4

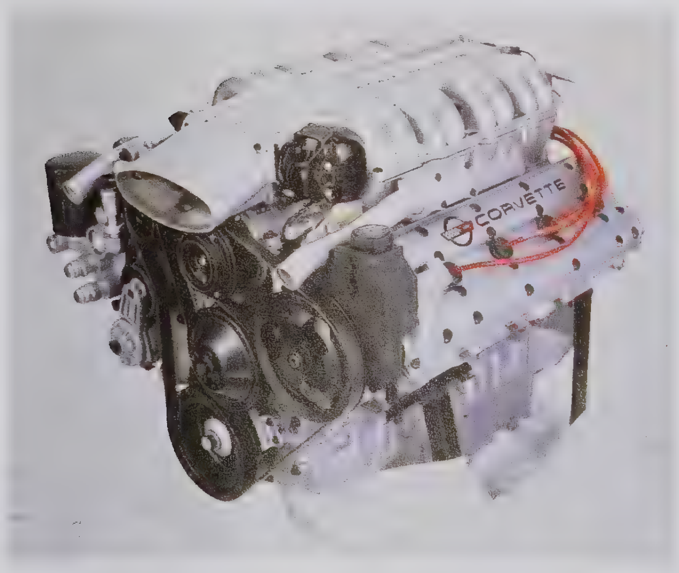

Figure 16-9. Gross horsepower is similar to net horsepower, but it does not include power lost to unneeded accessories. (Chevrolet)

Engine Efficiency

Engine efficiency is the ratio of usable power at the engine crankshaft (brake horsepower) to the power supplied to the engine (heat content of fuel). By comparing fuel consumption to engine power output, you can find engine efficiency.

If all the heat energy in the fuel were converted into useful power, the engine would be 100% efficient. Modern piston engines are only about 20% efficient.

Figure 16-10 illustrates how the heat energy of the fuel is used by a piston engine. About 70% of the fuel's energy is used by the cooling and exhaust systems. This leaves a small portion to drive the pistons.

Volumetric Efficiency

Volumetric efficiency is the ratio of air drawn into the cylinder and the maximum possible amount of air that could enter the cylinder. It is an indication of how well an engine can "breathe" on its intake stroke.

If volumetric efficiency was 100%, the cylinder would completely fill with air on the intake stroke. Engines are capable of only 80–90% volumetric efficiency. Restrictions in the ports and around the valves limit airflow.

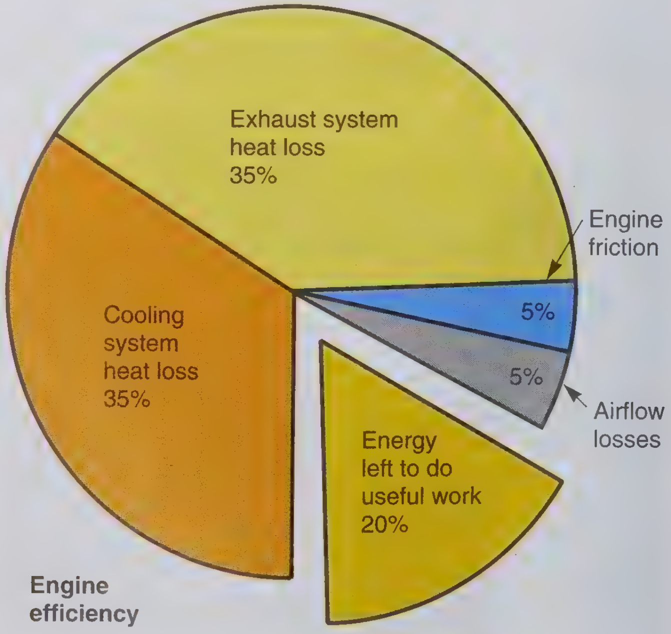

Figure 16-10. Pie chart shows how fuel's heat energy is used by a piston engine. Note that most of the heat energy is wasted. Aerodynamic body designs increase vehicle fuel economy. The vehicle must pass through air, which is actually a fluid by nature. The aerodynamic design reduces drag. (Buick)

High volumetric efficiency increases engine power because more fuel and air can be burned in the combustion chambers. The formula for volumetric efficiency is:

$$\text{volumetric efficiency} = \frac{\text{actual volume of air taken into cylinder}}{\text{volume of cylinder}}$$

Mechanical Efficiency

Mechanical efficiency compares brake horsepower and indicated horsepower. It is a measurement of mechanical friction. Indicated horsepower is the theoretical power produced by combustion. Brake horsepower is the actual power at the engine crankshaft. The difference between the two is due to friction losses.

Mechanical efficiency of 70–80% is normal. This means that 20–30% of the engine's power is lost to friction (frictional hp loss). The friction between the piston rings and cylinder walls accounts for most of this loss.

Thermal Efficiency

Thermal efficiency is found by comparing the horsepower output to the amount of fuel burned. It indicates how well an engine uses the fuel's heat energy. Thermal efficiency measures the amount of heat energy converted into crankshaft rotation.

Generally, engine thermal efficiency is 20–30%. The rest of the heat energy is absorbed by the metal parts of the engine or blown out the exhaust.

Industry Trend

Vehicle design has been greatly refined during the last few years. Sports cars like the Corvette and the Dodge Viper produce over 400 horsepower while producing far less pollution than their counterparts of past. High-performance, "race-bred parts" are found in every major system of today's sports cars.

Summary

- Engine size is determined by cylinder diameter, amount of piston travel on each stroke, and number of cylinders.
- Cylinder bore is the diameter of the engine cylinder.
- Piston stroke is the distance the piston moves from TDC to BDC.
- Piston displacement is the volume the piston displaces (moves) from BDC to TDC.
- Engine displacement or engine size equals piston displacement times the number of engine cylinders.
- Force is a pushing or pulling action.
- Work is done when force causes movement.
- Power is the rate or speed at which work is done.
- Engine compression ratio compares cylinder volumes with the piston at TDC and BDC.
- Compression pressure is the amount of pressure produced in the engine cylinder on the compression stroke.
- Torque is a turning or twisting force.
- Engine torque is a rating of the turning force at the engine crankshaft.
- Horsepower (hp) is a measure of an engine's ability to perform work.
- Brake horsepower (bhp) measures the usable power at the engine crankshaft.
- An engine dynamometer (dyno) is used to measure the brake horsepower of modern car engines.
- A chassis dynamometer measures the horsepower delivered to the drive wheels.
- Engine efficiency is the ratio of power produced by the engine (brake horsepower) and the power supplied to the engine (heat content of fuel).
- Volumetric efficiency is the ratio of actual air drawn into the cylinder and the maximum possible amount of air that could enter the cylinder.
- Mechanical efficiency compares brake and indicated horsepowers. It is a measurement of mechanical friction.
- Thermal efficiency is heat efficiency found by comparing fuel burned and horsepower output.

Review Questions—Chapter 16

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What three factors determine engine size?
2. Cylinder bore is measured across the cylinder, parallel with the top of the block. True or False?
3. Piston stroke is the distance the piston moves during a complete four-stroke cycle. True or False?
4. _____ _____ is the volume the piston moves from BDC to TDC.
5. If an engine has a bore of 3.5″ and a stroke of 3″, what is the piston displacement?
6. Define the term "engine displacement."
7. Explain the difference between force, work, and power.
8. When a gasoline engine's piston is at BDC, the cylinder volume is 45 cu. in. When the piston slides to TDC, the cylinder volume is 9 cu. in. What is the compression ratio for this engine?
   (A) 8:1.
   (B) 5:1.
   (C) 7:1.
   (D) 9:1.
9. Which of the following would *not* be a compression ratio for a car engine?
   (A) 2:1.
   (B) 8:1.
   (C) 17:1.
   (D) 20:1.
10. A gasoline engine may produce a compression pressure of _____ to _____ psi (_____ to _____ kPa).
11. A diesel engine can produce a compression pressure of about _____ to _____ psi (_____ to _____ kPa).
12. What is engine torque?
13. Explain the term "horsepower."
14. The ratio of actual air drawn into an engine to the maximum possible air that could enter the engine is called _____ _____.
15. A piston engine's thermal efficiency is approximately _____.
    (A) 80-100%
    (B) 70-80%
    (C) 40-50%
    (D) 20-30%

ASE-Type Questions

1. Engine size is determined by:
   (A) cylinder diameter.
   (B) number of cylinders.
   (C) piston travel per stroke.
   (D) All of the above.
2. The distance a piston moves from TDC to BDC is called:
   (A) piston taper.
   (B) piston stroke.
   (C) piston clearance.
   (D) piston displacement.
3. Piston displacement times the number of engine cylinders equals:
   (A) engine size.
   (B) cylinder bore.
   (C) engine torque.
   (D) compression ratio.
4. Work can be measured in:
   (A) watts.
   (B) joules.
   (C) kilograms.
   (D) kilopascals.
5. Modern gasoline engines have a compression ratio of about:
   (A) 8 or 9:1.
   (B) 12 or 13:1.
   (C) 15 or 16:1.
   (D) 20 or 21:1.
6. Compression pressure is measured in:
   (A) kilopascals.
   (B) pounds per square inch.
   (C) Both A and B.
   (D) Neither A nor B.
7. Diesel engines have compression pressure of about:
   (A) 130 to 180 psi.
   (B) 250 to 400 psi.
   (C) 425 to 500 psi.
   (D) 510 to 525 psi.

8. One horsepower equals:
    - (A) *28,000 kW of work per minute.*
    - (B) *25,000 ft lb of work per hour.*
    - (C) *30,000 in lb of work per second.*
    - (D) *33,000 ft lb of work per minute.*
9. Which of the following is used to measure brake hp of an engine?
    - (A) *Brake tachometer.*
    - (B) *Compression gauge.*
    - (C) *Engine dynamometer.*
    - (D) *Chassis dynamometer.*
10. Which abbreviation indicates the amount of power or pressure formed in engine combustion chambers?
    - (A) *ihp.*
    - (B) *fhp.*
    - (C) *ghp.*
    - (D) *thp.*

Activities—Chapter 16

1. Use a compression gauge to measure the compression of each cylinder of an engine. Check your findings against the specifications for that engine. Are all the readings "in spec," or do one or more cylinders read high or low?
2. Convert your compression readings from pounds per square inch to kilopascals, or vice versa. Multiply psi readings by 6.895 to find kPa; divide kPa readings by 6.895 to find psi.

Section 3

Computer Systems

17. Computer System Fundamentals
18. On-Board Diagnostics and Scan Tools
19. Computer System Service

Today's vehicles are as much electronic as they are mechanical. Computers control and monitor every major system in a modern car or light truck. It is virtually impossible to work on almost any vehicle without a basic knowledge of computers.

Section 3 details the theory and operation of computer systems, explains how to use a scan tool to find troubles in computerized systems, and describes the use of pinpoint tests to verify the basic electrical/electronic faults indicated by the scan tool.

This important section will prepare you for almost every other chapter in this textbook. Study it carefully! This section will also help you pass several ASE certification tests requiring a knowledge of computers, sensors, actuators, scan tools, and related topics, including Test A6, *Electrical/Electronic Systems, and Test A8, Engine Performance*.

17

Computer System Fundamentals

After studying this chapter, you will be able to:

- Compare computer systems to the human body's nervous system.
- Describe the input, processing, and output sections of a basic computer system.
- Explain input sensor and output device classifications and operation.
- Summarize computer system signal classifications.
- Sketch a block diagram for a computer system.
- Summarize where computers, control modules, sensors, and actuators are typically located.
- Summarize the flow of data through a computer.
- Explain how a computer uses sensor inputs to determine correct outputs.
- Correctly answer ASE certification test questions that require a knowledge of automotive computer system fundamentals.

A ***computer*** is a complex electronic device that will produce programmed electrical output signals after receiving specific electrical input signals. Computers now monitor and control all major systems of a modern vehicle. In fact, today's cars and trucks are as much electronic as they are mechanical.

It is almost impossible to work on almost any automotive system without having a basic knowledge of vehicle computers. In the past, automotive systems (ignition, cooling, emissions, and fuel, for example) worked independent of each other. Today, automotive systems work together in a tightly integrated package and share many of the same sensors and actuators. This makes it important for you to fully understand how automotive computer systems operate.

This chapter will give you a basic picture of automotive computer systems. It will also provide you with the background information needed to understand the material presented in the next two chapters—*On-board Diagnostics and Scan Tools* and *Computer System Service.* It will also help prepare you for almost all the following chapters in this book.

Note!
Before starting this chapter, you may want to review Chapter 1, *The Automobile,* and Chapter 8, *Basic Electricity and Electronics.*

Cybernetics

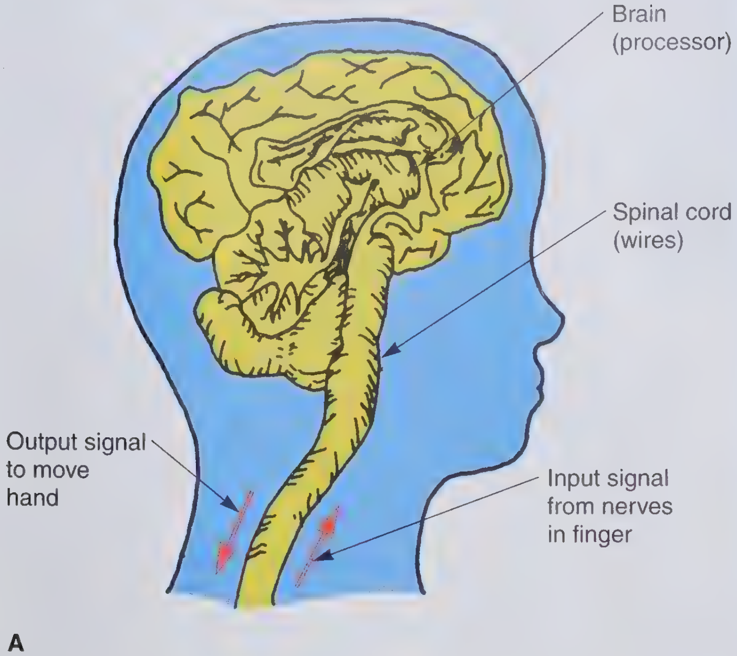
The term ***cybernetics*** is often used to refer to the study of how electrical-mechanical devices can duplicate the action of the human body. Comparing the human body to a computer system is an easy way to explain this subject. Just as your brain communicates with and controls parts of your body, an automotive computer system can communicate with and control parts of a vehicle. See **Figure 17-1.**

The Nervous System (Computer Input)

The human nervous system uses chemical-electrical signals to control the body. If you touch a sharp needle, nerve cells in your finger "fire" and send a signal through a strand of nerve cells in your hand, up your arm, and into your brain. The strand of nerve cells forms a "wire" that connects your finger and brain. The nerve cells in the tip of your finger are comparable to a sensor, or input device, in a computer system.

The Brain (Computer Processing)

The brain uses billions of cells interconnected by linking cells called neurons. Each neuron chemically-electrically connects tens of thousands of neighboring cells. When the brain "thinks," minute electrical impulses



Computer system input		Human nervous system
Knock sensor input	⟷	Hearing input
Oxygen sensor input	⟷	Smell input
Light dimming photo cell input	⟷	Sight input
Pressure sensor input	⟷	Touch input
Low oil level sensor input	⟷	Taste input
Solenoid, relay, or servo motor output	⟷	Muscle movement output
Dash graphic display output	⟷	Talk, write, draw output
Memory and processor IC circuits in computer	⟷	Brain's memory and thought

B

Figure 17-1. A—Cybernetics compares the human body to a computer system. B—Study this chart comparing the human nervous system and an automotive computer system.

travel from neuron to neuron. One simple thought might involve electrical impulses between hundreds of thousands of cells in a specific pattern. This is not unlike the electrical action inside the circuits of a computer.

The brain is comparable to a super powerful computer. It can process the inputs from the nervous system and determine what actions should be taken.

In the preceding example, the chemical-electrical signal of a sharp needle prick would tell your brain, "my finger is being injured." Your brain would then take corrective action to protect your finger.

The brain makes decisions much like computers produce logical outputs. The cells in the brain can be either chemically-electrically charged (on) or not be charged (off). By connecting all the brain cells, the brain can decide what to do in each situation.

The Reflex Action (Computer Output)

The needle prick signal activates specific brain cells, and a reflex output is produced. The brain sends a signal back into your arm. This chemical-electrical output signal stimulates the muscles in your arm to pull back, protecting your finger from the sharp object. The reflex action of your muscles is similar to the action of an actuator, or output device, in a car's computer system.

Computer Advantages

There are several reasons that computers are being used in modern vehicles. Computers provide several advantages.

- Computer systems can compensate for mechanical wear. Also, they do not have as many mechanical parts to wear and go out of calibration.
- Computers are very fast and can alter outputs in milliseconds (thousandths of a second). This lets a computer alter outputs almost instantly as inputs and operating conditions change.
- Computers reduce fuel consumption and lower emissions by precisely metering fuel into the engine. The computer "sniffs" the exhaust gases to find out if too much or too little fuel is entering the engine.
- Computers can increase engine power by accurately controlling ignition timing, fuel injection, emission control system operation, etc.

- Computers reduce vehicle weight because they are much lighter than mechanical control mechanisms.
- Most computers have on-board diagnostics that can detect and record system problems. The on-board computer can produce and store an output code that tells the technician where a fault might be located.
- Computers can increase driver convenience by better control of the passenger compartment environment and dash displays.
- Computers can improve passenger safety by controlling the anti-lock brakes, air bags, suspension, and other systems.
- Computers can compensate for component wear and failure to keep the car driveable.

Digital Electronics

Digital electronics is a field of study dealing with the ways a computer uses on-off signals to produce "artificial intelligence."

A computer analyzes input signals from sensors. It has memory in which fixed and semi-fixed data is stored. The computer can make logical choices on how to control specific outputs by comparing the input signals to the data stored in memory.

Binary Numbering System

The ***binary numbering system*** uses only two numbers, zero and one, and is the key to how computers operate. The numbers zero (0) and one (1) can be arranged in different sequences to represent other numbers, letters, words, a computer input, a computer output, or a condition.

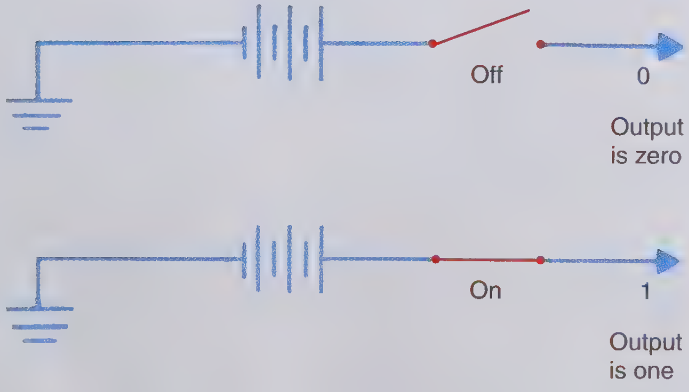


Figure 17-2. Since electronic components can be either on or off, the binary numbering system is ideal for digital logic and computer circuits. The binary system has only two numbers, zero and one, which represent *off* and *on* conditions.

To use the binary system, a computer turns switches (transistors, for example) either on or off. *Off* would represent a zero (0) and *on* would represent one (1) in the binary system, **Figure 17-2.**

Note that a 0011 in binary would equal a three (3) in the base 10 decimal system. A 0110 in binary would equal a six (6) in the base 10 system, **Figure 17-3.**

In binary language, a zero or a one is called a *bit*. A pattern of four bits is a *nibble*. A pattern of eight bits (zeros or ones) is called a *byte*, (pronounced "bite."). One or more bytes are referred to as a *word*. You are more likely to hear this terminology when you work with home or personal computers. Look at **Figure 17-4.**

Gating Circuits

A ***gate*** is an electronic circuit that produces a specific output voltage for given input voltages. Just as a diode will pass current when forward biased (output lead would have voltage representing one) and stop current when

Decimal number	Binary number code 8 4 2 1	Binary to decimal conversion
0	0 0 0 0	= 0 + 0 + 0 + 0 = 0
1	0 0 0 1	= 0 + 0 + 0 + 1 = 1
2	0 0 1 0	= 0 + 0 + 2 + 0 = 2
3	0 0 1 1	= 0 + 0 + 2 + 1 = 3
4	0 1 0 0	= 0 + 4 + 0 + 0 = 4
5	0 1 0 1	= 0 + 4 + 0 + 1 = 5
6	0 1 1 0	= 0 + 4 + 2 + 0 = 6
7	0 1 1 1	= 0 + 4 + 2 + 1 = 7
8	1 0 0 0	= 8 + 0 + 0 + 0 = 8

Figure 17-3. Binary numbers can be converted into decimal (base ten) numbers. Note how the right-hand binary number equals one and the left-hand number equals eight.

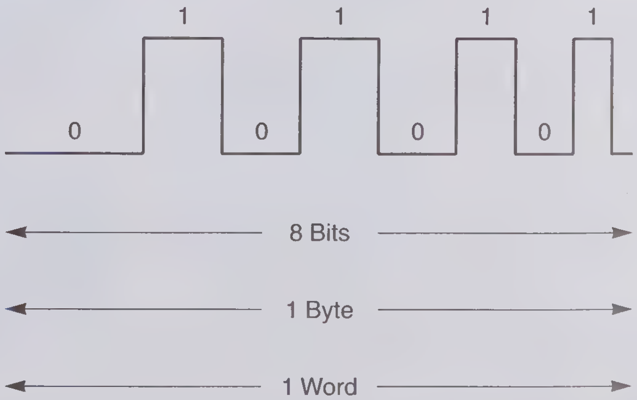

Figure 17-4. Each *one* (voltage on) or *zero* (voltage off) signal equals a bit of computer data. Eight bits equal a byte, or a word.

reverse biased (output would be zero or no voltage), gates have *programmed* (previously known) outputs. Shown in **Figure 17-5,** the most common computer gates are:

- *NOT gate*—also called an *inverter gate*, this gate will reverse its input. If the input has voltage applied (1), the output terminals will *not* have voltage (0) or vice versa. A NOT gate can be used to make other gates.
- *AND gate*—an AND gate requires voltage (1) at *both inputs* to produce a voltage (1) at the output. If pins A and B are *both one* (1), the output will be *1*. If only pin A or pin B is one, the output will be 0.
- *NAND gate*—is an inverted AND gate. Its output will be opposite that of an AND gate. Note the small circle or dot on the output lead of the gate. The small circle represents an inverter.
- *OR gate*—will produce an output (one or on) if *either* input is energized (1). A or B input voltage (1) will result in voltage (1) at the output lead.
- *NOR gate*—is an inverted OR gate. Note the small circle that represents an inverter. The output is inverted to produce an output opposite that of an OR gate.

1	1	0

E—NOR gate is an inverted OR gate; no input voltage will produce an output voltage.

Figure 17-5. Study the basic types of computer gates. Truth tables on the right show what the output of each gate will be with different inputs.

Truth Tables

A truth table is a chart that shows what the output of a gate will be with different inputs. Look at the truth table for an OR gate shown in **Figure 17-6.** Note that if two switches are wired in parallel, either switch A or switch B (OR gate) will turn the light *on* (output 1). The output will be *on* (1) with A or B or both energized. Only when neither input is *on* will the output be *off* (0). A truth table graphically shows how a gate functions.

Gates are often called *logic devices* because they make logical decisions (outputs) based on specific inputs

(facts). If an AND gate was compared with two switches wired in series, both switches (A and B) must be *on* to activate the starter motor, **Figure 17-7.** Compare these circuits to the action of the gates and the truth tables.

Using Gates

Logic gates can be connected together to form super-complex circuits. Millions of gates can be interconnected to produce thousands of preprogrammed outputs (decisions) from numerous inputs (facts). This is how a computer works, or thinks. Its circuitry and software are designed to make the correct output signals based on various input signals. In this way, a computer knows what to do to keep the vehicle operating efficiently with many different variables.

Integrated Circuits

Discussed briefly in Chapter 8, an ***integrated circuit (IC)*** is an electronic circuit that has been reduced in size and etched on the surface of a tiny semiconductor chip, **Figure 17-8. Figure 17-9** shows the basic construction of an integrated circuit. Note how different semiconductor substances are deposited on the silicone chip and then etched to produce resistors, diodes, and transistors.

Metal conductors on the top of the chip connect these various electronic components to form the circuit. Wire leads allow for input and output connections to and from the IC chip.

Computer Signals

A ***computer signal*** is a voltage variation over short periods of time. It is a specific arrangement of pulses or

The same principle, only with thousands of gates and dozens of inputs and outputs, is used inside an automotive computer.

waves used to carry data, or information. You must be familiar with computer signals to understand the operation and service computer systems.

Computer signals can be digital or analog. **Figure 17-10** compares analog and digital signals.

As discussed earlier, ***digital signals*** are on-off signals, like those produced by a rapidly flipping switch. An example of a sensor providing a digital signal is a Hall effect–type crankshaft position sensor, which shows engine RPM. Voltage output goes from maximum to

Analog signal

Figure 17-11. These are the two basic signals found in computer system circuits. Voltage is shown vertically and time is shown horizontally. An oscilloscope can be used to measure computer signals. A—Digital signal is an on-off voltage change shown by a vertical line going between zero and the applied voltage. When at zero volts, the signal would be off. When at 5 volts, for this example, the signal would be on. B—An analog signal progressively changes voltage, as shown by the smooth waveform curve. Many sensors produce analog signals.

minimum. A digital signal basically produces a square wave. See **Figure 17-11A.**

An ***analog signal*** gradually changes in strength. For example, a sensor's internal resistance (and resulting current or voltage signal) may smoothly increase or decrease with changes in temperature, pressure, or part position. An analog signal will produce a curved wave or an irregular wave. See **Figure 17-11B.**

Computer signals can be measured with an oscilloscope (introduced in Chapter 4 and detailed in Chapter 46).

If a scope is connected to a sensor that generates a signal voltage, a trace of the signal, or ***waveform,*** can be viewed on the scope. **Figure 17-12** shows how a scope will display a waveform for a magnetic speed sensor. There are many types of electrical waveforms within the analog-digital categories, **Figure 17-13.** A few of the most common include:

- ***AC sine wave***—a curving signal that smoothly fluctuates above and below zero volts. The electricity in your home or inside an alternator would produce an ac sine wave.

- ***DC sine wave***—a curving, fluctuating signal that stays at or above zero volts.
- ***DC square wave***—digital, on-off signal that stays at or above zero volts.
- ***DC ramp wave***—moves steadily up from zero and then switches off almost instantly.
- ***Pulse wave***—signal that rises progressively from zero and then almost instantly returns to zero.
- ***Complex sine wave***—signal voltage that moves up and down erratically but gradually.
- ***Voice wave***—an irregular wave that corresponds to the frequency of the human voice.
- ***DC noise wave***—a straight line (dc) with some voltage′ fluctuations (noise). Noise is usually unwanted voltage spikes in a circuit and is caused by induced voltage from an outside source.

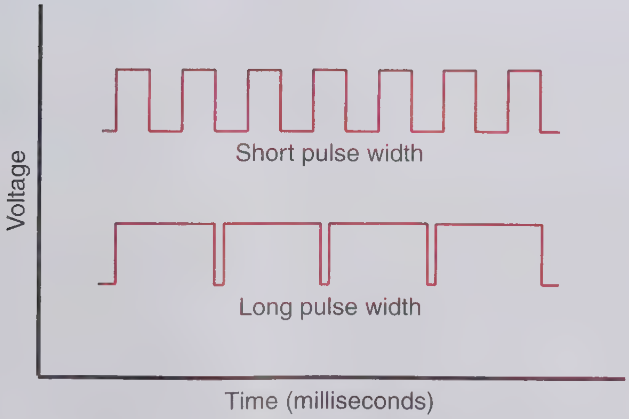
Computer Signal Terminology

There are several terms used to describe computer signals. Signal frequency, or ***pulse width,*** generally refers to how fast a voltage signal changes over time. The signal frequency from a sensor might be measured in milliseconds, or thousandths of a second.

A high-frequency signal would be very short (narrow), or have a short pulse width. A low-frequency signal would be longer (wider), or would have a long pulse width, **Figure 17-14.**

Signal amplitude refers to how much voltage is present in the wave. A *high-amplitude signal* would have more voltage than a *low-amplitude signal.* Most automotive computer systems use a signal amplitude of about 3–5 volts. See **Figure 17-15.**

Duty cycle is the percentage of *on* time compared to total cycle time. Along with pulse width, it can be used to measure a signal or pulse as a percentage. For example, if a solenoid is sent a 50% duty cycle, it will be turned on half the time and off half the time, **Figure 17-16.**



Voltage
Short pulse width
Long pulse width
Time (milliseconds)

Figure 17-14. Signal frequency can also be denoted as pulse width. A short pulse width, or high-frequency signal, is not very wide. A long pulse width, or low-frequency signal, would appear wider on a scope.

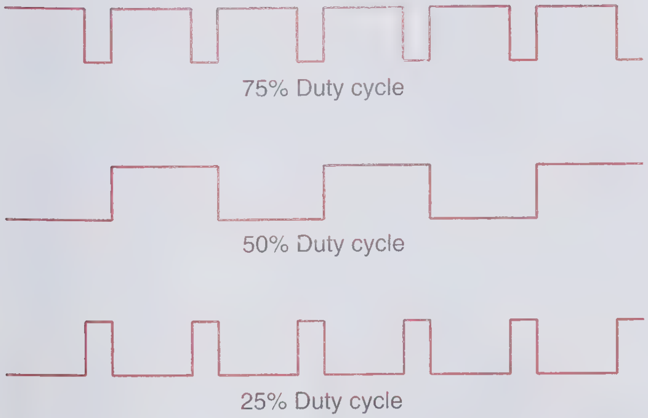
Computer System Operation

There are three stages of computer system operation:

- ***Input***—vehicle sensors convert a condition into an electrical signal that can be used by the computer.
- ***Processing*** and ***Storage***—the computer compares sensor inputs to data and operating parameters in its memory to determine what action should be



75% Duty cycle
50% Duty cycle

Figure 17-16. Duty cycle is another way of denoting a circuit's on-time. It is expressed as a percentage.

taken to control the vehicle's systems. The computer can remember programming, as well as store trouble codes in its memory chips.

- ***Output***—the computer produces an electrical output signal so actuators can perform physical actions to alter component operation.

Figure 17-17 shows the stages of computer system operation. You must be able to visualize this flow of electrical-electronic data and the changes in operation that result.

Computer System Block Diagram

A ***computer system block diagram*** is a simple service manual drawing that shows how the sensors, the actuators, and the computer interact. It uses basic squares or rectangles to represent components and lines to represent wires. A computer block diagram is handy when trying to find out what types of sensors are used and what conditions are controlled by a specific computer system. A block diagram for one computer control system is shown in **Figure 17-18.** Study the various inputs and outputs.

Sensors

Most ***vehicle sensors,*** or transducers, change a physical condition into an electrical signal. ***Transduce*** means to change from one form to another. Just as our eyes, ears, nose, fingers, etc., can sense conditions, vehicle sensors can detect the operating conditions of a car or truck.

The computers use the voltage signals from sensors to control the actuators.

Sensor Locations

Sensors can be found almost anywhere on a vehicle. Many are mounted on the engine, **Figure 17-19.** Others can be located on or in the transmission or transaxle, in the exhaust system, on the wheel hubs, on and in the fuel tank, on the suspension, or even in the trunk (impact sensor). If in doubt, refer to the service manual for the specific vehicle to find sensor types and locations.

Sensor Classifications

An automobile uses several types of sensors to provide electrical data to the computer. There are dozens of specific names for vehicle sensors. However, they can all be classified into two general categories: active sensors and passive sensors.

An ***active sensor*** produces its own voltage signal internally. This very weak signal is fed back to the computer for analysis. Look at **Figure 17-20A.** ***Shielded wire,*** which has a flexible metal tube around the conductor to block induced voltage and interference, is often used with active sensors.

A ***passive sensor*** is a variable resistance sensor. Voltage is fed to the sensor from the computer. The passive sensor's resistance varies with changes in a condition (temperature, pressure, motion, etc.). The computer can detect the resulting change in voltage caused by the change in resistance. See **Figure 17-20B.** Within these two categories are several sensor types:

- ***Variable resistor sensor***—changes its internal resistance with a change in a condition; its ohms value may change with temperature, pressure, etc. It is an analog sensor. Examples of variable resistance sensors are throttle position and temperature sensors. A ***potentiometer*** is a variation of a variable resistor sensor. It has three external

Figure 17-21. These are the basic classifications of input sensors. Each sensor feeds a different type of signal to the computer.

- ***Switching sensor***—opens or closes the sensor circuit to provide an electrical signal for the computer. Transmission pressure switches are examples of this type of sensor. A switching sensor can detect almost any condition and produces a digital signal, **Figure 17-21.**
- ***Magnetic sensor***—uses part movement and induced current to produce a signal for the computer. This type of sensor is commonly used to monitor speed (vehicle speed sensor) or part rotation. It usually produces an analog signal. Magnetic sensors are also referred to as permanent magnet (PM) generators.
- ***Hall-effect sensor***—uses a special semiconductor chip to sense part movement and speed, **Figure 17-22.** It produces a digital signal. These sensors are used as crankshaft and camshaft position sensors, as well as pickup devices in some electronic ignition distributors.

No current flow is indicated by the meter. B—When a magnetic field acts on the element, some current is diverted into the sensor, as indicated by the meter. This signal is used by the computer to detect part rotation.

- ***Optical sensor***—uses light-emitting diodes and photo diodes to produce a digital signal. Optical sensors may be used to sense part rotation and speed. See **Figure 17-23.** These sensors are used in some distributors and as speed sensors mounted outside the speedometer.
- ***Piezoelectric sensor***—generates voltage from a physical shock or motion. It is sometimes used to listen to a condition, such as engine knocking (knock sensor), **Figure 17-24.**
- ***Solar sensor***—converts sunlight directly into an electrical signal. It is made of a semiconductor material that converts photons (light energy) into direct current, **Figure 17-25.**
- ***Direction sensor***—detects the polarity of a moving magnet. This is a variation of a magnetic

sensor. Unlike a magnetic sensor, it can signal which direction a part is rotating. It is used in some computer-controlled steering systems, **Figure 17-26.**

Reference Voltage

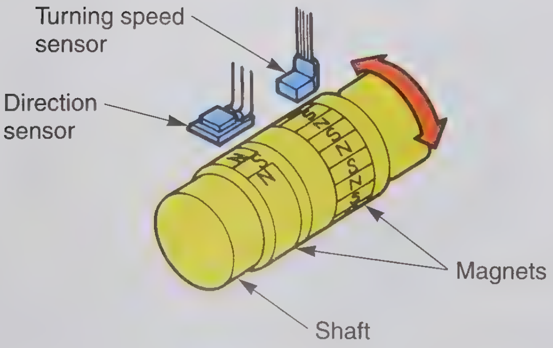
Reference voltage, sometimes abbreviated ***Vref,*** is the base voltage used to carry a computer signal. The computer sends a reference voltage to a passive sensor so that a signal can be fed back for processing. A reference voltage is needed so that a change in sensor resistance can be read by the computer as a change in current and voltage, **Figure 17-27.**

The reference voltage is typically around 5 volts. The computer steps down battery voltage so that a smooth, constant supply of dc voltage is fed to the passive sensors. The sensor alters the reference voltage by changing its internal resistance. This change in reference voltage is interpreted by the computer as a change in condition or state.

Sensor Types

The most common sensors used in late-model vehicles include the following:

- ***Intake air temperature (IAT) sensor***—measures the temperature of intake air as it enters the intake manifold. The IAT is also called a manifold air temperature (MAT) or an inlet air temperature sensor.
- ***Engine coolant temperature (ECT) sensor***—measures the temperature of engine coolant. In most cases, it is simply referred to as a coolant temperature sensor.



Turning speed sensor
Direction sensor

Supply voltage to computer

Figure 17-27. A computer power supply or voltage regulator sends voltage to each passive sensor. Most passive sensors modify the voltage to produce an analog signal. If weak, the analog signal is first amplified, or increased in strength. A conditioner, or interface, converts the analog signal into a digital signal. The digital signal can then be processed by the computer.

- ***Oxygen (O_2) sensors***—measure the amount of oxygen in the engine's exhaust gases before and after the catalytic converter. Most newer sensors contain heaters and are referred to as heated oxygen sensors (HO_2S).
- ***Manifold absolute pressure (MAP) sensor***—measures outside air pressure in relation to vacuum inside the engine intake manifold.
- ***Barometric pressure (BARO) sensor***—measures the outside air pressure around the engine. It is combined with the MAP sensor on most newer vehicles.
- ***Throttle position sensor (TPS)***—measures the opening angle of the throttle valves to detect how much power is requested by the driver.
- ***Engine speed sensor***—measures engine rpm for ignition system operation. May be located in the distributor or next to the crankshaft or camshaft.
- ***Crankshaft position sensor***—measures crankshaft position, rotation, and speed.
- ***Camshaft sensor***—checks the engine camshaft position and rotation.
- ***Mass airflow (MAF) sensor***—measures the amount of intake air flowing into the engine. It is often referred to as an airflow sensor or an airflow meter.

- ***Knock sensor (KS)*—**piezoelectric sensor that detects engine pinging, preignition, or detonation so the computer can retard ignition timing or reduce turbocharger boost pressure.
- ***Transaxle/transmission sensor*—**checks transaxle or transmission gear selection. It is usually a part of the neutral safety switch.
- ***Brake switch*—**detects brake pedal application.
- ***Wheel speed sensor*—**measures wheel rotational speed for anti-lock brake and traction control systems.
- ***Oil level sensor*—**measures the amount of oil in the engine oil pan.
- ***EGR sensor*—**measures the position of the exhaust gas recirculation valve pintle.
- ***Impact sensors*—**detect a collision to shut off the fuel pump or the engine. Another type of impact sensor is used to deploy the air bag system.
- ***Vehicle speed sensor*—**measures the vehicle's road speed so the computer can adjust fuel, ignition, transmission, suspension, and other system operations. It is located in the transmission/transaxle housing.
- ***Fuel tank pressure sensor*—**measures fuel tank and system pressure as part of some evaporative emission control systems. It is similar in construction and operation to a MAP sensor.
- ***Battery temperature sensor*—**monitors battery temperature so the computer can adjust vehicle operation to affect charging system output as needed.

Older cars use none or just a few of these sensors. Newer cars might use these and many other sensors.

Circuit Sensing

Circuit sensing involves using the computer itself instead of dedicated sensors to monitor component and circuit operation. The computer monitors current flow through various components and circuits. For example, some circuit sensing systems can monitor fuel injector operation (injector coil winding current), ignition coil action (current through ignition coil windings), and computer operation (current through computer circuits). The windings and the wires in the circuits serve as the sensors.

Computers

The term computer is a general term that refers to any electronic circuit configuration that can use multiple inputs to find outputs. Automobile manufacturers use many names for their computers, including:

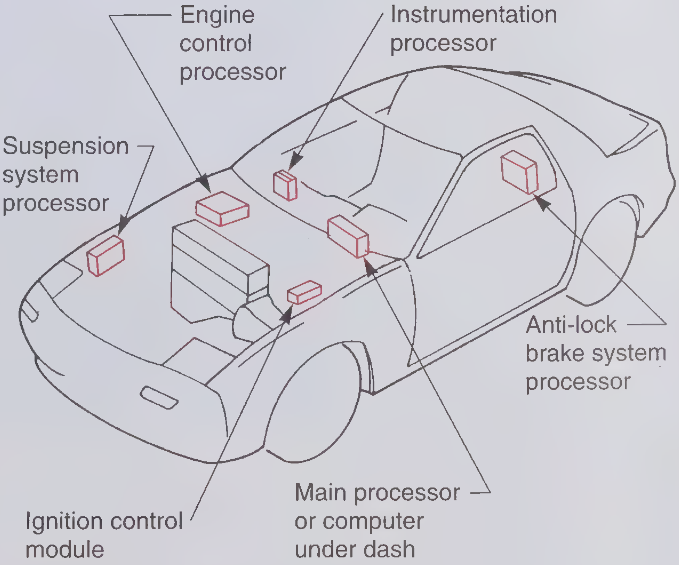
- Central processing unit (CPU).
- Electronic control unit (ECU).
- Electronic control module (ECM).
- Engine control module (ECM).
- Electronic control assembly (ECA).
- Powertrain control module (PCM).
- Vehicle control module (VCM).
- Microprocessor.
- Logic module.

Keep these names in mind when reading service manuals. To prevent confusion, this textbook will use the terms *computer* and *control module* when referring to computers in general. When discussing a computer used to control one or more systems, the text will use the terms recommended by the Society of Automotive Engineers (J1930). Additionally, the term "module" will be used for an electronic circuit used to amplify and/or modify a single signal or control a single system, such as the module used to control the operation of the anti-lock brake (ABS) system.

Computer Types

Several types of computers can be used in a car, **Figure 17-28.** The number and types of computers will vary with the manufacturer. The most common types are:

- ***Vehicle control module*—**large, powerful computer that processes data from sensors and other,



Engine control processor
Instrumentation processor
Suspension system processor
Anti-lock brake system processor
Ignition control module
Main processor or computer under dash

Figure 17-28. One or more computers, or control modules, can be used on the same car. Note the potential locations.

less powerful control units. It coordinates engine, transmission, traction control, and anti-lock brake functions, for example.

- ***Powertrain control module***—powerful computer used to monitor and control the engine, transmission, and other systems.
- ***Engine control module***—computer that uses sensor inputs to control engine idle speed, fuel injection, ignition timing, emission control devices, and other operating parameters.
- ***Anti-lock brake module***—small computer that uses wheel speed sensor inputs and other inputs to control anti-lock brake application.
- ***Instrumentation module***—small computer that uses sensor inputs to operate a digital dash display.
- ***Ignition module***—small computer that uses sensor inputs to control ignition timing, spark plug firing, or ignition coil pack operation.
- ***Suspension system module***—small computer that uses vehicle speed, suspension, and steering sensor inputs to control ride stiffness or shock absorber action.
- ***Climate control module***—small computer used to control the operation of the heating, ventilation, and air conditioning systems.
- ***Air bag module***—small computer that controls the vehicle's air bag system. This module also stores power to deploy the air bags in the event that battery power is lost in a collision.
- ***High-power control module***—computer used to control or increase current flow or process output signals from a few sensors and the main computer. It is also called a *power control module*.
- ***Body module***—computer that provides memory and other functions for the radio, driver's information center, electronic compass, trip computer, cellular telephone, etc.

Again, the number and types of computers and modules used will vary with the year, make, and model of vehicle. The trend is to use a main computer to process most of the input data and control most outputs. In conjunction with the main computer, smaller computer modules are used for the brake system, ignition coils, suspension system, instrumentation, etc. Refer to the service manual to find out what types of computers are used on a specific vehicle.

Computer Locations

Automotive computers may be located under the dash on the passenger side of the vehicle, **Figure 17-28.** This protects the delicate circuits and components in the computer from engine heat, vibration, and moisture. However, computers can also be located in the engine compartment, in the trunk, under the seats, etc.

When located in the engine compartment, the computer is closer to most sensors and actuators. Less wiring and fewer connectors are needed to tie the system together. Modules used to operate the anti-lock brakes and other systems are often found in the engine compartment. Engine and powertrain control modules are located under the dash, in the engine compartment, or in another central location. Modules used with specific systems, such as the ignition or air conditioning systems, are close to, in, or under the system components.

Computer Operation

A computer is sometimes nicknamed the "*black box*." This is because it is enclosed in a box-shaped housing, sometimes made of black plastic or metal, and contains circuits that can do complex operations.

This section will summarize the operation of a computer. Even though you will probably never repair a computer, it will be helpful to you as a technician to understand how a computer uses sensor inputs and produces actuator outputs.

Figure 17-29 shows the inside of an automotive computer. It is composed of printed circuit boards,

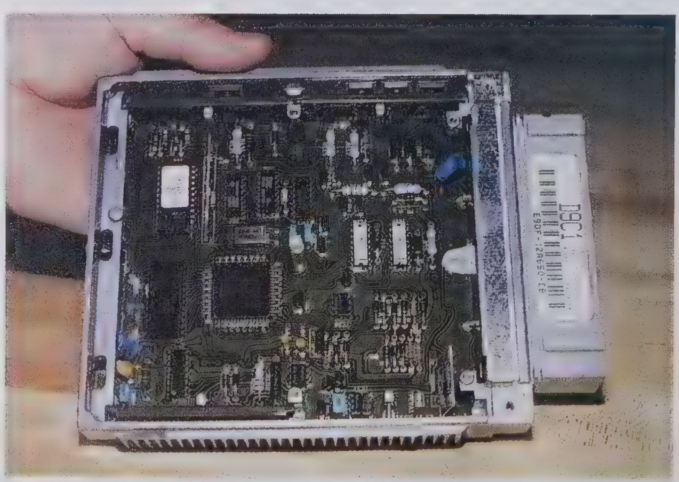


Figure 17-29. This photo shows the inside of a computer. Note that it uses integrated circuits attached to a printed circuit board.

integrated circuits, capacitors, resistors, power transistors, and many other basic electronic components. You learned about these in Chapter 8.

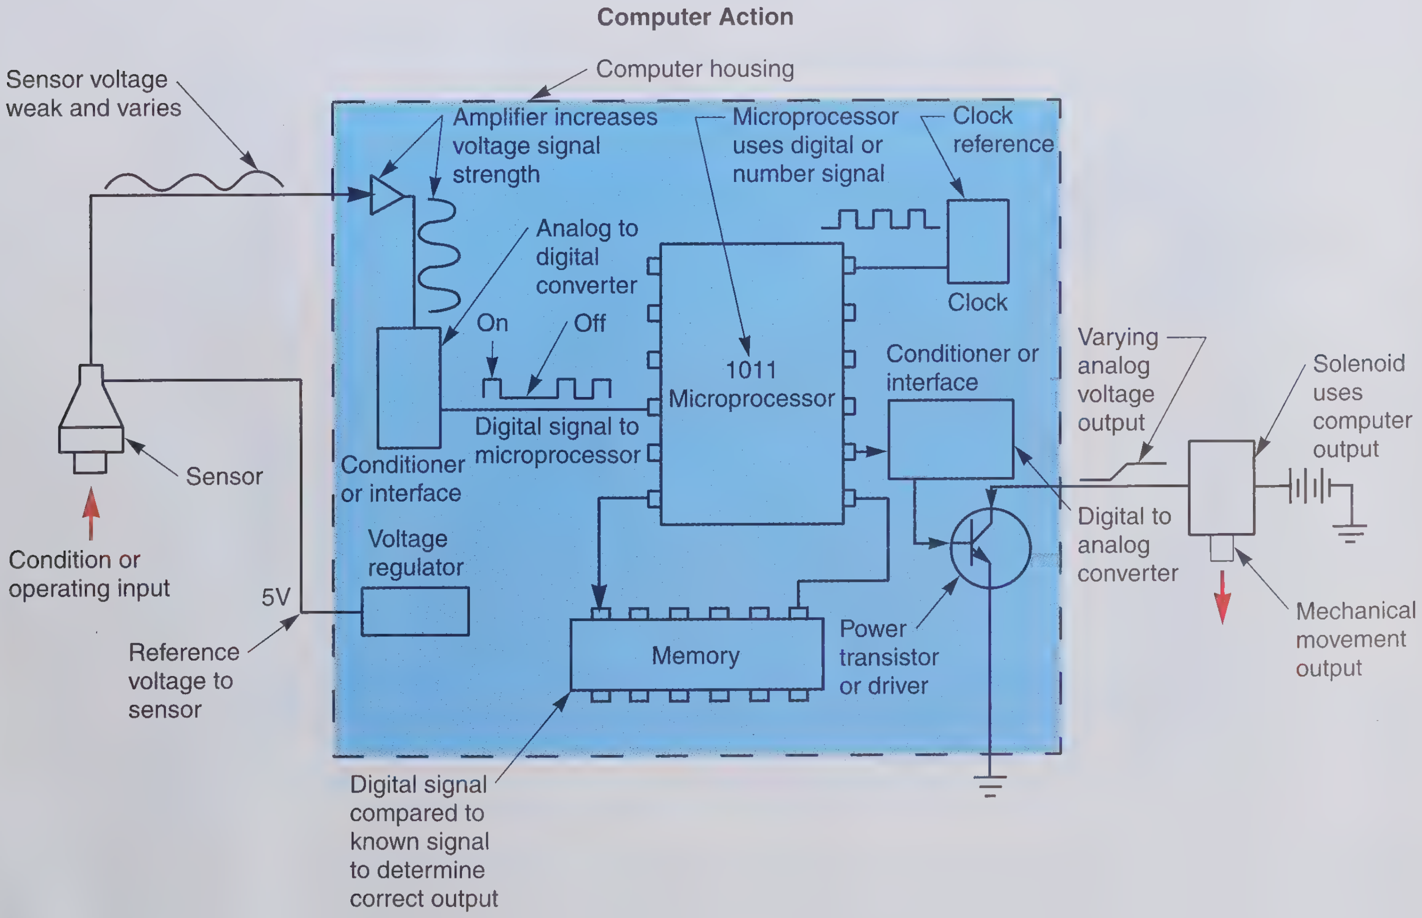
Parts of a Computer

All computers can be divided into sections. Each section has a specific function. Basically, a computer can be divided into eleven parts. These include:

- ***Voltage regulator***—converts battery and other voltages into lower voltages that can be used by the computer and its sensors.
- ***Amplifiers***—increase strength of signals from input devices, **Figure 17-30.**
- ***Conditioners***—alter signals for use by the computer and its actuators.
- ***Buffer***—serves as a temporary storage area for data.
- ***Microprocessor***—integrated circuit that makes decisions or calculations for the computer.
- ***Memory***—integrated circuit that stores data for the microprocessor, **Figure 17-30.**
- ***Clock***—integrated circuit that produces a constant pulse rate to coordinate computer operations.
- ***Output drivers***—power transistors that step up current or provide a ground path to operate actuators or modules.
- ***Circuit board***—fiberboard with flat metal conductors printed on its surface that connects and holds components.
- ***Harness connector***—multipin terminal that attaches to the vehicle's wiring harness.
- ***Computer housing***—metal or plastic enclosure that protects electronic components from induced currents and physical damage.

Computer Voltage Regulator Operation

A *computer voltage regulator* provides a reduced voltage for the electronic components in the computer. This must be a very smooth dc voltage that does not vary and that does not have *spikes* (abrupt changes in voltage).



Computer Action

Figure 17-30. Trace the flow of data through this simplified computer system. Can you explain the purpose of each component?

Computer Amplifier Operation

A *computer amplifier* simply strengthens various signals inside the computer. An amplifier might increase the voltage signal from the oxygen sensor, which is less than one volt. Then, the signal is strong enough to be used by circuits in the computer.

Computer Conditioner Operation

There are two basic types of conditioners in a computer: input conditioners and output conditioners. A conditioner can be called a *converter* or an *interface*. An *input conditioner* alters the input signals from some sensors. It treats incoming data (voltage and current) so it can be utilized by the computer. For example, many sensor signals are analog. The conditioner can convert an analog signal into a comparable digital signal that the computer can understand. An *output conditioner* is needed to change digital signals back into analog signals. The output of the computer must usually be analog to operate the actuators and other control modules.

Both input and output conditioners protect the computer from shorted or grounded circuits. If a sensor, output device, or related circuit is shorted or grounded, the conditioner will not accept the signal and will open the circuit to protect the ECM from damage. This is similar to the operation of a circuit breaker in a shorted electrical circuit.

Buffer

A buffer is a computer device that can serve as a temporary storage area for data. It can also protect internal computer chips from improper data. For example, if data is fed into the computer too quickly, the buffer can hold the data and then feed it into the other devices at a controlled rate. In many cases, the buffer is built into the input conditioners.

Computer Microprocessor Operation

The term *microprocessor* means *small* (micro) *computer* (processor). A microprocessor is a small computer chip or an integrated circuit capable of analyzing data and calculating appropriate outputs. It is the brain of a computer, **Figure 17-31.**

A microprocessor uses the binary number system to make decisions, comparisons, or calculations. Digital pulses from the conditioners are fed into the microprocessor. Since these inputs are off (0) or on (1) voltages, they can be used by the logic gates in the processor.

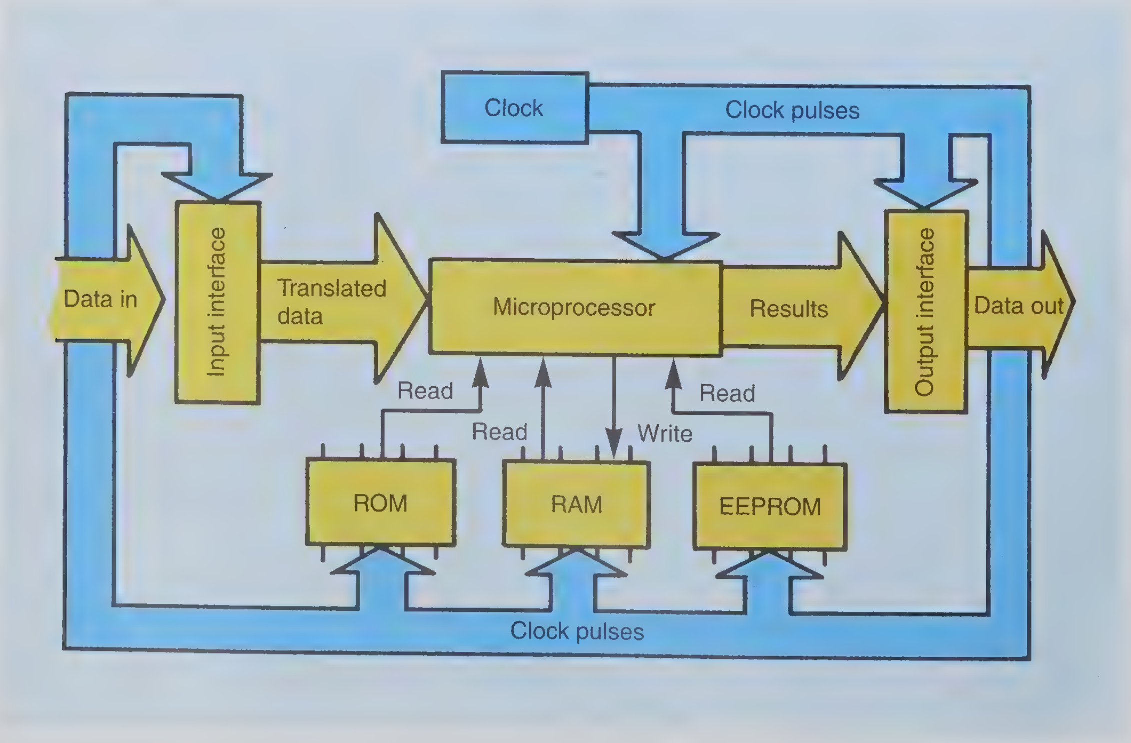

Figure 17-31. Note the flow of data in this block diagram. Data comes in from the sensors. The input interface, or conditioner, changes the analog input data into digital signals. The clock times when data moves from one place to another. The microprocessor compares the input information to permanent memory and writes into temporary memory. The microprocessor decides on the appropriate outputs using logic gates. The results are sent from the microprocessor to the output interface, which changes digital data back into analog signals that can be used by the actuators. (General Motors)

A microprocessor also uses data stored in the computer's memory. It compares input signals to memory data to decide what the outputs should be for maximum efficiency.

Tech Tip!
The computers used on late-model vehicles have more computing power and memory than their predecessors. For example, computers used in late-model vehicles have 16- or 32-bit processors and large read only memory chips. The computers found in older vehicles contain 8-bit processors and smaller memory chips and are not powerful enough to monitor and control present-day vehicle systems.

Computer Memory Operation

Computer memory uses gates that are capable of storing data as voltage charges. The integrated circuits inside the memory chips will hold the data (*on* or *off* charges) until needed by the microprocessor. There are several basic types of computer memories:

- ***Random access memory (RAM)***—is a memory chip used by the computer to store information or data *temporarily.* This data is erased if battery power to the computer is removed.
- ***Read only memory (ROM)***—stores permanent data that cannot be removed from memory. This memory chip contains calibration tables and look-up tables for the general make and model car.
- ***Programmable read only memory (PROM)***—is a memory chip containing permanent data that is more specific than the data stored in ROM. The microprocessor can read from the PROM, but it cannot write to the PROM.

The PROM contains specific information about the vehicle's engine (number of cylinders, valve sizes, compression ratio, fuel system type), transaxle (shift points, gear ratios, etc.), weight, tire size, optional accessories, and any unique features. For example, a car with a manual transaxle will have a different PROM than one with an automatic transaxle.

The PROM is the only part of some computers that is commonly serviced. During computer replacement on some vehicles, the PROM chip can be removed from the old computer and reused in the new computer. PROMs are also replaced to correct a performance or operation problem. The PROM seldom fails, and it is programmed for the specific make and model car. Data is retained in the PROM even when the chip is removed from the computer. The ECMs used on late-model vehicles use a different type of programmable read only memory that is permanently fixed to the circuit board but can be erased and reprogrammed.

- ***Erasable programmable read only memory (EPROM)***—can be changed. However, in most cases, the changes can only be made by the manufacturer using special equipment. This type of memory is also responsible for storing semipermanent data, such as odometer or mileage readings for an electronic dash display.
- ***Electrically erasable programmable read only memory (EEPROM)***—can be altered by the technician in the field. This allows the manufacturer to easily change operating parameters if a performance or driveability problem is discovered.
- ***Flash erasable programmable read only memory (FEPROM)***—is similar to EEPROMs in all respects. FEPROM is simply another name for an EEPROM.

Another type of computer chip found in some computers is known as ***keep alive memory (KAM)***. KAM allows the computer to have an adaptive strategy. An ***adaptive strategy*** is needed as parts wear and components deteriorate. The information stored in KAM allows the computer to maintain normal vehicle performance with abnormal inputs from sensors. It gives the computer the ability to also ignore false inputs to maintain good driveability.

Tech Tip!
Different computer designs will use different memory chips. Also, the names of these chips can vary.

Output Drivers

Output drivers, sometimes referred to as *quad drivers* or *power transistors,* control current flow through the actuators. When energized by the computer, the drivers ground the actuator circuits. The actuators can then produce movement, such as turning the electric cooling fans.

Processor-Memory Bus

The processor-memory bus is the pathway by which sections of a computer communicate, or exchange data. When the computer is operating, data rapidly shuffles between the memory chips and the microprocessor chip. The microprocessor chip controls this flow of data. Sometimes, it writes data about vehicle operation into memory or it reads data about how the vehicle should operate.

Multiple Sensor Inputs

The computer uses multiple inputs (inputs from more than one sensor) to determine the needed output. As shown in **Figure 17-32,** the computer uses signals from the engine speed sensor to determine when to fire the fuel injectors. However, if a temperature sensor signals a cold engine, the computer would know to increase injector pulse width to enrich the fuel mixture for good cold engine operation.

Multiplexing

A ***computer network*** is a series of electronic control units (small computers) that control different systems but work together to improve overall vehicle efficiency. Also called an *integrated computer system*, the network allows all the on-board computers to use feedback data from several systems (engine transmission, braking, suspension, traction control for example) to better control all vehicle systems. The term used to describe this computer interaction in vehicles is **multiplexing**.

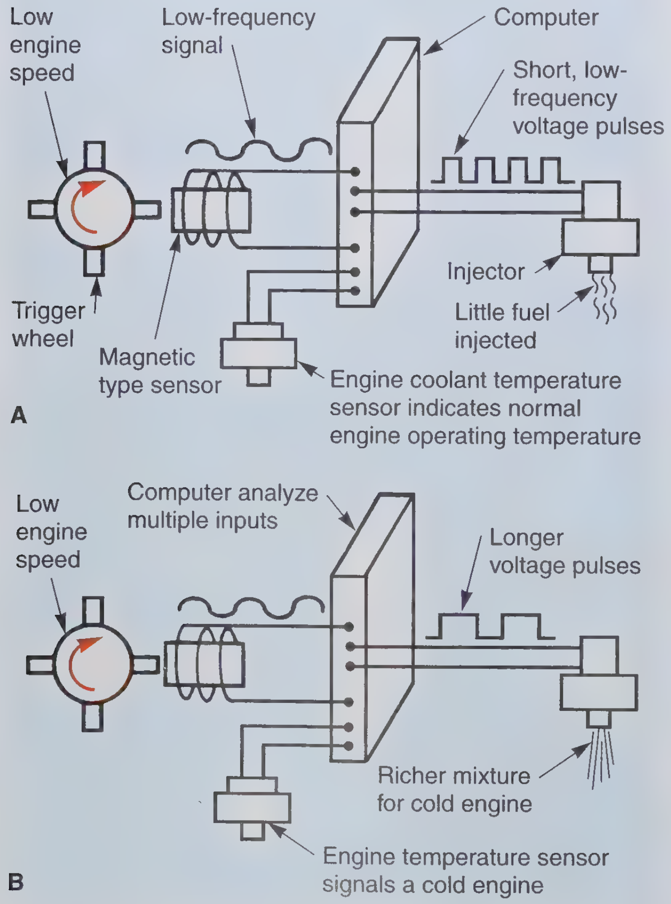
The computers in the network share common parts, such as wires, input signals, and output signals. They exchange data from sensors to prevent duplication of parts and to reduce wiring.

The wiring used for the network is often referred to as a ***data bus***. The signals traveling through the data bus are coded to indicate which computers the signals are being sent to, and in what order the signals should be processed. This prevents the signals from being processed by the wrong computer or in the wrong order.

Each computer and system needed for vehicle operation has its own default operating or limp-in mode, so the vehicle can be driven home or to a shop for service.

Some systems are controlled from a central computer instead of individual ones. This allows a single computer to monitor all functions to better decide how to control braking, throttle action, ride stiffness, engine management, and differential action for optimum efficiency.

In the near future, fiber optics, which use light to transmit data, may form the network connections. This will allow faster and simultaneous transmission of data from each computer.



Low engine speed
Low-frequency signal
Computer
Short, low-frequency voltage pulses
Injector
Little fuel injected
Trigger wheel
Magnetic type sensor
Engine coolant temperature sensor indicates normal engine operating temperature
A

Computer analyze multiple inputs
Longer voltage pulses
Richer mixture for cold engine
Engine temperature sensor signals a cold engine
B

Figure 17-32. A computer system uses more than one sensor input to make most control decisions. A—Low engine speed along with normal engine operating temperature causes the computer to produce a short pulse width to inject a small amount of fuel into the engine. B—If the engine coolant temperature sensor signals a cold engine, the computer would use both speed and temperature signals to increase injector pulse width to enrich the mixture for cold engine operation.

Actuators

Mentioned earlier, ***actuators*** are the "hands and arms" of a computer system. They allow computers to do work and alter the operation of other components.

Actuator Locations

Actuators can be found almost anywhere on a vehicle. They can be located on the engine, in the doors, under the hood, and in the trunk. Check an appropriate service manual for exact locations.

Actuator Classifications

A computer system uses several types of output devices, or ***actuators,*** to control part operation. All actuators can be grouped into the following categories:

- ***Solenoid***—current through the solenoid winding forms a magnetic field that moves a metal core. The core acts upon other components.
- ***Relay***—current from the computer energizes a relay to control high current to another electrical component.

- ***Servo motor***—current is sent to a small dc motor that can produce an output by moving parts.
- ***Display devices***—current is sent to a vacuum-fluorescent or liquid-crystal display to provide output data to the instrument cluster.
- ***Control module***—the computer sends an electrical signal to a control module. The module then amplifies and/or modifies the signal to operate a device.

Look at **Figure 17-33.** Imagine how these devices could be used to control engine, transmission, and other vehicle functions.

Actuator Operation

When the computer turns on an actuator, it normally provides the device with a ground circuit. Then, current can operate the actuator, **Figure 17-34.** The following sections detail the operation of the three most common actuator types: solenoids, relays, and servo motors.

Solenoid Operation

Figure 17-35 shows how the computer can use a solenoid to lock the vehicle's doors once a certain road speed is achieved. Input from the vehicle speed sensor enters the computer. When the computer detects vehicle travel or forward motion, it can use the solenoids to lock all the vehicle's doors.

The computer grounds the solenoid circuits and current flows through the solenoid windings. This produces a magnetic field in the windings. The magnetic field moves the plunger mounted in the solenoid windings. This plunger movement locks the doors.

Figure 17-35. Simplified illustration of how sensor inputs can be used by the computer to operate solenoids. When the vehicle speed sensor produces a signal, the computer grounds the door lock solenoid. The solenoid movement is used to lock the car doors automatically.

Relay Operation

A relay is often used as an actuator when a high-current load must be controlled by the computer. The computer will simply ground the relay coil windings. Then, the relay coil field will pull the mechanical contacts closed, allowing a large current to flow to the load, **Figure 17-36.**

Servo Motor Operation

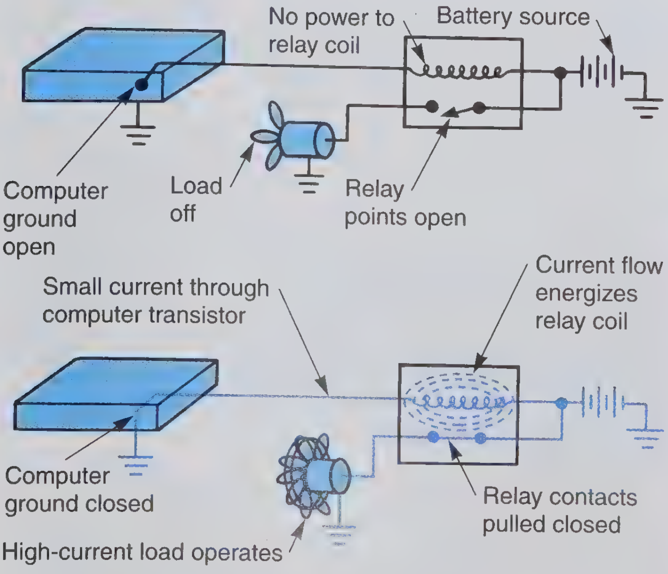
A servo motor provides another way for the computer to produce an output. The computer can ground the motor circuit, turning the motor on or off or reversing motor rotation as needed.

Sometimes, the servo motor is simply a reversible dc motor. The motor will turn a threaded mechanism to produce a controlled movement of a part. A good example would be an idle speed motor. Look at **Figure 17-37.** Note that some motors also serve as sensors for the computer. They can inform the computer as to their positions.

Specific Actuators

Some common actuators used on late-model vehicles include the following:

- ***Fuel injector***—solenoid valve that controls fuel flow.
- ***Fuel pump***—electric motor that drives a pumping mechanism to force fuel out of the tank and to the engine.
- ***Idle air solenoid***—controls airflow into the engine to help control idle speed.



No power to relay coil
Battery source

Coils energized
Rotor stops at energized coils
Coil off

Figure 17-37. A servo, or stepper, motor can be stopped in an exact position. The computer can energize specific coils to attract and stop the armature next to the energized coils.

- ***Idle speed motor***—small reversible dc motor that opens and closes the engine throttle valve to control idle speed.
- ***EGR solenoids***—solenoids that open and close small ports to control exhaust gas flow back into the engine to control emissions.
- ***Canister purge solenoids***—solenoids that control vacuum flow to draw fuel vapors into the engine for burning to reduce emissions.
- ***Door lock motors***—Solenoids that move latch mechanisms to lock or unlock the doors.
- ***Electric seat motors***—reversible dc motors that move the seat into the desired position.
- ***Ignition coil***—uses high current flow to change low voltage into the high voltage that operates the spark plugs.
- ***Ignition module***—electronic circuit that uses computer signals to control the operation of the ignition coils.

Highway History

In response to the Clean Air Act of 1977, manufacturers began producing "self-adjusting" engines. These engines, which were introduced in 1981, were equipped with feedback fuel-control systems. Early feedback systems consisted of an oxygen sensor to measure the oxygen content in the exhaust gases (an indication of air-fuel ratio), a small computer to analyze the oxygen sensor signal, and a mixture control device to make air-fuel ratio adjustments based on the computer's output signals. These simple systems were the predecessors to the powerful, complex computer systems found on today's vehicles.

Summary

- A computer is a complex electronic circuit that will produce programmed electrical outputs after receiving specific electrical input signals.
- The term cybernetics refers to the study of how electrical-mechanical devices can duplicate the action of the human body.
- The binary numbering system uses only two numbers, zero and one, and is the key to how computers operate.
- A gate is an electronic circuit that produces a specific output voltage for given input voltages.
- Digital signals are on-off signals, like those produced by a rapidly flipping switch.
- An analog signal changes in strength or has a variable voltage.
- A computer signal, waveform, or wave is a voltage variation over short periods of time.
- An integrated circuit is an electronic circuit that has been reduced in size and placed on the surface of a tiny semiconductor chip.
- A vehicle sensor is a transducer that changes a condition into an electrical signal.
- Circuit sensing involves using the computer itself instead of dedicated sensors to monitor computer and circuit operation.
- The computer sends a reference voltage to passive sensors so that a signal can be fed back for processing.
- A microprocessor in a small integrated circuit capable of analyzing data and calculating appropriate outputs.
- Computer memory uses gates that are capable of storing data as voltage charges.
- The three basic types of computer memory are RAM, ROM, and PROM.
- Output drivers control current flow through the actuators.
- A computer network is a series of computers that control different systems but work together to improve overall vehicle efficiency.
- Actuators allow the computer to alter the operation of other components.

Review Questions—Chapter 17

Please do not write in this text. Place your answers on a separate sheet of paper.

1. Define the term "cybernetics."
2. The binary numbering system uses only _____ and _____ and is the key to _____ _____.
3. Describe the five basic types of computer gates.
4. Name and describe the two general sensor classifications.
5. An active sensor requires a reference voltage. True or False?
6. Typically, a reference voltage is about _____.
7. Explain seven types of computers used on a car.
8. What is an EPROM?
9. What is meant by the term "adaptive strategy"?
10. _____ are the "hand and arms" of a computer network.

ASE-Type Questions

1. Technician A says the term "cybernetics" refers to the study of how chemical-mechanical devices can duplicate the action of the human body. Technician B says the term "cybernetics" refers to the study of how electrical-mechanical devices can duplicate the action of the human body. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
2. Which of the following are known as the "linking cells" of the human brain?
   (A) Neutrons.
   (B) Neurons.
   (C) Protons.
   (D) None of the above.
3. Technician A says digital electronics deals with the way an alternator charges a battery. Technician B says digital electronics deals with the way a computer system uses discrete on and off signals to produce artificial intelligence. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Which of the following uses only two numbers, zero and one, and is the key to computer operation?
   (A) Electronic system.
   (B) Base 10 system.
   (C) Decimal system.
   (D) Binary System.
5. Technician A says the numbers 1 and 2 are used in the binary numbering system. Technician B says the numbers 0 and 1 are used in the binary numbering system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
6. Technician A says in computer language a 0 or 1 is called a byte. Technician B says in computer language a 0 or 1 is called a bit. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Technician A says the term "gate" refers to an electronic circuit that stops current from flowing in a particular direction. Technician B says the term "gate" refers to an electronic circuit that produces a specific output voltage for given input voltages. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
8. Technician A says an AND gate requires voltage at both inputs to produce a voltage at the output. Technician B says an AND gate requires voltage at only one input to produce a voltage at the output. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. Technician A says both inputs of a NAND gate must be *on* to produce an output. Technician B says both inputs of a NAND gate must be *off* to produce an output. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

10. Technician A says an IC is an electronic circuit that has been reduced in size and etched on the surface of a semiconductor chip. Technician B says an IC is a small amplifier circuit for increasing output strength. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
11. Technician A says a variable resistor sensor opens or closes the sensor circuit to provide an electrical signal for the computer. Technician B says a variable resistor sensor changes its internal resistance with a change in a condition. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
12. Which of the following is another name for an automotive computer?
    (A) Electronic Control Unit.
    (B) Electronic Control Module.
    (C) Electronic Control Assembly.
    (D) All of the above.
13. Technician A says an automotive computer can be located under the dash. Technician B says an automotive computer can be located in the automobile's engine compartment. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
14. Which of the following memories can be altered in the field to adjust for operating parameters?
    (A) EEPROM.
    (B) XPROM.
    (C) KAM.
    (D) RAM.
15. Technician A says a servo motor is one type of output device used in an automotive computer system. Technician B says a solenoid is one type of output device used in an automotive computer system. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Activities—Chapter 17

1. Convert your ZIP Code or your telephone number into binary number form. Make a chart that shows how the decimal numbers were converted to binary.
2. Visit several automobile dealerships and gather literature on the anti-lock brake systems offered on their cars. If possible, compare the number of models that offer ABS as standard equipment. Also compare the cost of ABS systems as an option from different manufacturers.

18

On-Board Diagnostics and Scan Tools

After studying this chapter, you will be able to:

- Discuss the purpose and operation of on-board diagnostic systems.
- Explain the use of scan tools to simplify reading of trouble codes.
- Compare OBD I and OBD II system capabilities and procedures.
- Locate the data link connector on most makes and models of cars.
- Activate on-board diagnostics and read trouble codes with and without a scan tool.
- Use a trouble code chart in a service manual or code conversion by a scan tool.
- Erase diagnostic trouble codes.
- Correctly answer ASE certification test questions concerning late-model on-board diagnostics and scan tool use.

On-board diagnostics refers to a vehicle computer's ability to analyze the operation of its circuits and to output data showing any problems. All late-model cars and light trucks have this self-test feature. It is critical that you know how to use this vital troubleshooting aid.

Today, the first thing a technician often does when diagnosing a problem in a computerized system is check for diagnostic trouble codes with a scan tool.

Introduced in Chapter 4, a ***scan tool*** is used to communicate with the vehicle's computers to retrieve trouble codes, display circuit and sensor electrical values, run tests, and give helpful hints for finding problems. This can all be done quickly and easily, without disconnecting wires or removing parts.

This chapter will summarize recent changes in on-board diagnostic capabilities and explain the fundamental use of scan tools. It will prepare you for other text chapters on troubleshooting and servicing vehicle systems.

Note!
This chapter provides the basics of using scan tools and reading trouble codes. More advanced scan tool functions are explained at the beginning of most service chapters and are covered in detail in Chapter 46, *Advanced Diagnostics.*

On-Board Diagnostic Systems

Modern automotive computer systems are designed to detect problems and indicate where they might be located. The computer is programmed to detect abnormal operating conditions. It actually scans its input and output circuits to detect an incorrect voltage, resistance, or current.

Today's on-board diagnostics will check the operation of almost every electrical–electronic part in every major vehicle system. A vehicle's engine control module can detect engine misfiring and air-fuel mixture problems. It monitors the operation of the fuel injectors, ignition coils, fuel pump, emissions system parts, and other major components that affect vehicle performance and emissions control.

You can scan for problems in the engine and its support systems, the transmission, the suspension system, the anti-lock brake system, and other vehicle systems. This has greatly simplified the troubleshooting of complex automotive systems.

If the on-board computer finds any abnormal values, it will store a trouble code and light a malfunction indicator light on the instrument panel. This will inform the driver and the technician that something is wrong and must be fixed.

Since some vehicles have six or more computers, on-board diagnostics can be a time-saver when trying to narrow down possible problems. The computers can interact with dozens of sensors and actuators and, in some cases, with each other.

No longer can the untrained "shade tree mechanic" hope to repair modern vehicles. It takes the skill of a well-trained technician versed in on-board diagnostics to troubleshoot and repair today's vehicles.

Early On-Board Diagnostic Systems

Most early on-board diagnostic systems can check only a limited number of items. Although these older systems are able to detect a problem in the circuit, they were unable to determine what type of problem the circuit has (faulty wiring, defective component, etc.). Technicians who are unfamiliar with a particular manufacturer's line of vehicles may find it difficult to accurately diagnose problems caused by a computer system fault.

Also, there is little or no standardization among these early systems. A wide range of connectors and methods are used to retrieve stored trouble codes. This makes it confusing for tool manufacturers and technicians. It also makes it necessary for the shop or technician to purchase a variety of harness adapters, program cartridges, and service literature. Even the names of the systems and their components differ from manufacturer to manufacturer, making part identification difficult.

Early diagnostic systems are often referred to as ***OBD I (on-board diagnostics generation one) systems***. See **Figure 18-1**. There are still millions of vehicles on the road that use OBD I systems.

OBD II Systems

A malfunctioning automobile engine can be a significant source of air pollution. It can produce several times the normal amount of harmful exhaust emissions. For this reason, the Environmental Protection Agency (EPA) recommended and passed regulations that require on-board diagnostic systems to detect potential problems *before* they result in the production of harmful exhaust emissions. These regulations also require auto manufacturers to standardize the performance monitoring systems on their cars and light trucks.

As mentioned, OBD I systems simply store a code and illuminate a dash light once a sensor or circuit stops working completely. The new standard requires on-board diagnostic systems to go a step further by monitoring how efficiently each part of the system is operating.

OBD II (on-board diagnostics generation two) systems are designed to more efficiently monitor the condition of hardware and software that affect emissions. OBD II systems detect part deterioration (changes in performance), not just complete part failure. For example, if a sensor becomes lazy or remains in the low end of its normal operating range, this problem is stored as a trouble code in the computer memory for retrieval at a later date. Refer to **Figure 18-1**.

OBD II systems are designed to keep the vehicle running efficiently for at least 100,000 miles (160 000 km). The on-board computers used in OBD II systems have greater processing speed, more memory, and more complex programming than computers used in OBD I systems.

New vehicles now monitor more functions and can warn of more problems that affect driveability and emissions. OBD II systems can produce *over 500* engine-performance-related trouble codes. They check the operation of switches, sensors, actuators, in-system components, wiring, and the computer itself.

OBD II systems also have standardized data link connections, trouble codes, sensor and output device terminology, and scan tool capabilities. In the past, one manufacturer required over a dozen different connectors for the ECMs used in their vehicles. This made it very difficult for the small repair shop to purchase all the necessary adapters. To solve this problem, the federal government and the Society of Automotive Engineers (SAE) have set standards for all auto makers to use.

Malfunction Indicator Light (MIL)

If an unusual condition or electrical value is detected, the computer will turn on a warning light in the instrument panel or the driver information center. The warning light will notify the driver that the vehicle needs service. OBD I systems use a red- or amber-colored ***check engine light***, service engine soon light, or other indicator light with a similar name. Some vehicles have a silhouette of an engine on their warning lights.

In OBD II systems, the engine warning light is referred to as a ***malfunction indicator light (MIL)***. If the MIL *glows continuously*, the trouble is not critical but should be repaired at the vehicle owner's convenience. If the MIL light comes on and then goes out, the problem may be intermittent.

A *flashing* MIL in an OBD II equipped vehicle means that the trouble could damage the catalytic converter and is, therefore, considered critical. For example, an engine misfire (engine not completely burning fuel mixture) or a fuel system malfunction will generally cause the malfunction indicator light to flash on and off. This warns the driver that the catalytic converter may be overheated and burned if the vehicle is not serviced immediately. The MIL will flash on and off every second when conditions that could damage the converter exist.

Whenever the MIL is illuminated, drivers should be advised to bring the vehicle in for service as soon as possible. The technician can then use a scan tool to retrieve information about the problem.

A ***trouble code chart*** in the service manual will state what each number code represents. Most scan tools can

perform trouble code conversion. ***Trouble code conversion*** means the scan tool is programmed to automatically convert the number code into abbreviated words that explain the potential problem. The technician can then use service information to further isolate the problem.

Diagnostic Trouble Codes

Diagnostic trouble codes (DTC) are digital signals produced and stored by the computer when an operating parameter is exceeded. An ***operating parameter*** is an acceptable minimum and maximum value. The parameter might be an acceptable voltage range from the oxygen sensor, a resistance range for a temperature sensor, current draw from a fuel injector coil winding, or an operational state from a monitored device. In any case, the computer "knows" the operating parameters for most inputs and outputs. This information is stored in its permanent memory chips.

Computer System Problems

Common problems that can affect vehicle performance and cause the computer system to set a code and light the MIL in the dash are shown in **Figure 18-2.** These problems include:

- *Loose electrical connection*—input signal from a sensor not reaching the computer properly or an actuator not responding to the computer's output.

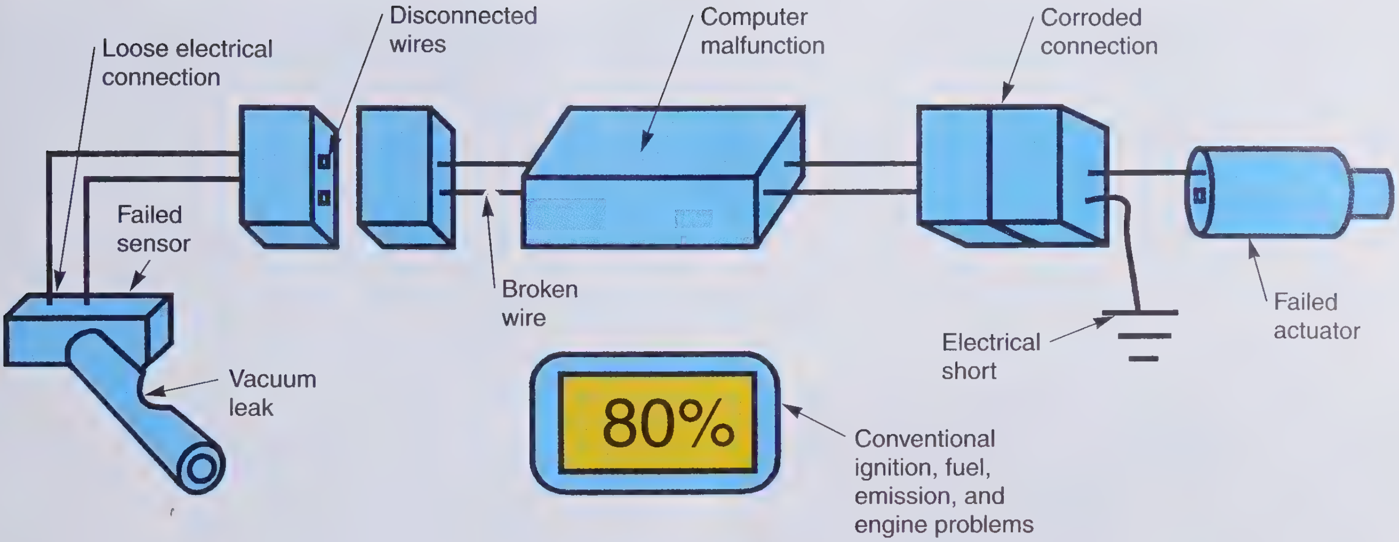

Figure 18-2. Always remember that about 80% of all performance problems are *not* caused by the computer, its sensor, or its actuators. Most problems are the result of conventional problems, such as loose connections, broken wires, vacuum leaks, mechanical problems, etc.

- *Corroded electrical connection*—high resistance in a wiring connector, upsetting sensor input or actuator output.
- *Failed sensor*—opened or shorted sensor or other sensor malfunction preventing normal computer system operation.
- *Failed actuator*—solenoid, servo motor, relay, or display shorted, open, or does not react to computer signals.
- *Leaking vacuum hose*—vacuum leak or poor operation of engine or vacuum-operated actuator that reduces engine or system performance.
- *Electrical short*—wires touching ground or each other to cause a current increase or incorrect current path.
- *Ignition system problems*—open spark plug wires, fouled spark plugs, weak ignition coil voltage, bad crankshaft sensor, etc. For example, a spark plug misfire causing unburned fuel to enter the exhaust can trick the oxygen sensor into trying to create a leaner mixture. The misfire upsets computer system operation and can be detected in OBD II systems by variations in the crankshaft sensor signal.
- *Fuel system problems*—leaking or clogged injectors, bad pressure regulator, faulty electric fuel pump, or other problems.
- *Emission system problems*—problems with the catalytic converter, EGR valve, vapor storage system, etc. Many emission components are monitored electronically and will set a trouble code if a malfunction occurs.
- *Engine problems*—mechanical problem that cannot be compensated for by the computer modifying system operation. Engine misfire due to mechanical wear will also trip a trouble code on OBD II systems.
- *Computer malfunction*—an incorrect PROM, wrong internal programming, internal failure of an integrated circuit, or failure of other components can disable the computer and alter the operation of related systems.
- *Weak or lazy component*—sensor, actuator, or computer is not outputting normal operating values. In some cases, a sensor's current, voltage, or resistance values are within specs, but the component is sending signals to the ECM at a reduced rate of speed. A lazy sensor can trick the computer system into compensating for an artificial lean or rich condition; it may trip codes on OBD II-equipped vehicles.
- *Transmission problems*—electronically controlled transmissions are monitored and will trip trouble codes if there is a mechanical problem. Transmission problems include a bad vehicle speed sensor, a faulty shift sensor or solenoid, or faulty wiring.
- *Anti-lock brake system problems*—modern anti-lock brakes are monitored by an on-board computer. Anti-lock brake system problems include

bad wheel speed sensors, faulty wiring, or a malfunctioning hydraulic unit.

- *Air conditioning*—today's air conditioning systems are also monitored electronically for operational state, leaks, and high pressure. Typical problems include faulty pressure and temperature sensors.
- *Air bag problems*—problems with the air bag system, such as faulty impact sensors, a malfunctioning arming sensor, or a damaged air bag module, will trip trouble codes.
- *Other system faults*—most other vehicle systems have some monitored functions that will trip a trouble code.

Tech Tip!
Most computer system problems are conventional (loose electrical connection, mechanical problem, etc.). Only about 20% of all performance problems are caused by an actual fault in the computer or one of its sensors. For this reason, always check for the most common problems before testing more complex computer-controlled components.

Scanning Computer Problems

A scan tool is an electronic test instrument designed to retrieve trouble codes from the computer's memory and to display the codes as a number and words identifying the problem. Also called a *diagnostic readout tool*, the scan tool makes it easier to read diagnostic trouble codes. In some cases, it is the only way to access the computer's diagnostic system. Refer to **Figure 18-3.**

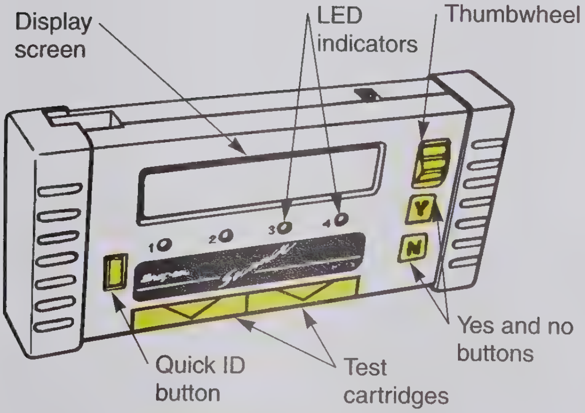

Figure 18-3. A scan tool is now the most important tool of the automotive technician. It will tell you where problems are located. (Snap-on Tools)

A scan tool is by far the most common way to use on-board diagnostics. It will save time and effort. A scan tool is now the most important tool of the automobile technician, **Figure 18-4.**

To use the scan tool, read the operating instructions for the specific tool at hand. Operating procedures vary. Some scan tools have buttons to control functions. Others have a rotary knob that lets you scroll down through scan tool functions.

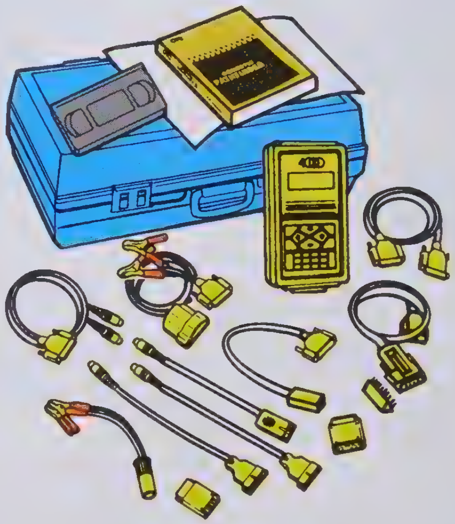

Figure 18-4. Scan tool designs vary. Always read the owner's manual that comes with the tool before use. (OTC)

Scan Tool Program Cartridges

Most scan tools come equipped with several ***program cartridges.*** These removable cartridges house one or more computer chips that contain specific information about the vehicle to be scanned, **Figure 18-5.**

One type of scan tool cartridge is a *vehicle program cartridge*. This type of program cartridge provides data for one or more vehicle manufacturers (GM, Ford, Chrysler, Asian, European, etc.). Scan tool cartridges must match the model year (vehicle manufacturing date). Program cartridges are also available for certain systems, such as anti-lock brakes, automatic transmissions, etc.

New cartridges must be purchased as the on-board diagnostic systems are modified. Some scan tool manufacturers now offer generic storage cartridges that can be updated by downloading the up-to-date specifications to the scan tool from a computer.

Caution!
Avoid touching the cartridge or scan tool terminals. Static electricity can destroy the delicate electronics in these units. See **Figure 18-6.**

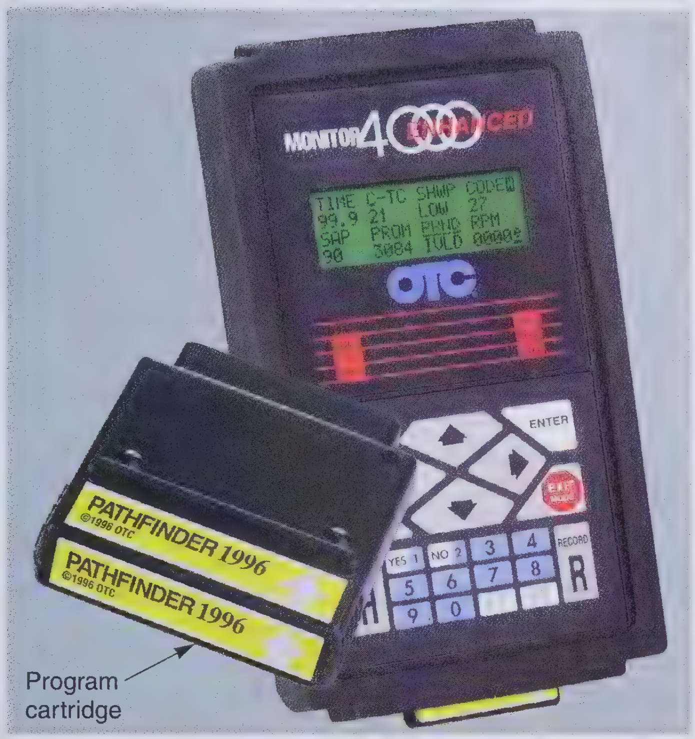

Figure 18-5. Scan tool cartridges contain stored information for troubleshooting a specific make, model, and year of vehicle. Troubleshooting cartridges sometimes give added instructions to help solve a problem. (OTC)

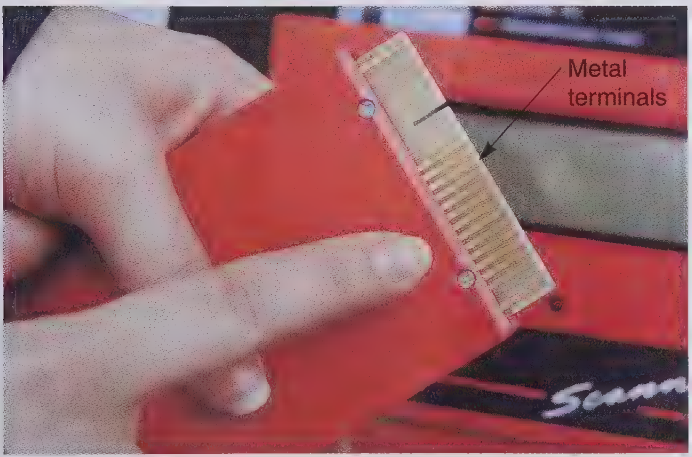

Figure 18-6. When installing a cartridge into a scan tool, do not touch the metal terminals. Static electricity could damage the cartridge's internal chips or electronics. (Snap-on Tools)

A few scan tools also come with a ***troubleshooting cartridge,*** which gives additional information on how to verify the source of various trouble codes. This is a handy device that can help guide you to the most common sources of trouble. However, the troubleshooting cartridge must be used in conjunction with the vehicle cartridge. This makes it necessary to have a scan tool that can access two cartridges at the same time.

Many scan tools will hold two cartridges, one for the vehicle being tested and another for added convenience. However, most scan tools can access the information from one cartridge at a time. A few scan tools can access both cartridges at the same time. This capability allows for the use of the troubleshooting cartridge discussed earlier. Install the right cartridge(s) into the scan tool. Slide the cartridge straight into the tool to prevent damage. Look at **Figure 18-7.**

Data Link Connector (Diagnostic Connector)

The ***data link connector (DLC)*** is a multipin terminal used to link the scan tool to the computer. In the past, this connector was identified by a variety of names, including ***diagnostic connector*** and ***assembly line diagnostic link (ALDL).***

OBD I data link connectors came in various shapes and sizes, and were equipped with a varying number of pins or terminals. With OBD II, the DLC is a *standardized* 16-pin connector. The female half of the connector is on the vehicle, and the male half is on the scan tool cable.

Some of the most common locations for the diagnostic connector include:

- Under the dash or the center console, within arm's reach when sitting in the driver's seat, **Figures 18-8A** and **18-8B.** These are the standard OBD II locations.
- Behind the dashboard, **Figure 18-8F.**
- Near the firewall in the engine compartment, **Figure 18-8C.**
- Near or on the side of the fuse box, **Figure 18-8D.**
- Near the inner fender panel in the engine compartment, **Figure 18-8E.**

Figure 18-8. Data link connector locations vary. A—OBD II vehicles have their data link connector below the dash, within easy reach of the driver's seat. B—The OBD II connector is sometimes located in the center console. C—Some Ford diagnostic connectors are on the firewall, near the back of the engine. D—Some early General Motors connectors are next to the fuse box. E—Early Chrysler diagnostic connectors are located in the engine compartment. F—Other data link connectors may be located behind the dash, in or behind the glove box, under the center console, etc. Refer to the service manual if needed.
(General Motors, Ford, and Snap-on Tools)

With OBD II diagnostic systems, you should be able to connect a scan tool to the vehicle's data link connector with one hand while sitting in the driver's seat or kneeling outside the vehicle.

Tech Tip!
Some OBD I vehicles are equipped with a 16-pin, OBD II–style data link connector. Do not assume that a vehicle equipped with a 16-pin connector is OBD II compliant.

Connecting the Scan Tool

The scan tool cable should slide easily into the vehicle's data link connector. If not, something is wrong. Never force the two together or you could damage the pins on the tool cable or the data link connector. You may have to use an ***adapter*** so the scan tool connector will fit the vehicle's DLC or communicate with different pin configurations, **Figure 18-9.**

If the scan tool is not powered through the DLC, connect the tool to battery power. In most cases, you can use a cigarette lighter adapter to connect power to the scan tool. See **Figure 18-10.** You can also use alligator clips to connect the tool to the battery.

Caution!
Make sure you are connecting the scan tool to the vehicle properly. Some technicians have mistakenly connected scan tools to the wrong connector (tach connector, for example), which can damage the scan tool.

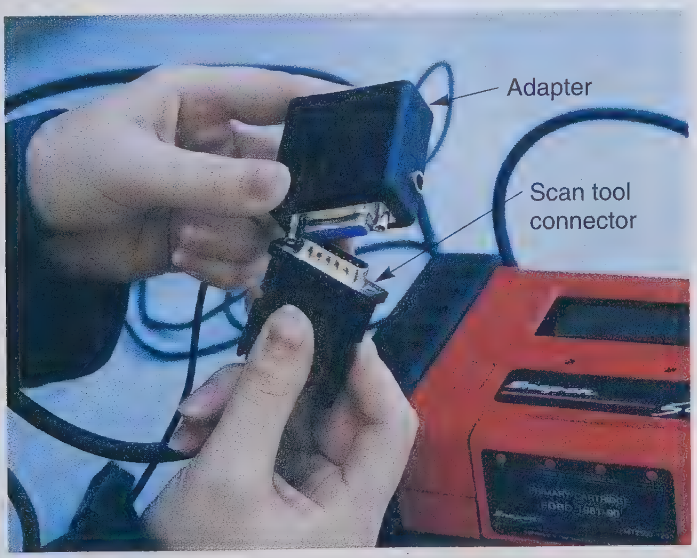

Figure 18-9. An adapter is sometimes needed between the scan tool cable and the vehicle's data link connector. As OBD II–equipped vehicles become more commonplace, these adapters will be needed less. (Snap-On Tools)

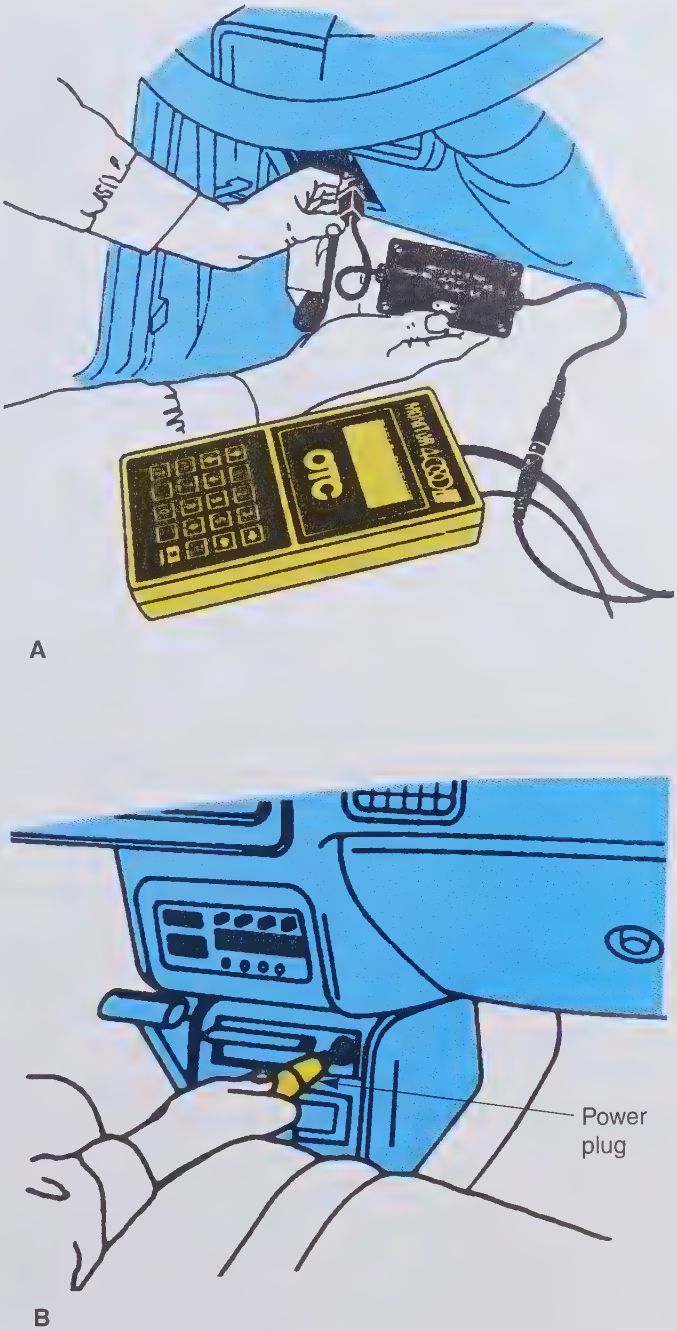

Figure 18-10. A—Connect the scan tool cable to the vehicle's data link connector. Make sure the pins match up. Do not force them together. B—If necessary, scan tools can be powered by a cigarette lighter plug or connected directly to the battery. (OTC)

Using Scan Tools

Modern scan tools will give ***prompts,*** or step-by-step instructions, in their display windows. The prompts tell you how to input specific vehicle information and run diagnostic tests. See **Figure 18-11.** Scan tool instructions are procedures and specifications programmed into the cartridge.

Figure 18-11. Controls on a scan tool will vary by manufacturer. A—This scan tool uses a keypad and arrow keys for inputting requested information about the vehicle and desired tests. B—This scan tool has an easy-to-use rotary knob and yes–no buttons for inputting requested data. (OTC and Snap-on Tools)

First, the scan tool may ask you to input VIN information from the plate on the top of the dash. You may be asked to input specific numbers and letters from the VIN. Refer to **Figure 18-12.**

The VIN data lets the scan tool know which engine, transmission, and options are installed on the vehicle. With some makes, however, the on-board computer will contain this data and will automatically download it into the scan tool. Then, you will be able to select the information that you would like the scan tool to give you. Some of the information you can request includes:

- *Stored diagnostic trouble codes*—gives trouble codes.
- *Fault description*—explains what each stored diagnostic code means. This information is given with the trouble codes on most scan tools.
- *Datastream information*—displays the operating values of all monitored circuits and sensors.
- *Run tests*—performs sensor and actuator tests.
- *Oxygen sensor monitoring*—performs detailed tests of the O_2 sensor signal.
- *Failure record*—lists the number of times a particular trouble code has occurred by keystarts or warm-ups.
- *Freeze frame*—takes a snapshot of sensor and actuator values when a problem occurs.

SELECT 10th VIN CHARACTER
VIN:
VEHICLE:
ENGINE:

Figure 18-12. The scan tool may ask you to input VIN information. This lets the tool know how the vehicle is equipped—engine type, fuel system type, computer configuration, etc. (Snap-on Tools)

- *Troubleshooting*—Provides help and instructions for diagnosing faults.

Figure 18-13 gives the general sequence for using a scan tool. You can ask the scan tool to give more information on a trouble code, and the tool will display words that give sensor resistance values, identify common problems, and provide other useful information. **Figures 18-14** and **18-15** show some examples of scan tool troubleshooting tips.

As stated earlier, some scan tools are able to take a snapshot, or ***freeze frame,*** of sensor and actuator values when a problem occurs. The tool records the values from all monitored components so they can be further evaluated. This helps you locate and correct intermittent problems more easily.

Figure 18-15. A key-on/engine-on test is sometimes needed to further diagnose problems. You must allow the engine to reach operating temperature first so all sensors are operating normally.

Tech Tip!

Most technicians check the ECM for stored diagnostic trouble codes before performing tests on specific components. This is a quick way to pinpoint any hard failures, so they can be repaired first.

Always correct the cause of the *lowest number* diagnostic trouble code first. Sometimes, fixing the cause of the lowest code will clear other codes because of component interaction. If not, you can use other scan tool features to find and solve more complex problems. A trouble code does *not* mean that a certain component is bad. It simply indicates that a possible problem has been detected in that particular device or circuit.

Most ECMs count the number of times a trouble code has occurred. This information is stored in a ***failure record,*** or *failure recorder,* that also indicates the number of keystarts since the last time the trouble code occurred. The failure recorder in OBD II systems counts the number of times the engine reached operating temperature, rather than keystarts, since the last time the code was set. If one code has occurred more frequently than the others, investigate this code first. In many cases, the lowest number code and the most frequently stored code are the same.

Diagnostic Trouble Code Identification

As mentioned, early on-board diagnostic systems were not standardized. Often, technicians would have to refer to the service manual to find out what a particular code number meant. OBD I and earlier codes were different for each manufacturer.

To simplify troubleshooting, OBD II requires all auto manufacturers to use a set of ***standardized alpha-numeric trouble codes.*** Each trouble code identifies the same problem in all vehicles, regardless of the manufacturer.

OBD II codes contain a letter and a four-digit number. The letter in all OBD II codes indicates the *general function* of the affected system (power train, chassis, etc.).

The first digit of the number indicates whether the code is a standard trouble code or a nonuniform code. ***Standard trouble codes,*** or SAE codes, are indicated by the number *0*. ***Nonuniform codes*** (nonstandard OBD II codes that are assigned by the auto manufacturers) have the number *1* after the system letter. The second digit of the OBD II code number indicates the *specific function* of the system where the fault is located, such as fuel, computer, etc.

The code's last two digits refer to the specific fault designation. The ***fault designation*** pinpoints exactly which component or circuit of the system might be at fault, as well as the type of problem. Regardless of the type of vehicle being serviced, the core trouble code numbers will be the same. The scan tool must explain the code and, in some cases, may describe how to fix the problem.

Figure 18-16 gives a breakdown of the OBD II diagnostic code. Study it carefully. **Figure 18-17** shows the display of a scan tool that has found a stored trouble code.

C—Options will allow you to use the scan tool to get detailed descriptions of each code, list possible causes, or perform diagnostic tests. (OTC)

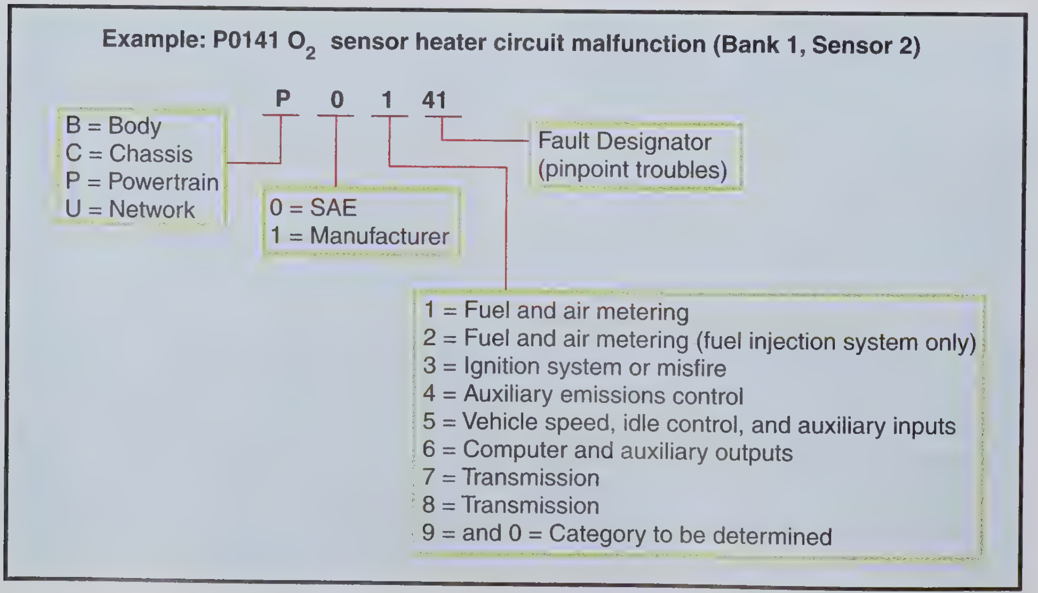
Failure Types

There are two general types of computer system failures: hard failures and soft failures. A ***hard failure*** is a problem that is always present in a computer system. An example of a hard failure is a disconnected wire or another problem that would cause a general circuit failure. A hard failure does not come and go with varying conditions. After the computer memory is cleared, any hard failures will usually reset as soon as the engine is started or the affected system is energized.

A ***soft failure,*** or *intermittent failure,* is a problem that only occurs when certain conditions are present. It might be present one minute and gone the next. Soft failures will usually be stored in memory for 30-50 key starts or engine warm-ups. An example of a soft failure is a loose terminal that connects and disconnects as the vehicle travels over bumps in the road. Low-input, high-input, and improper range failures are usually classified as soft failures.

Computer system failure types can be further broken down into four general categories:

- A ***general circuit failure*** means the circuit or component has a fixed value, no output, or an output that is out of specifications. This is the most severe fault, but it is the easiest to locate. It is caused by disconnected wires, high-resistance connections, shorts, or a component constantly operating out of parameter.



Example: P0141 O2 sensor heater circuit malfunction (Bank 1, Sensor 2)
P 0 1 41

(pinpoint troubles)
1 = Fuel and air metering
2 = Fuel and air metering (fuel injection system only)
3 = Ignition system or misfire
4 = Auxiliary emissions control
5 = Vehicle speed, idle control, and auxiliary inputs
6 = Computer and auxiliary outputs
7 = Transmission
8 = Transmission
9 = and 0 = Category to be determined

Figure 18-16. OBD II trouble codes are alpha-numeric. Note what each part of the trouble code means. The first part of the code tells you which system is having problems. The last part of the code identifies the specific problem circuit or component.

- A ***low-input failure*** is one that produces a voltage, current, or signal frequency below normal operating parameters. A weak or abnormally low signal is being sent to the on-board computer. This type of failure is often caused by high circuit resistance, a poor electrical connection, a contaminated or failed sensor, or a similar problem.
- A ***high-input failure*** results when the signal reaching the on-board computer has a much higher voltage, current, or frequency than normal. This type of failure is often caused by a faulty sensor, a high charging voltage, or a mechanical fault that is "fooling" the computer system.
- An ***improper range/performance failure*** occurs when a sensor or actuator is producing values slightly lower or higher than normal. The circuit is still functioning, but not as well as it should under normal conditions. This type of failure can be caused by a contaminated sensor, a partial sensor failure, a poor electrical connection, and similar problems. Improper range/performance failures were not detected in OBD I systems and were often difficult to find. OBD II systems can detect improper range/performance failures.

Figure 18-18. Most technicians check for stored trouble codes first. A—This scan tool readout shows a problem with the intake air (air charge) temperature sensor. B—You would then know to check that sensor and its wiring for problems.
(Snap-on Tools)

Datastream Values

Datastream values, or diagnostic scan values, produced by the vehicle's computer give electrical operating values of sensors, actuators, and circuits. These values can be read on a scan tool's digital display and compared to known normal values in the service manual. Datastream values give additional troubleshooting information when trying to locate a problem.

Note!
For more information on scan tools and datastream values, see Chapter 46, *Advanced Diagnostics.*

Key-On/Engine-Off Diagnostics

In order to access the ECM data on most vehicles, it is necessary to turn the ignition key on. ***Key-on/engine-off diagnostics*** are performed by triggering the ECM's on-board diagnostic system with the ignition key in the *on* position but *without* the engine running. This allows you to access any stored trouble codes in the computer's memory chips. Key-on/engine-off diagnostics are usually performed *before* key-on/engine-on diagnostics. Look at **Figure 18-18.**

If you anticipate working in the key-on/engine-off diagnostic mode for over 30 minutes, connect a battery charger to the vehicle. This will prevent the extended current draw from draining the battery and upsetting the operation of the computer while in the diagnostic mode. False trouble codes could result from a partially drained battery.

Wiggle Test

Many computer system failures, especially intermittent failures, are caused by loose, dirty, or corroded connections. These failures can be found by performing a ***wiggle test,*** or "flex" test.

To perform a wiggle test:

1. Connect a scan tool to the vehicle and choose the appropriate test options. Refer to the instructions provided with the scan tool.
2. Place the vehicle in the key-on/engine-off diagnostic mode.
3. Flex wires and wiggle harness connectors while scanning for problems.
4. If wiggling a wire or connector produces a new diagnostic trouble code, check the wire or electrical connection more closely. It may be loose, corroded, or damaged, **Figure 18-19.**

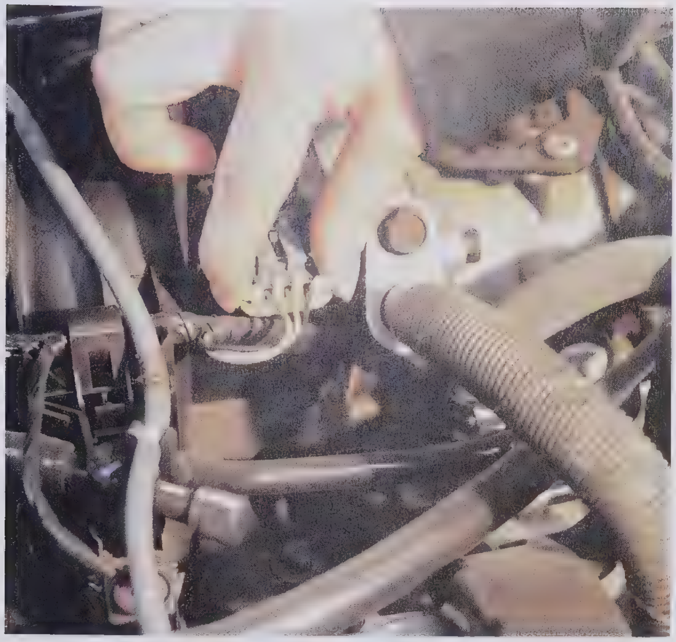

Figure 18-19. The wiggle test involves moving wires and connectors while scanning for trouble codes. If wiggling a wire trips a code, you found the location of the problem.

Some technicians perform a wiggle test while the engine is running. If engine operation changes suddenly (stalls or idles high, for example) when a connector or wire is flexed, the problem is located at or near that point. Be careful when performing a wiggle test on a running vehicle.

You might also want to use a heat gun to heat potentially faulty components during a wiggle test. For example, electronic amplifiers and modules tend to malfunction when hot. This could help find an intermittent problem.

Caution!
Exercise care when using a heat gun. The heat generated by the gun can easily melt most plastics and damage electronic components.

Key-On/Engine-On Diagnostics

Key-on/engine-on diagnostics are performed with the engine running at full operating temperature. These tests check the condition of the sensors, actuators, computer, and wiring while they are operating under normal conditions.

Switch Diagnostic Test

A ***switch diagnostic test*** involves activating various switches while using a scan tool. The scan tool will tell you which switch to move and will monitor its operation. The scan tool will quickly indicate if the switch is working normally, **Figure 18-20.**

For example, you might be told to shift the transmission shift lever through the gears, press on the brake pedal, and turn the air conditioning on and off. As each step is performed, the scan tool will indicate if the affected switch is *OK and* whether or not the ECM is reading the switch input. Refer to the service manual for details of the switch diagnostic test.

Actuator Diagnostic Tests

An ***actuator diagnostic test*** uses the scan tool to order the vehicle's computer to energize specific output devices with the engine on or off. This will let you find out if the actuators are working. Most actuator diagnostic tests are considered intrusive tests, since engine or vehicle operation will be drastically affected while the device is being tested. Actuator diagnostic tests might:

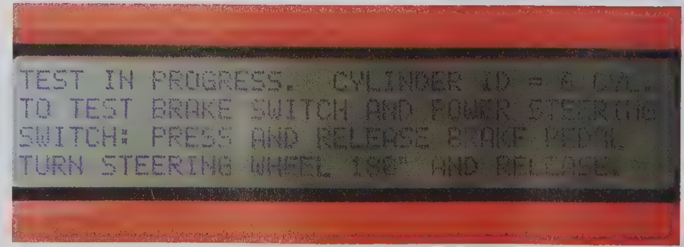
- Fire or prevent the firing of the ignition coil.
- Open and close the fuel injectors.
- Cycle the idle speed motor or solenoid.
- Energize the digital EGR valve solenoids.

You can then watch or listen to make sure these actuators are working. With OBD II, the scan tool will give readouts showing whether there is trouble with any actuators.

Switch and actuator diagnostic tests cannot be performed on all vehicles. Refer to the service manual or scan operating manual for details.

Scanning During a Test Drive

With a modern scan tool, you can also check for problems while driving the vehicle to simulate the conditions present when the trouble happens, **Figure 18-21.** For example, if the problem occurs only while driving



```
TEST IN PROGRESS.  CYLINDER ID = 6 CYL.
TO TEST BRAKE SWITCH AND POWER STEERING
SWITCH: PRESS AND RELEASE BRAKE PEDAL
TURN STEERING WHEEL 180° AND RELEASE.
```

Figure 18-20. Most scan tools will also perform switch and actuator tests. This is sometimes done automatically. You may be prompted to close different switches to make sure each one is working. The scan tool may also be able to perform additional actuator tests. (Snap-on Tools)

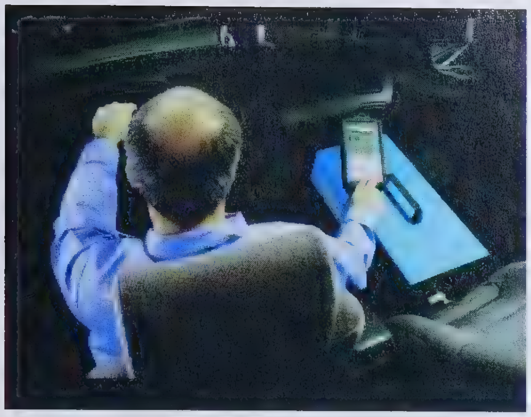


Figure 18-21. Scan tools are sometimes used while test driving vehicles. This will allow you to check engine and vehicle operating parameters while duplicating the conditions present when the problem occurred. (OTC)

at a specific speed when the engine is cold, you can scan under these conditions. Start the cold engine and drive at the specified speed while scanning for problems. You can then take a snapshot, or freeze-frame, (if the scan tool has this feature) when the problems occur. For more information on advanced diagnostics, refer to Chapter 46.

Energizing OBD I Systems Without a Scan Tool

If you do not have a scan tool and are working on an OBD I–equipped vehicle, there are several ways to activate the computer's on-board diagnostics and retrieve trouble codes, **Figure 18-22.** The most common methods include:

- Using a jumper wire to ground one of the data link connector terminals and then reading the flashing code on the dash-mounted check engine light, **Figure 18-23.**
- Connecting an analog voltmeter to vehicle ground and to one terminal on the data link connector while jumping from the pigtail (extra wire) to the data link connector. The code is produced by the meter's needle movement.
- Turning the ignition key on and off several times within a few seconds and reading the flashing code on the dash-mounted check engine light. See **Figure 18-23.**
- Pushing two dash-mounted climate control buttons at the same time and reading the dash display, **Figure 18-24.**

Always refer to the service manual for detailed instructions. Procedures vary from model to model, as well as from year to year. These methods will not work on vehicles equipped with OBD II.

Tech Tip!
Some older vehicles with on-board computers do *not* have on-board diagnostics. You must use conventional testing methods to pinpoint problems on these vehicles.

Reading Trouble Codes Without a Scan Tool

Reading trouble codes manually involves noting the computer output after the on-board diagnostics have been energized. There are several different ways that trouble codes can be read on older vehicles. The most typical methods include:

- Observing the check engine light as it flashes on and off.
- Noting an analog voltmeter's needle as it deflects back and forth.
- Watching a test light connected to the data link connector flash on and off.
- Reading the digital display in a climate control panel or driver's information center.
- Observing the LED display on the side of the ECM.

Reading the Flashing Check Engine Light

The check engine light displays trouble codes as it flashes on and off. Some codes are single-digit numbers and others are two-digit numbers. With single-digit codes, the number of pulses equals the code number. When there are multiple one-digit codes, there is a distinct pause between code numbers.

Reading a two-digit code is a bit more complex. If, for example, the light flashes once, pauses, and then flashes two more times, the trouble code would be 12 (1 pause 2). See **Figure 18-25**. If the check engine light blinks twice, pauses momentarily, and then blinks three more times, the trouble code would be 23 (2 pause 3). When there are multiple two-digit codes, there will be a relatively long pause between codes.

Reading Voltmeter Needle Deflections

An analog voltmeter code is read by counting the number of needle deflections between each pause. This is similar to the light flashes. However, the computer usually produces 5-volt pulses for the test meter.

RETRIEVING OBD I TROUBLE CODES (WITHOUT SCAN TOOL)

The three major auto makers use different procedures to make their car's on-board computer spit out trouble codes. The computer can actually detect if a sensor or actuator has failed or if a bad electrical connection has developed. This will help you know where to test for possible computer system problems.

The following is a summary of typical methods used to make an on-board computer produce these codes:

General Motors Corporation Trouble Codes

1. Locate diagnostic connector. It is usually under dash near fuse panel or steering column.
2. Use a jumper wire or paper clip to short across designated terminals in connector.
3. Watch engine light flash on and off in a Morse type code. Count number of flashes between each pause and note them. Three flashes, a pause, and two flashes would equal code 32.
4. Refer to trouble code chart in service manual for a explanation of code number.
5. Test suspected component or circuit with a digital VOM. Compare your test readings to factory specs.
6. Note that some GM cars require you to press two climate control buttons on dash at same time to enter self-diagnosis. Then, trouble code number will appear in dash. You would then need to find the same number in service manual trouble code chart.

Ford Motor Company Trouble Codes

1. Locate diagnostic connector. It is usually in engine compartment on firewall, fenderwall, or near engine intake manifold.
2. Connect an analog or needle type VOM to designated terminals in diagnostic connector.
3. Use a jumper wire to connect extra pigtail near connector to service-manual-designated terminal in connector.
4. Observe needle fluctuations on voltmeter as you did when watching engine light for a GM car. Count needle movements between each pause. Two needle movements, a pause and then six needle movements would equal code 26.
5. Refer to service manual trouble code chart to find out what number code means.
6. Use conventional testing methods and your VOM to pinpoint cause for problem.

Chrysler Corporation Trouble Codes

1. Chrysler provides a diagnostic connector in engine compartment on late model cars. However, connector is NOT needed to energize self-diagnosis. It is provided so a scanner-tester can be connected to system.
2. To trip trouble codes, simply turn ignition key on and off three times within five seconds. Turn key on, off, on, off, and then leave it ON.
3. Observe engine light flashing on and off. Count number of flashes between each pause. Three flashes, a pause, and then one flash would equal a trouble code of 31.
4. Refer to the service manual trouble code chart to find out which component or circuit is indicated by the trouble code.
5. Use conventional VOM tests to find the source of the trouble. Test the sensor or actuator and the wiring between the device and the computer.

Note! computer self-diagnosis systems and procedures can vary from the methods just described. Always refer to a factory service manual when in doubt!

Figure 18-25. A dash indicator light will normally glow if the computer detects a potential fault. This tells the driver and technician something is wrong. After energizing the computer's diagnostic mode, the dash light may flash on and off to produce a number code. Note how this code is read. (General Motors)

An example of a two-digit code would be if the needle deflected once, paused, and then deflected four more times. The first digit would be one and the second would be four. This trouble code would be 14. A few digital test meters have a bar graph that will show trouble code pulses. Look at **Figure 18-26.** However, most digital meters cannot read trouble codes.

Caution!
Use only a high-impedance (10 megohms or higher) test light or multimeter when testing computer circuits. A high current draw from a conventional test light could shorten electronic circuit life or even destroy delicate integrated circuits.

Reading Digital and LED Displays

Dash digital codes are read like scan tool codes. These codes are retrieved after pressing two dash buttons, usually climate control buttons, at the same time. The climate control or temperature readout will then show any trouble codes.

An LED trouble code is produced by indicator lights on the side of the computer. This is a less common method to display computer trouble codes. **Figure 18-27** summarizes how to use the LED trouble code.

Trouble Code Charts

A trouble code chart in the service manual will explain what each trouble code number means, **Figure 18-28.** This will help you know where to start further tests on specific components.

Erasing Trouble Codes

Erasing trouble codes, also termed clearing diagnostic codes, removes the stored codes from computer memory after system repairs have been made. In most

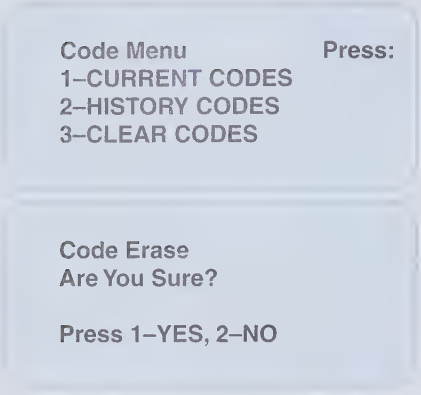
cases, codes will be automatically erased after 30-50 engine starts or warm-ups. However, codes should be erased after repairs are made to prevent a possible misdiagnosis by the next technician who works on the vehicle. There are various methods used to erase trouble codes from the computer:

- Use a scan tool to remove stored diagnostic codes from the on-board computer. This is the best way to remove old codes after repairs. In OBD II systems, the ECM may retain stored codes for several days without battery power. See **Figure 18-29.**



Code Menu Press:
1–CURRENT CODES
2–HISTORY CODES
3–CLEAR CODES

Code Erase
Are You Sure?

Press 1–YES, 2–NO

Figure 18-29. Using a scan tool is the fastest and easiest way to erase stored trouble codes. With most scan tools, simply choose the menu selection to clear codes and then press YES. (OTC)

- Disconnect the battery ground cable or strap. However, this will also erase the digital clock memory, all radio presets, and any adaptive strategy information from the computer.
- Unplug the fuse to the ECM. This will also erase all other information stored in the computer's temporary memory.

Caution!
Some auto manufacturers warn against unplugging or plugging in the computer harness connector with the ignition key on or the engine running. This could cause a voltage spike that could damage the computer.

After erasing trouble codes, reenergize the on-board diagnostics and check for diagnostic trouble codes. If no trouble codes are displayed, you have corrected the problem.

Tech Tip!
A memory saver, which consists of a small battery and alligator clips, can be connected across the battery terminals before disconnecting the battery. It will provide enough power to keep the clock, stereo, and computer from losing the information stored in their memories. When using a memory saver, turn off all accessories (radio, blower, etc.). The current drain from these devices, combined with even the smallest voltage drop, could cause electronic devices (computer, clock, radio, etc.) to lose their preprogrammed data.

Duff's Garage

Problem: Ms. Figuroa says that a light is glowing in the dash of her 1998 GMC pickup truck.

Diagnosis: Duff questions Ms. Figuroa as to the nature of the problem, but she says she has noticed nothing wrong other than the glowing light. Duff starts the vehicle and notes that the malfunction indicator light in the dash is glowing. He test drives the vehicle to try to find problem symptoms. He notices that the vehicle seems to miss slightly and lack normal power. He makes a note of his findings and turns the repair over to the shop's master technician.

After analyzing the symptoms, the technician connects a scan tool to the truck's data link connector. The scan tool readout indicates a problem with one of the oxygen sensors. The technician then performs pinpoint tests to verify the scan tool findings. As expected, the sensor's output is not within specifications. The technician removes the oxygen sensor using a special sensor socket. He notices that the sensor is covered with a heavy deposit of carbon. He then looks for possible causes of oxygen sensor contamination and discovers an extremely dirty air filter. The technician determines that the filter is restricting airflow into the engine, causing an overly rich mixture. The rich mixture most likely caused the sensor contamination.

Repair: The technician installs a new oxygen sensor and air filter. He then erases the stored trouble codes and rechecks the system for codes. No problems are found and the MIL light no longer glows. Upon returning the truck to Ms. Figuroa, the technician reminds her to change her air filter at recommended intervals to help prevent further problems.

Summary

- On-board diagnostics refers to a vehicle computer's ability to analyze the operation of its circuits and output data showing any problems.
- A scan tool is used to communicate with the vehicle's computers to retrieve trouble codes, display circuit and sensor electrical values, run tests, and give helpful hints for finding problem sources.

- OBD I and earlier on-board diagnostic systems could check only a limited number of items.
- OBD II systems are designed to more efficiently monitor the condition of hardware and software that affect emissions. New vehicle diagnostics detect part deterioration and not just complete part failure.
- If an unusual condition or electrical value is detected, the computer will turn on a malfunction indicator light (MIL) in the dash instrument panel or driver information center.
- Code conversion means the scan tool is programmed to automatically convert trouble codes into abbreviated words that explain what might be wrong without referring to a service manual.
- Diagnostic trouble codes (DTCs) are digital signals produced by the computer when an operating parameter is exceeded.
- Most scan tools come equipped with different program cartridges. A scan tool cartridge contains information about the specific make of vehicle to be scanned.
- The data link connector (DLC) is a multipin terminal for reading computer trouble codes or scanning problems.
- A scan tool snapshot or freeze frame is an instantaneous readout of operating parameters at the time of a malfunction.
- OBD II codes contain a letter and a four-digit number.
- The letter in all OBD II codes indicates the general function of the affected system.
- The first digit of the number in OBD II codes indicates whether the code is a standard trouble code or a nonuniform code.
- The second digit of the number in the OBD II code indicates the specific function of the system where the fault is located.
- The last two digits in the OBD II code refer to the specific fault designation.
- A wiggle test is done by moving wires and harness connectors while scanning to find soft failures.
- If you do not have a scan tool or are working on older computer-controlled vehicles, there are several other ways to activate computer on-board diagnostics to pull out trouble codes.

Review Questions—Chapter 18

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What is computer on-board diagnostics?
2. What is the first thing most technicians look at when diagnosing a computer system problem?
3. If an unusual condition or electrical value is detected, most computer systems will turn on a(n) _____ _____ _____.
4. List and summarize 17 types of problems that can affect computer system operation.
5. Only about _____ of all performance problems are caused by the computer, sensors, and actuators.
6. Give five locations for the data link connector.
7. Summarize the OBD II alpha-numeric diagnostic code.
8. Which of the following is a standardized OBD II code for a malfunction in the computer or auxiliary outputs?
   (A) P0605.
   (B) P1600.
   (C) P0141.
   (D) P0505.

9. Name the four general types of computer system failures.
10. A(n) _____ _____ is always present and a(n) _____ _____ is intermittent.
11. Explain key-on/engine-off diagnostics.
12. What is a wiggle test?
13. A non-OBD II car enters the shop with the computer warning light on. Technician A says that to trigger on-board diagnostics, you may have to connect a jumper wire across specified terminals in the diagnostic connector. Technician B says that to trigger on-board diagnostics, you may have to turn the ignition key on and off a specified number times. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
14. Explain several ways to read trouble codes without a scan tool.
15. What are trouble code charts?

ASE-Type Questions

1. Technician A says an automotive computer can scan its input and output circuits to detect incorrect voltage problems. Technician B says an automotive computer can scan its input and output circuits to detect an incorrect resistance problem. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
2. Technician A says if an automotive computer system detects an abnormal condition, the car's malfunction indicator light will normally be activated. Technician B says if an automotive computer system detects an abnormal condition, the car's low oil warning light will normally be activated. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
3. The malfunction indicator light in an OBD II system is flashing. Technician A says this means the problem could be damaging the catalytic converter. Technician B says that this simply indicates a soft problem. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
4. Technician A says a faulty actuator can affect the operation of an automotive computer system. Technician B says a leaking vacuum hose can affect the operation of an automotive computer system. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
5. Technician A says a spark plug misfire can affect the operation of an automotive computer system. Technician B says an automotive computer system is not affected by a spark plug misfire. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
6. An automobile has a small fuel tank leak. Technician A says this problem may activate the car's computer system "malfunction indicator light." Technician B says this type of problem has no effect on the car's computer system. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
7. Technician A says about 50% of all automotive engine performance problems are not caused by the computer system. Technician B says about 80% of all automotive engine performance problems are not caused by the computer system. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

8. Which of the following is a possible location for an automotive computer system's data link connector?
   (A) Under right side of dash.
   (B) Near the firewall in the engine compartment.
   (C) Under the center console.
   (D) All of the above.
9. When a trouble code number is looked up in a service manual, the trouble code chart says oxygen sensor. Technician A says to test the sensor and its circuit. Technician B says to replace the sensor. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Technician A says the term "hard failure" refers to an intermittent automotive computer problem. Technician B says the term "hard failure" refers to a constant automotive computer problem. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
11. A wiggle test is being performed on an automotive computer system. Technician A performs this test with the engine off and the ignition key off. Technician B performs this test with the engine off and the ignition key on. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
12. All of the following can normally be performed during an automotive computer system actuator self-test *except:*
    (A) open and close injectors.
    (B) fire the ignition coil.
    (C) operate the reed valve.
    (D) activate the idle speed motor.
13. Technician A says on certain models of automobiles, you can activate the computer's self-diagnostics by pushing two dash climate control buttons at the same time. Technician B says on certain models of automobiles, you can activate the computer's self-diagnostics by turning the ignition key on and off within a few seconds. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
14. Which of the following test instruments can be used to read automotive computer system trouble codes?
    (A) Test light.
    (B) Voltmeter.
    (C) Scan tool.
    (D) All of the above.
15. Trouble codes need to be erased from an OBD II computer system. Technician A wants to accomplish this by unplugging the ECM fuse. Technician B wants to accomplish this by using the shop's scan tool. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

Activities—Chapter 18

1. Demonstrate, on at least one vehicle, the proper method for using a scan tool.
2. Videotape a service technician using a scan tool to "check out" an engine. Ask the technician to explain each step as he or she performs the work. Show the completed tape to the class.

19 Computer System Service

After studying this chapter, you will be able to:

- Perform a visual inspection of the engine, its sensors, actuators, and the systems they monitor and control.
- Test sensors and their circuits.
- Remove and replace sensors.
- Test and replace actuators.
- Remove and replace a computer.
- Remove and replace a computer PROM.
- Program an EEPROM.
- Demonstrate safe working practices when servicing automotive computers.
- Correctly answer ASE certification test questions on servicing computer system components.

Since almost all vehicle systems now use computer components, you must have a basic knowledge of computer service before studying the remaining chapters in this text. Otherwise, you will not fully understand the chapters on fuel injection, ignition, and emissions systems.

This chapter will briefly summarize how to test computer components and circuits and help you develop the skills needed to verify *where problems are.*

After you have checked the computer for trouble codes, you can find the exact source of the problem by doing pinpoint tests. ***Pinpoint tests*** are more specific tests of individual components. The service manual will normally have charts that explain how to do each pinpoint test. It will show specific tests, as well as provide component electrical values and other critical information.

Remember that trouble codes only indicate the area of trouble and sometimes the type of problem, *not* what part or circuit is at fault. It is therefore imperative that you know how to do basic electrical tests on individual components.

Preliminary Visual Inspection

A ***preliminary visual inspection*** involves looking for signs of obvious trouble: loose wires, leaking vacuum hoses, part damage, etc. For example, if the trouble code says there is something wrong in the coolant temperature sensor circuit, you should check the sensor resistance and the wiring going to the sensor. You should also check the coolant level and the thermostat. A low coolant level or engine overheating could also set this code.

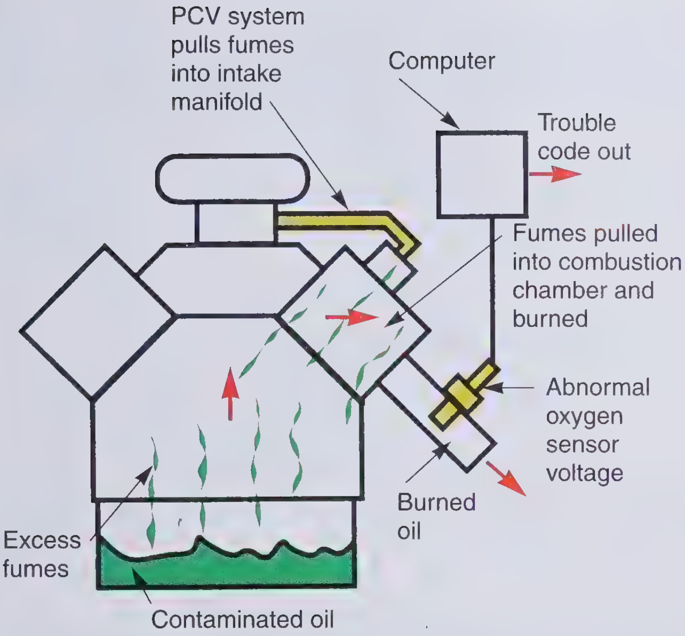
When there is a malfunction in a system, always remember that the cause is often something simple. It is easy for the untrained person to instantly think "computer problem" when an engine runs rough, fails to start properly, or exhibits some other performance problem.

For example, *contaminated engine oil* can trigger a computer trouble code, **Figure 19-1.** Fumes from the contaminated oil can be drawn into the engine's intake manifold from the crankcase. If these fumes are excessively strong, the oxygen sensor could be tricked into signaling a rich air-fuel mixture. The computer would then lean the mixture to compensate for the crankcase fumes. An oxygen sensor trouble code may be produced and, in some cases, an engine performance problem could result.

As this points out, it is critical that you check for conventional or simple problems *first.* Start checking for computer problems only after all the conventional causes have been eliminated.

KISS Principle

KISS is an acronym that could help you find the source of performance problems on a computer-controlled vehicle. ***KISS*** stands for *keep it simple, stupid.* This means you should start your troubleshooting with the simple checks and tests. Then, as the common causes



PCV system pulls fumes into intake manifold
Computer
Trouble code out
Fumes pulled into combustion chamber and burned
Abnormal oxygen sensor voltage
Burned oil
Excess fumes
Contaminated oil

Figure 19-1. This example shows that a trouble code can be tripped by factors other than a computer system problem. Contaminated engine oil can cause excess fumes to be pulled into the PCV system. When burned in the combustion chambers, the fumes could trick the computer into sensing that something is wrong with the oxygen sensor circuit.

are eliminated as the source of the problem, you will move to more complex tests.

Electrical Component Damage

Semiconductor devices, such as transistors and integrated circuits, are very easy to damage. They can be damaged by static electricity, voltage spikes, heat, and impact shocks. Here are some things to remember when working with semiconductor devices and their wiring:

- Arc welding can damage the on-board computers. If welding on the vehicle is necessary, remove all of the on-board computers. If this is not possible or too time-consuming, unplug their connectors and make sure the welder's lead is securely grounded.
- Never disconnect the battery cables while the engine is running. In the past, some technicians would do this to see if the alternator was working. This can destroy or weaken electronic circuits, causing failure in a short period of time.
- Do not disconnect or connect wiring, especially the computer wiring, with the ignition key on. This can cause a current surge that can damage the computer.
- Make sure you do not reverse the battery cable connections. This can destroy electronic components.
- Wear an anti-static wrist strap whenever you handle static-sensitive components (removable PROM chips for example) to protect them from damage.
- Use only high-impedance test lights and meters when checking electronic circuits or their wiring. A conventional test light or meter will draw too much current and destroy electrical components.
- Do not disconnect a scan tool from the data link connector while the ignition key is on. This could create a voltage spike that can damage the computer.

Computer System Circuit Problems

Almost all electrical-electronic problems are actually basic circuit problems. A ***basic circuit problem*** is caused by a problem in a circuit that increases or decreases current, resistance, or voltage. For example, a broken wire could stop current flow or a charging system problem could decrease output voltage and current flow.

Unfortunately, when a minor problem occurs in a complex circuit like a computer control system, it may *not* seem like a minor problem. For example, a poor electrical connection in a feed wire to a body ground may cause the computer system or one of the systems it controls to lose power. This can result in a shutdown of the fuel injection system, the emissions control system, the ignition system, or the entire vehicle.

You might think that any of these systems or the computer itself is at fault. Several systems could appear to have a problem. In reality, it is simply a poor electrical connection in one wire that is causing all the problems. It is important for an automotive technician to remain calm when diagnosing electrical problems. If analyzed properly, problems can usually be found and corrected easily.

Locating Computer Problems

The most difficult aspect of making computer system repairs is finding the source of the problem. To find the source of computer problems, you must ask yourself the following types of questions:

- What could be causing the specific symptoms? Mentally picture the parts in the circuit and how they function. Trace through the circuit while referencing a wiring diagram to find out which wires, connections, and components are in the circuit leading to potential trouble source.

- How many components are affected? If several components are *not* working, something close to a common power source or ground point is at fault. If only one or two sections of the circuit are faulty, begin your tests at those sections of the circuit.
- Is the problem always present or is it ***intermittent*** (only occurs under some conditions)? If the problem is intermittent, the conditions causing the problem will have to be simulated. For example, a loose electrical connection could open and close with vibration or movement. You might simulate driving conditions by wiggling wires and connectors in the circuit to make the problem occur.
- Is the problem's occurrence related to heat or cold? If it occurs only on a hot day or when the engine is warmed to full operating temperature, heat is related to the problem's occurrence. Electronic circuits (transistors in particular) are greatly affected by heat. In fact, too much heat can ruin an electronic component. You can use a heat gun to simulate the heat in an engine compartment.
- Is the problem's occurrence affected by moisture? If the trouble occurs only on wet or humid days, you have information to use when analyzing the source of a problem. In most cases, moisture cannot enter a sealed electronic component, but it may enter and affect the wire connections and any components exposed to the environment.

Stress testing refers to the use of heat, cold, or moisture to simulate extreme operating conditions of components, like spark plug wires, explained in a later chapter under spark plug wire leakage.

Sensor and Actuator Problems

As with other electrical and electronic components, sensors, actuators, and their circuits can develop opens, shorts, or abnormal resistance or voltage values. When your pinpoint tests find a problem, the sensor or actuator should be replaced or the circuit repaired.

In most cases, a scan tool is used to find the problem circuit and a digital multimeter is used to measure the resistance in the circuit and the actual sensor output or actuator input. Then, this value (voltage, resistance, current, or action) is compared to factory specifications. If the test value is too high or too low, you would know that the sensor or actuator is faulty and must be replaced.

The shop manual will also have a wiring diagram, or ***schematic,*** for the computer system. The diagram will show the color codes of the wires and the number of connectors that are used to feed signals from the sensors to the computer and from the computer to the actuators. This can be very helpful when servicing any computer system. The following paragraphs discuss the most frequent circuit problems.

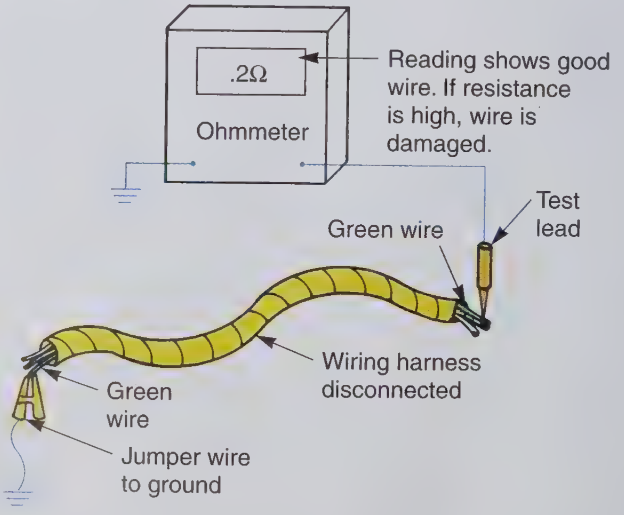
Poor Electrical Connections

Poor electrical connections are the most common cause of electrical-related problems in a computer system. Discussed in Chapter 18, a wiggle test will help find poor connections and intermittent problems. Always check electrical connections when diagnosing sensors and other electronic components. **Figure 19-2** shows how to test a wiring harness for opens or poor connections.

Poor electrical connections can be due to corroded terminals, loose terminal ends, burned terminals, chafed wires, and other problems. Dirt and moisture can get into connectors, causing high resistance. Any of these conditions can prevent a normal sensor signal from returning to the computer. They can also prevent the control current from reaching an actuator.

Vacuum Leaks

Vacuum leaks are frequently caused by deteriorated, broken, or loose vacuum hoses. Vacuum leaks often make



.2Ω
Ohmmeter
Reading shows good wire. If resistance is high, wire is damaged.
Test lead
Green wire
Wiring harness disconnected
Green wire
Jumper wire to ground

Figure 19-2. If you suspect a wire is broken inside the harness, this is an easy way to test the wire. Disconnect the wiring harness at both ends, and ground the suspect wire on one end. Then use an ohmmeter to check the wire's resistance. If the wire's resistance is high, the wire must be repaired, bypassed, or replaced.

a *hissing sound.* Some vacuum leaks can upset the operation of a computer system and cause a wide range of symptoms. Also, some engine sensors and actuators rely on engine vacuum for operation.

Always check for vacuum leaks when they could be causing a performance problem, **Figure 19-3.** For example, if the trouble code indicates a problem with the MAP (manifold absolute pressure) sensor, check the vacuum lines leading to the sensor. If there is a vacuum leak, the sensor cannot function normally. Also check the intake manifold gasket area, as this is a common location for vacuum leaks.

Air leaks after a mass airflow sensor can also cause problems. The sensor cannot measure the actual amount of air being drawn into the engine, and an incorrect air-fuel mixture will result.

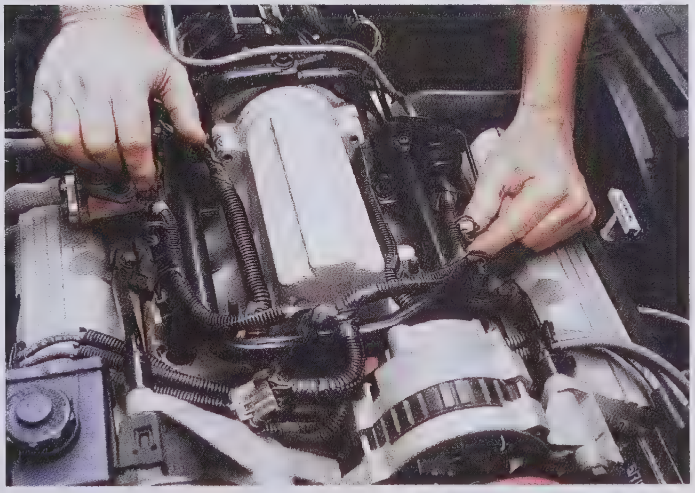


Figure 19-3. Always inspect the engine compartment for signs of trouble. A loose or corroded connection or a vacuum leak may be setting trouble codes or tricking the computer system.

Sensor Service

Sensor service involves testing and, if needed, replacing computer system sensors. Since sensor designs vary and some can be damaged by incorrect testing methods, it is important for you to know the most common ways of checking sensor values.

For testing purposes, you can classify sensors into one of two categories: passive sensors or active sensors. This will help you select a testing method.

As detailed in Chapter 17, a passive sensor varies its internal resistance as an operating condition changes. There are two common types of passive sensors: variable resistance sensors and switching sensors. The variable resistance sensor modifies a reference voltage that is sent from the computer. A switching sensor acts as either a conductor or an insulator, switching on and off with condition changes. Common passive sensors include the following:

- Intake air temperature sensors.
- Coolant temperature sensors.
- Throttle position sensors.
- Transmission linkage position sensors.
- EGR pintle position sensors.
- Manifold absolute pressure sensors.
- Fuel tank pressure sensors.
- Mass airflow sensors.
- Oil level sensors.
- Brake fluid level sensors.
- Suspension height sensors.

Active sensors, or voltage-generating sensors, produce a very weak internal voltage, which is sent to the computer for analysis. Typical active sensors include:

- Oxygen sensors.
- Engine speed sensors.
- Camshaft sensors.
- Crankshaft sensors.
- Vehicle speed sensors.
- Knock sensors.
- Solar sensors.

Each type of sensor needs a slightly different testing method. Refer to the service manual for exact sensor types and locations.

Testing Passive Sensors

Since passive sensors do *not* generate their own voltage, the computer must feed them a reference voltage. A passive sensor can change its internal resistance with a change in system or vehicle condition or operation. This resistance change modifies the reference voltage, which is interpreted and used by the computer to control the engine's various systems.

To test a passive sensor, either measure its internal resistance with an ohmmeter or measure the voltage drop across the sensor with its reference voltage applied. Depending on the sensor or manufacturer, both tests may be performed. You can also read computer data stream values with your scan tool. However, the scan tool cannot isolate the sensor, wiring, or computer for individual tests. Any unusual sensor readings by a scan tool should be verified using a multimeter.

Testing Variable Resistance Sensors

To test a variable resistance sensor with an ohmmeter:

1. Disconnect the sensor wires.
2. Connect the ohmmeter's test leads to the sensor terminals, **Figure 19-4A.**
3. Compare the ohmmeter reading to the manufacturer's specifications.

The sensor's resistance must be within factory specifications. For example, if you are testing a temperature sensor, connect an ohmmeter to the sensor terminals and then measure coolant temperature with a digital thermometer. Note the resistance readings at various coolant temperatures and compare these readings to service manual specifications.

If the sensor's resistance is within specifications, check for opens or shorts in the wires going to the sensor. If the wires are good, suspect the ECM. The service manual will give detailed instructions for testing the control module.

To check a variable resistance sensor with a voltmeter:

1. Connect the voltmeter in parallel with the sensor. Be sure to leave the computer wires connected to the sensor, **Figure 19-4B.**
2. Measure the voltage drop across the sensor with the computer reference voltage applied.
3. Compare your measurements to specifications.

Testing Switching Sensors

With a switching sensor, such as a power steering pressure switch, you can use an ohmmeter to check that the switch is opening and closing. As in **Figure 19-4C,** connect your ohmmeter and move the switch opened and closed. Your meter should register infinite ohms and then zero ohms. Replace the sensor if it is defective. You could also use a high impedance test light to quickly check the operation of a switching sensor.

Note that some auto manufacturers do not give resistance specifications for passive sensors, they only give voltage drops. You may have to use a test harness to connect the meter in parallel with the sensor. You can make or purchase this type of test harness.

Testing Reference Voltage

A reference voltage (typically *5 volts*) is fed to passive sensors. Then, when conditions and sensor resistance change, the amount of voltage flowing back to the computer also changes. The reference voltage is needed so that a signal returns to the computer.

To measure reference voltage to a passive sensor:

1. Disconnect the wires leading to the sensor.
2. Connect a digital voltmeter to the wires.
3. Turn the ignition key on and note your readings.
4. Compare your voltage readings to specifications.

Typically, the open circuit voltage should be about 5 volts. Refer to **Figure 19-5.**

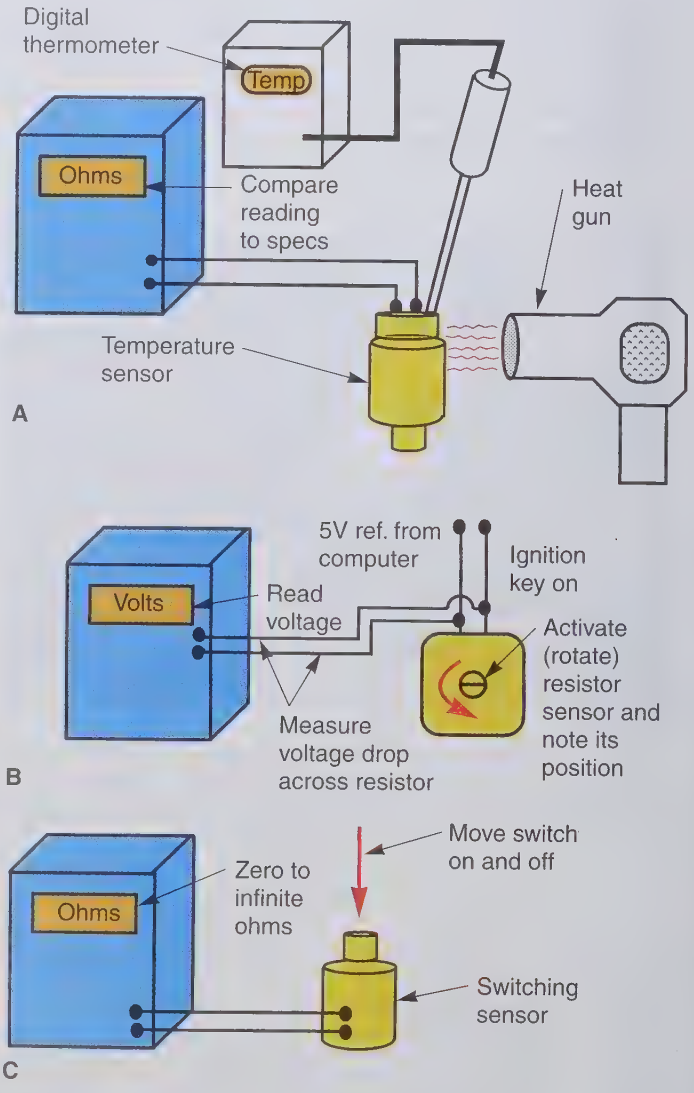

Figure 19-4. There are many ways to test passive sensors. A—An ohmmeter can be used to measure internal resistance. Some sensors can be heated with a heat gun while measuring resistance. A digital thermometer may also be used to compare actual temperature with sensor resistance. B—A voltmeter can be used if sensor specifications are only given as a voltage drop. The sensor must have reference voltage while testing occurs. C—Switching sensors may be tested with an ohmmeter or a high-impedance test light. The meter or light should show a change in condition when the switch is turned on and off.

If the reference voltage to the sensor is low, check the wiring harness for high resistance, as something is preventing the full reference voltage from reaching the sensor. Low reference voltage would cause a sensor to produce erroneous readings. It is possible for the reference voltage to be too high if a current-carrying wire is shorted into the circuit. High voltage may also be caused by a computer malfunction, but this is rare.

Testing Active Sensors

As mentioned, an active sensor produces its own voltage and sends it back to the computer. The voltage produced by an active sensor is very low, often under 1 volt. This makes sensor wiring harness continuity very critical. One poor electrical connection can keep the low voltage from returning to the computer.

Figure 19-6 shows several ways to test an active sensor. In **Figure 19-6A,** an ohmmeter is connected to a

C

Figure 19-6. Since an active sensor generates its own output signal, testing methods for active sensors are slightly different than those for passive sensors. A—Magnetic sensor internal coil resistance can be measured with an ohmmeter. B—An ac voltmeter can be used to check a magnetic sensor while it is operating. With the triggering device moving, an ac voltage signal should be generated. C—Sometimes it is recommended to connect a meter directly to the sensor. You can compare the operating sensor's output to specifications. Be sure to test the harness leading to the sensor.

common magnetic sensor. The ohmmeter will measure the resistance of the coil winding. Replace the sensor if the resistance is high or low.

In **Figure 19-6B,** an ac voltmeter is connected to a magnetic sensor. The trigger wheel must be rotated (engine cranked over, wheel or hub in an ABS system turned, etc.) to make the sensor generate voltage. A magnetic sensor should typically produce about 1.5-3 volts ac. A magnet can also be passed by a coil to make it produce a voltage.

In **Figure 19-6C,** a digital voltmeter is connected to an oxygen sensor. With the engine running in closed loop, the voltmeter should show the sensor's output voltage. If the output voltage from the sensor is low or high, the sensor may require replacement.

Tech Tip!
Whenever a sensor tests good, check the wiring leading to the sensor. Bad wiring may be blocking current flow back to the computer.

Figure 19-7 shows how to use small jumper wires to connect a meter to check a sensor while it is still functioning in the circuit. More advanced testing will be explained in later chapters.

Replacing Sensors

When replacing a sensor, there are several general rules you should remember:

- Always purchase an exact sensor replacement. Even though two sensors may look identical, their internal resistance or circuitry may be different. See **Figure 19-8.**
- Release the sensor connector properly. Most connectors have positive locks that must be released. If you damage the connector, intermittent problems may result from a loose connection.
- Use special tools as needed. Some sensors, such as oxygen sensors, require the use of a ***sensor socket.*** This socket has a deep pocket and a cutout that will fit over the sensor and any wires. Conventional deep sockets may not fit over the wiring or the sensor head.
- Use thread sealant sparingly. If the sensor seals a coolant, oil, or vacuum passage, do not use too much sealant.
- Use thread and engine sealants that are safe for oxygen sensors. Some sealants can poison the oxygen sensors.
- Tighten the sensor properly. Overtightening a sensor could damage it. Undertightening could cause leaks.
- Adjust the sensor, if needed. Some throttle position sensors require adjustment after installation.
- Scan for trouble codes after sensor replacement.

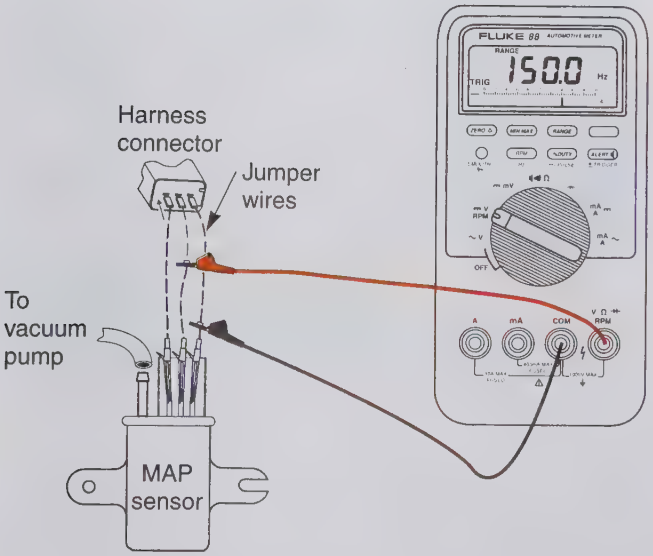

Figure 19-7. Small jumper wires are often used when measuring sensor circuit values. Make sure you do not short the jumper wires together or to ground. This test is used to measure the frequency signal in hertz from a manifold absolute pressure sensor. (Fluke)

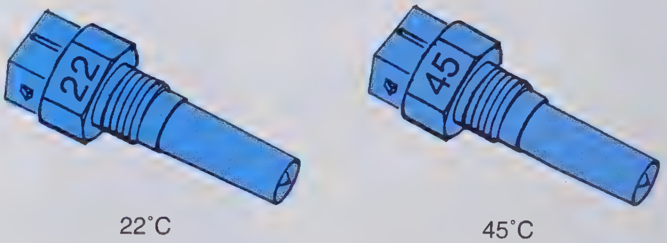

Figure 19-8. Always make sure the replacement sensor is same as the old one. These two temperature sensors look the same but have different temperature and resistance values. If the wrong one is installed, the vehicle may not function correctly. (Snap-On Tools)

Actuator Service

Actuator service involves testing the actuators for possible electrical or mechanical problems and replacing them, if necessary. If an actuator fails, the computer cannot control the engine and vehicle systems properly.

Testing Actuators

Since actuators are simply relays, solenoids, and motors, they are fairly easy to test. **Figure 19-9** shows several ways to test actuators.

Testing Servo Motors

In **Figure 19-9A**, a voltage source has been connected to a servo motor. The wiring harness to the motor has been disconnected. Jumper wires feed current directly to the motor. This is a simple way to check the operation of an electric or servo motor. If the motor begins to function with an external voltage source, you should test the wire harness leading to the motor.

Testing Solenoids

In **Figure 19-9B,** a voltage source is being used to check a solenoid. When jumper wires are connected to the vehicle's battery and the solenoid, the solenoid should operate. If the solenoid tests good, you should check the voltage coming to the solenoid through its harness.

An ohmmeter can also be used to test an actuator. You can use the meter to measure the internal resistance of the unit. By comparing resistance readings to specifications in the service manual, you can find out if the actuator must be replaced.

Testing Relays

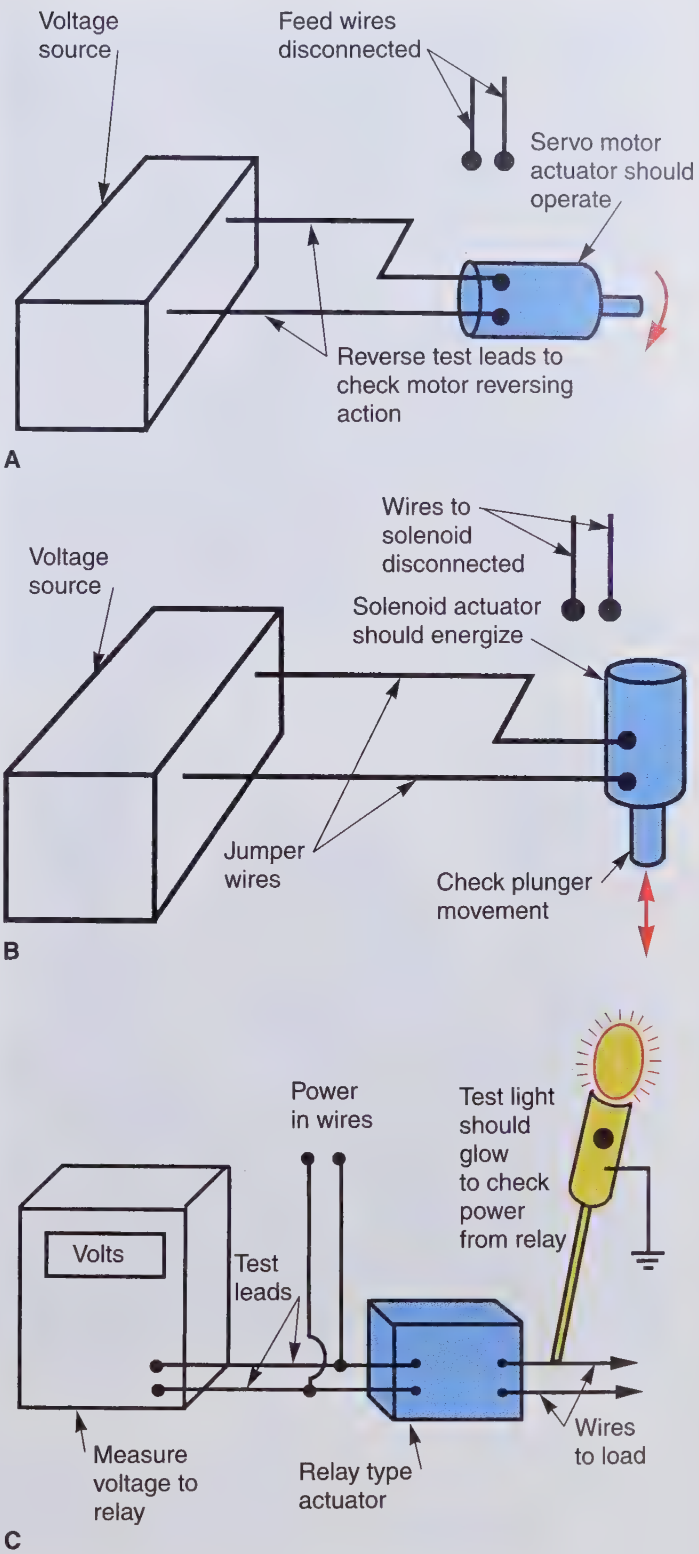
Figure 19-9C shows how to test a relay. Check the voltage entering the relay and the voltage leaving the relay. It is possible that voltage is applied to the relay but the relay points are not sending voltage out to the controlled device.

Since relays contain movable contact points, they are a common source of computer system problems. The scan tool may indicate a problem with the circuit containing the relay. However, you must test the relay to pinpoint the problem source.

Relays can be located almost anywhere on a vehicle: in the engine compartment, under the dash, under the seat, or in the trunk. The service manual will give exact locations. See **Figure 19-10.**

An integrated ***junction block*** encloses most or all of the vehicle's mechanical relays in a single housing. Some of the relays found in this block are the fuel pump relay, cooling fan relay, wide open throttle relay, air conditioning relay, and a host of others. The junction block is usually mounted in the engine compartment.

When testing a relay, refer to the service manual wiring diagrams for pin numbers and wire color codes. Special ***relay testers*** can be used to quickly test relay operation. They plug into the relay and test the unit automatically.



Voltage source
Feed wires disconnected
Servo motor actuator should operate
Reverse test leads to check motor reversing action
A
Voltage source
Wires to solenoid disconnected
Solenoid actuator should energize
Jumper wires
Check plunger movement
B

Measure voltage to relay
Relay type actuator
Wires to load
C

Figure 19-9. Actuator testing is straight-forward. It is similar to testing a conventional motor, relay, or solenoid. A—Voltage can be jumped to a servo motor. The motor should function when energized by the power source. B—A solenoid can also be tested in the same manner as a servo motor. C—A relay is slightly more complex to test. You must make sure there is an output when voltage is supplied to its input terminals. This can be done using a voltmeter or a high-impedance test light.

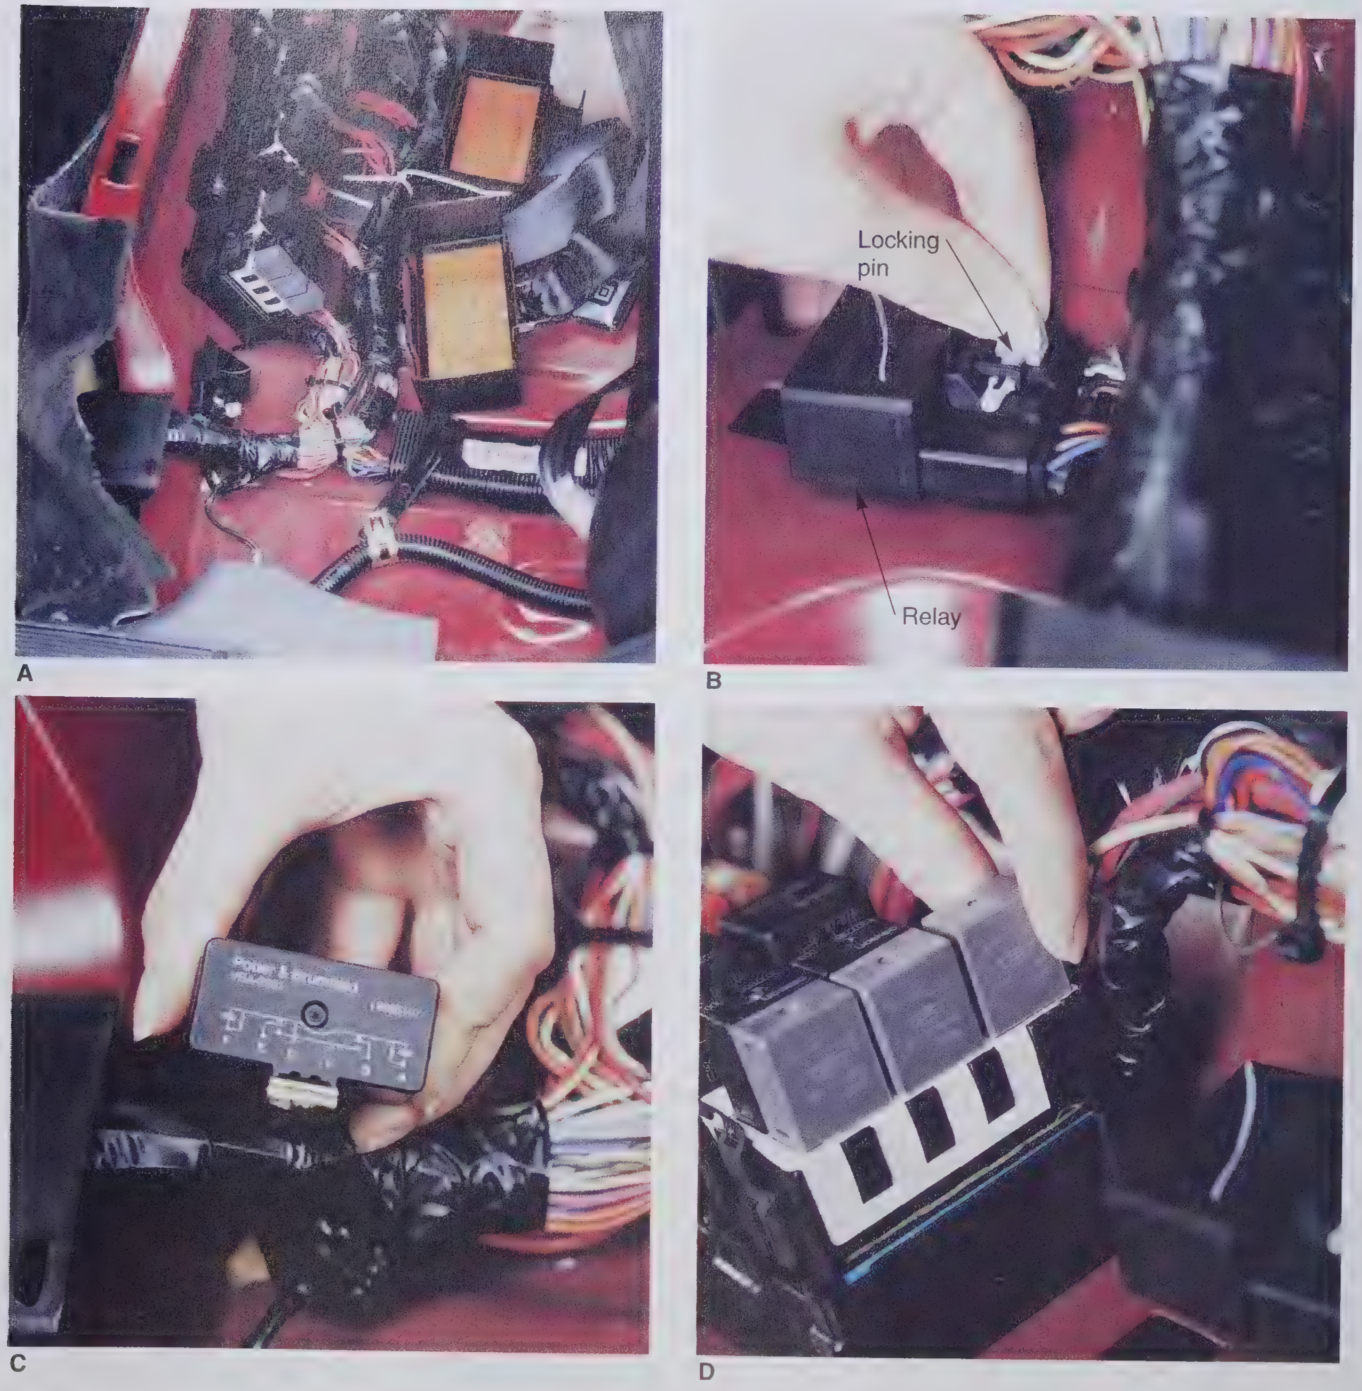

Figure 19-10. Relays have moving parts that can fail in service. Relays can be located almost anywhere on the vehicle. A—Technician has removed the rear seat cushion to gain access to the fuses and relays. B—This relay has a locking pin that must be removed before disconnecting the harness. C—Relays can have different internal construction. Make sure the replacement unit is identical to the original. D—The service manual will give relay locations for pinpoint testing and replacement.

For information on actuator service, refer to the index in this textbook. You can find instructions on testing fuel injectors, glow plugs, and more specialized actuators.

Replacing Actuators

Actuator replacement will vary with the type and location of the unit. Here are a few rules to follow when replacing an actuator.

- Do not damage the wire connectors when releasing them. They are made of plastic and will break if forced open improperly.
- Do not drop the actuator mounting screws during removal or installation. If a screws falls into an engine, major problems can occur.
- Make sure you have the correct replacement actuator before attempting installation.
- Check that the actuator is fully seated before tightening the mounting screws.
- Double check actuator operation after replacement.

Tech Tip!
Make sure you obtain the correct replacement relay. Two relays may look the same, but relays often have different internal construction.

Computer Service

Computer service involves replacing the computer. The computer is the last component to be suspected of being the problem source, only after all other potential sources of trouble have been eliminated. It is sometimes possible for an integrated circuit, transistor, or other electronic part in the computer to fail and upset system operation.

The diagnostic trouble code will tell you which computer or electronic control unit is having a problem. This information can help you find when the computer circuitry is at fault.

Measuring Computer Output

If the computer is not tested, in most cases, a defective computer is found through the process of eliminating the sensors, actuators, and related wiring as the cause of the problem. In the process of sensor and actuator testing, it was necessary for you to measure the computer's output. A ***computer output*** can be a reference voltage to a sensor or a supply voltage to an actuator.

Use a voltmeter to make sure the correct reference voltage is being sent to a sensor. Most computers produce a reference voltage of about 5 volts. If the reference voltage is not correct, check the wiring before condemning the computer. You can also measure voltage to make sure the correct voltage output is being fed to the actuators.

Each computer input and output passes through an individual metal terminal, or pin, which plugs into the vehicle wiring harness. ***Pin numbers*** identify the location and purpose (electrical value and internal connection) of each terminal in a computer wiring harness connector. You may have to probe computer terminal pins to find the source of complex problems. This will be discussed in Chapter 46.

Again, always refer to the service manual for exact procedures when testing a computer system. One wrong electrical connection can destroy the computer.

Caution!
Never use an ohmmeter to check a computer, as it will damage the computer's internal circuitry. If it is necessary to use an ohmmeter to check the continuity of a wire or circuit in the computer harness, disconnect all wiring harnesses from the computer before testing.

Saving Memory

Saving memory can be done by connecting a small battery (such as a 9-volt battery) across the two battery cables *before* the vehicle's battery is disconnected. This will provide enough power to keep the clock, stereo, and computer from losing the information stored in their memories. When using a memory saver, turn off all accessories (radio, blower, etc.). The current drain from these devices, combined with even the smallest voltage drop, could cause electronic devices (computer, clock, radio, etc.) to lose their preprogrammed data. You are still disconnecting the vehicle battery for safety. The smaller battery cannot produce enough current to cause an electrical fire or operate the starting system.

Computer Replacement

Before disconnecting the battery and removing the computer from the vehicle, you should scan the computer and obtain the PROM identification number or the EEPROM calibration number. This information is needed to check for updated PROMs that should be installed and calibration programs that should be downloaded to the new computer. External identification numbers are not always placed on the PROM.

When removing a computer, the ignition key should be off and the vehicle's negative battery cable disconnected. This will prevent voltage spikes from damaging the computer when the harness connectors are removed. Remove any shields or components necessary to access the computer. Unbolt the brackets holding the computer in place and unplug the computer connectors.

Identification information is usually stamped or printed on the computer. Use this data and the year, make, and model of vehicle to order the correct replacement computer. The VIN (vehicle identification number) may be helpful, as well.

Caution!
When handling computers, keep one hand on chassis ground and use the other to remove the component. This will prevent a static electrical charge from entering and damaging the electronic circuitry. If available, wear an anti-static wrist strap when working on computer circuits. Static electricity may not instantly ruin an electronic part, but it can reduce the part's useful service life from years to days.

PROM Service

Many computers use a PROM to store data for the specific make and model vehicle. In most cases, you must remove the PROM from the old computer and install it in the new computer.

Remove the cover over the PROM. Then, use a PROM tool to grasp and pull the PROM out of its socket. Most PROMs use a ***carrier***, which is a plastic housing that surrounds the outside of the integrated circuit chip. Avoid touching the PROM terminals with your fingers because the body oils on your hand could adversely affect the PROM's operation.

Before installing the PROM in the new computer, check that the pins (terminals) are straight. Check for the presence of ***reference marks*** (indentations or other markings to show how to reinstall the unit) on the PROM or the carrier. If you install a PROM backwards, it will usually require replacement because of physical damage.

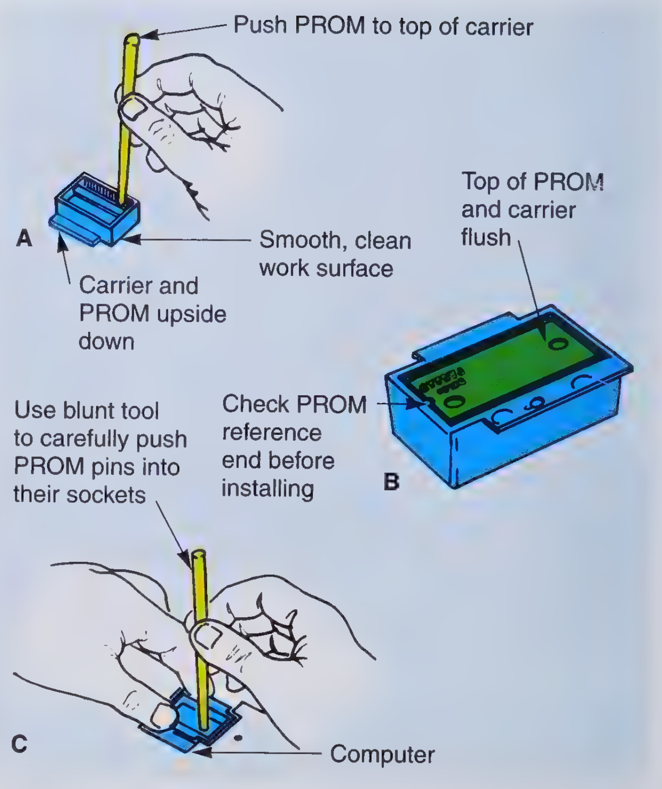
To install the PROM, install the carrier and PROM in the computer with the reference mark correctly positioned. First press down on the carrier only. Then, carefully press the PROM down into the computer. Press on each corner until the PROM is fully seated in its socket. If the PROM socket has locking tabs, make sure they are connected to the carrier housing, **Figure 19-11.**

After installing the PROM, install the access cover, connect the wiring harness to the computer, and install the computer into its mounts. Reconnect the battery, turn on the ignition, and activate self-diagnostics. As a final check of the computer and PROM, make sure no trouble codes are set. A code might be set if the PROM is not fully seated or a pin is bent over.

Updated PROMS

An ***updated PROM*** is a modified integrated circuit produced by the auto manufacturers to correct a driveability problem or improve a vehicle's performance. The old PROM is simply removed from the computer and replaced with the updated PROM.

Updated PROMs are produced to correct problems like surging, extended cranking periods, excessive emissions, cold and hot start problem, and unusual driveability problems that cannot be isolated to one system. If you are faced with a problem and cannot find the cause, check with the local dealership to find out if there are any updated PROMs for the vehicle that address the problem.



Push PROM to top of carrier
A
Smooth, clean work surface
Carrier and PROM upside down
Top of PROM and carrier flush
Use blunt tool to carefully push PROM pins into their sockets
Check PROM reference end before installing
B
C
Computer

Figure 19-11. Most PROMs use a carrier, which is a plastic case around the IC chip. The PROM from the old computer may have to be installed in the new computer. A—Before installing the PROM in the new computer, use a blunt tool to push the top of the chip flush with the top of the carrier. The IC pins should be sticking up and straight. B—Make sure reference marks are positioned correctly before installation. If you install the PROM backwards, it will be ruined. C—Touching only the carrier, position the PROM pins into the socket in the computer. Use a blunt tool or a small wooden dowel to carefully push the PROM into its socket. Push lightly on all corners until the PROM is fully seated. Do not press too hard. (General Motors)

Caution!
Installing a performance chip (aftermarket PROM chip that enhances engine performance) or a nonstock ECU will void the vehicle's warranty and may be a violation of federal law. Before installing any nonstock performance part, make sure the product is emissions legal or emissions certified for street use. All street-legal nonstock performance parts will be assigned an EO (executive order) exemption number by CARB (the California Air Resources Board). Products without this exemption number are not street legal.

EEPROM Programming Using Computerized Equipment

Most newer computers use Electrically Erasable Programmable Read Only Memory (EEPROM) or Flash Erasable Programmable Read Only Memory (FEPROM) chips that are permanently soldered to the circuit board. These chips must be programmed using electronic equipment. They are often reprogrammed to correct driveability and performance problems.

EEPROMs are programmed using a method referred to as flash programming. ***Flash programming*** may be performed by downloading the vehicle's information through a computer, a computerized diagnostic analyzer, or a scan tool. Actual programming details vary between manufacturers, but the basic procedure begins by placing the computer in the programming mode. One of three methods is used to program the computer:

- Direct programming using a service computer or computerized analyzer.
- Indirect programming using a scan tool and a computer or computerized analyzer.
- Remote programming with the computer off the vehicle.

Direct Programming

Direct programming is the fastest and simplest method. The new information is downloaded by attaching a shop recalibration device (usually a computer or computerized analyzer) directly to the data link connector. The erasure and programming is done by accessing the programming menu and following the instructions as prompted by the computer. Then, the vehicle's operating information and parameters are entered into the vehicle's computer through the connector.

Indirect Programming

To perform ***indirect programming,*** the proper scan tool must be available to connect to the programming computer and to the vehicle, as well as to reset some computer-controlled vehicle systems after programming. The programming computer may resemble the personal computer (PC) used in the home, or it may be a computerized analyzer like the one used for direct programming.

In this type of programming, the vehicle information is downloaded from the programming computer into the scan tool. The information is then downloaded from the scan tool into the vehicle's computer. The scan tool menu is accessed using the keypad. Most scan tools will use a high-capacity generic program cartridge to store the information. Some newer scan tools have enough fixed memory to hold the information and, therefore, do not use a separate program cartridge. In either case, follow the manufacturer's procedure as prompted.

Remote Programming

Remote programming is done with the vehicle's computer removed from the vehicle. This procedure is used when changes need to be made through a direct modem connection to a manufacturer's database computer. It can also be done in cases where direct or indirect programming is not practical or possible. Since special connectors and tools are required for this type of programming, this procedure is done only at new vehicle dealerships.

EEPROM Programming Procedure

To begin programming the EEPROM-equipped computer, make sure that the vehicle's battery is fully charged. Recharge the battery if necessary. Do not charge the battery during the programming procedure, as damage to the computer will result. Connect the programming computer or scan tool to the data link connector. Make any other vehicle connections as needed before proceeding with the programming sequence.

Caution!

Do not disconnect the scan tool or programming computer from the data link connector during the programming sequence. Doing so will damage the vehicle's computer.

To start the programming sequence, the programming computer or scan tool prompt may ask you to enter the engine type, vehicle type, and vehicle identification number (VIN) in a specific sequence. Once the vehicle information is entered, go to the programming software and follow the directions as prompted.

Depending on the manufacturer, it may be necessary to turn the ignition switch on or off during the connection and programming procedure. Double check any instructions on ignition switch position before making any connections or beginning the programming procedure. The next step is to determine the type of programming that is needed.

Programming a New Computer

If a new computer is being installed, program only that computer. In many cases, other on-board computers can be accessed and programmed using the data link connector. While most computers have internal circuitry that protects them from accidental programming, be careful not to program the wrong computer. Do not attempt to program a new computer with information from the old computer or a computer from another vehicle. Any attempt to do this will set a failed programming sequence code in the new computer's memory.

Tech Tip!

In some cases, an erasure may need to be performed on a new computer before initial programming can take place.

Reprogramming Computers

Before reprogramming a vehicle's computer, determine the date that the current programming was downloaded or check the program's calibration number. If the current program is the latest version, no further actions are required. If the latest program has not been downloaded, proceed with the reprogramming sequence.

Before reprogramming most computers, you must first erase the existing information. After this step is complete, select the updated calibration information from the programming computer or scan tool menu. Then download the new information into the computer. On some systems, the erasure step is not necessary since the programming computer or scan tool will erase or overwrite the old information as it loads the new program into the computer.

Tech Tip!

If the computer does not accept the new program or cannot be programmed, check all connections first. Ensure that the correct computer is being reprogrammed with the proper information and that all procedures are being followed. If the computer still cannot be programmed, it may need to be replaced.

Allow sufficient time for the programming to take place. Monitor the computer or scan tool to determine when the programming sequence is complete. Do not touch any connections until you are sure the programming sequence is complete. After programming is completed, turn the ignition switch to the position called for and disconnect the computer or scan tool. Then, use a scan tool to check the computer and control system operation. While doing this, make sure you have installed the proper program into the computer by checking the program calibration number.

Computer Relearn Procedures

After being serviced, the computer system may have to go through a relearn procedure. A ***relearn procedure*** is a period of vehicle operation during which the computer system adapts to new components and programming information. The computer must receive inputs to formulate adaptive strategy to set some of its output parameters. The relearn procedure can often be done by simply driving the vehicle for several minutes. Some vehicles require a specific relearn procedure. Always check the manufacturer's service literature for exact relearn methods. In a few cases, sensors or actuators may have to be manually adjusted using a scan tool.

Duff's Garage

Problem: Mr. Hayes brought his 1993 Firebird into the shop, complaining of a hesitation, or stumble, when he accelerates the vehicle from a standing start.

Diagnosis: Duff test drives the vehicle to double-check the symptoms and to observe engine performance. He immediately notices a hesitation during acceleration. The vehicle seems to operate normally at cruising speed.

Once back at the shop, Duff opens the hood and inspects the engine compartment for obvious problems, such as loose connections, split vacuum hoses, etc. Although he does not notice any obvious problems, he does hear a slight hissing sound that seems to be coming from somewhere near the top of the engine. He turns the job over to one of his technicians, who checks the vehicle for trouble codes but finds none.

Based on Duff's initial inspection, the technician uses a piece of vacuum hose to help locate the source of the hissing sound. He holds one end of the hose to his ear while moving the other end around the engine compartment in an attempt to pinpoint the hissing sound. The sound seems to be loudest near the engine's MAP sensor.

Upon further inspection, the technician finds a hairline crack in the end of the vacuum hose going to the sensor. The crack opens up as the engine vibrates during acceleration. This causes a vacuum leak during acceleration. The crack closes up once the vehicle reaches cruising speed, sealing the leak. Even during acceleration, the vacuum leak is too small to set a trouble code.

Repair: The technician replaces the vacuum hose leading to the MAP sensor. He then inspects the other hoses for cracks and hardened ends. In all, he replaces three vacuum hoses. He then test drives the vehicle to make sure the repair fixed the problem before releasing the vehicle to the customer.

Summary

- Pinpoint tests are specific tests of individual components. They are completed after scanning for trouble codes.
- A preliminary inspection involves looking for signs of obvious trouble: loose wires, leaking vacuum hoses, part damage, etc.
- Semiconductors are very easy to damage. They can be damaged by static electricity, voltage spikes, heat, and impact shocks.
- Stress testing refers to the use of heat, cold, or moisture to simulate extreme operating conditions of components, like an electronic control unit.
- Poor electrical connections are the most common cause of electrical-related problems in a computer system.
- Vacuum leaks are frequently caused by deteriorated, broken, or loose vacuum hoses. Vacuum leaks often make a *hissing sound.*
- A reference voltage (typically *5 volts*) is fed to switching and variable resistance type sensors.
- Sensor sockets have a deep pocket and cutout from any sensor pigtail (wires).
- Since they contain movable contact points, relays are a common source of computer system problems.
- Computer service usually involves a few tests and computer replacement if needed.
- Some computers use the old PROM (memory chip) during computer replacement, since it stores data for the specific make and model vehicle.

Review Questions—Chapter 19

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What should you look for during a preliminary inspection of a computer system?
2. Explain five questions you should ask yourself when analyzing computer system problems.
3. How can a vacuum leak upset the operation of a computer system?
4. An engine runs poorly only when cold. Symptoms and a trouble code indicates a problem with the engine coolant temperature sensor. Technician A says to measure the engine coolant temperature sensor's resistance with a digital ohmmeter while measuring coolant temperature with a digital thermometer. Technician B says to measure the sensor's ac voltage output while measuring its temperature with a digital thermometer. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
5. How do you check sensor reference voltage?
6. Explain three ways to test an active sensor.
7. Describe three ways to test an actuator.
8. Relays are a common source of problems in a modern computer system. True or false?
9. How do you save computer memory?
10. The computer must be removed from a late-model vehicle. Technician A says to keep one hand on chassis ground when handling the computer. Technician B says to wear an anti-static wrist strap when handling the computer. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.

ASE-Type Questions

1. Technician A says automotive computer system trouble codes are used to detect faulty components in the system. Technician B says automotive computer system trouble codes are used to indicate the general area of trouble in a computer system. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.

2. A trouble code is triggered in an automotive computer system. Technician A says fuel-contaminated engine oil could possibly trigger this trouble code. Technician B says fuel-contaminated engine oil has no effect on computer system operation. Who is right?
   - *(A) A only.*
   - *(B) B only.*
   - *(C) Both A and B.*
   - *(D) Neither A nor B.*
3. Technician A says a basic circuit problem is caused by something in the circuit that increases or decreases current. Technician B says a basic circuit problem is caused by something in the circuit that increases or decreases resistance. Who is right?
   - *(A) A only.*
   - *(B) B only.*
   - *(C) Both A and B.*
   - *(D) Neither A nor B.*
4. A scan tool indicates a problem with the MAP sensor. Technician A says you should check the operating condition of the MAP sensor. Technician B says you should check for poor electrical connections in the system. Who is right?
   - *(A) A only.*
   - *(B) B only.*
   - *(C) Both A and B.*
   - *(D) Neither A nor B.*
5. Technician A says a passive automotive sensor is capable of generating its own voltage. Technician B says a passive automotive sensor is not capable of generating its own voltage. Who is right?
   - *(A) A only.*
   - *(B) B only.*
   - *(C) Both A and B.*
   - *(D) Neither A nor B.*
6. Which of the following is not considered a passive automotive computer sensor?
   - *(A) Intake air temperature sensor.*
   - *(B) EGR sensor.*
   - *(C) Oxygen sensor.*
   - *(D) Mass airflow sensor.*
7. Technician A says a reference voltage of about 12 volts is normally required for an automotive variable resistance type sensor to operate properly. Technician B says a reference voltage of about 5 volts is normally required for an automotive variable resistance type sensor to operate properly. Who is right?
   - *(A) A only.*
   - *(B) B only.*
   - *(C) Both A and B.*
   - *(D) Neither A nor B.*
8. A trouble code shows a problem with an active sensor. Technician A says the voltage produced by an active sensor is very low, often under 1 volt. This makes sensor output and wiring harness continuity very critical. Technician B says that active sensor signals are just as strong as passive sensor signals. Who is right?
   - *(A) A only.*
   - *(B) B only.*
   - *(C) Both A and B.*
   - *(D) Neither A nor B.*
9. An automobile's oxygen sensor output needs to be checked. Technician A uses a digital voltmeter to check this sensor's output. Technician B uses an analog ohmmeter to check this sensor's output. Who is right?
   - *(A) A only.*
   - *(B) B only.*
   - *(C) Both A and B.*
   - *(D) Neither A nor B.*
10. An oxygen sensor tested faulty and must be replaced. Technician A says to avoid using sealer because it can contaminate the new sensor. Technician B says to use a sensor socket to prevent sensor damage. Who is right?
    - *(A) A only.*
    - *(B) B only.*
    - *(C) Both A and B.*
    - *(D) Neither A nor B.*

Activities—Chapter 19

1. Describe and sketch the procedure you would use to test a temperature sensor for proper operation.
2. Demonstrate two methods of checking a knock sensor—with a multimeter and by manual tapping.
3. Obtain an unserviceable vehicle computer with a removable PROM from a junkyard or other source and use it to practice removing and replacing the PROM.

Computer System Sensor and Actuator Diagnosis

Condition	Possible Causes	Correction
Hard starting.	1. Faulty coolant temperature sensor. 2. Defective intake air temperature sensor. 3. Maladjusted or defective throttle position sensor. 4. Faulty crankshaft position sensor. 5. Faulty manifold absolute pressure sensor. 6. Bad mass airflow sensor. 7. Faulty idle speed motor. 8. Bad fuel injectors.	Test components and related circuitry. Service or replace as necessary.
Engine stalling.	1. Faulty coolant temperature sensor. 2. Defective intake air temperature sensor. 3. Maladjusted or defective throttle position sensor. 4. Faulty crankshaft position sensor. 5. Faulty manifold absolute pressure sensor. 6. Bad mass airflow sensor. 7. Faulty idle speed motor. 8. Bad fuel injectors.	Test components and related circuitry. Service or replace as necessary.
Rough idle or surging.	1. Faulty coolant temperature sensor. 2. Defective intake air temperature sensor. 3. Maladjusted or defective throttle position sensor. 4. Faulty crankshaft position sensor. 5. Faulty manifold absolute pressure sensor. 6. Bad mass airflow sensor. 7. Faulty idle speed motor. 8. Bad fuel injectors.	Test components and related circuitry. Service or replace as necessary.
Erratic idle speeds.	1. Maladjusted or defective throttle position sensor. 2. Faulty crankshaft position sensor. 3. Bad idle speed motor.	Test components and related circuitry. Service or replace as necessary.
Cold engine warm-up problems.	1. Faulty coolant temperature sensor. 2. Faulty intake air temperature sensor. 3. Faulty manifold absolute pressure sensor. 4. Bad mass airflow sensor. 5. Bad idle speed motor.	Test components and related circuitry. Service or replace as necessary.
Engine hesitation.	1. Faulty coolant temperature sensor. 2. Faulty air temperature sensor. 3. Maladjusted or defective throttle position sensor. 4. Faulty EGR position sensor. 5. 25. Carburetor Diagnosis, Service, Repair
26. Diesel Injection Fundamentals
27. Diesel Injection Diagnosis, Service, Repair
28. Exhaust Systems, Turbochargers, and Superchargers

Today's fuel systems must meter a precise amount of fuel into the engine under a wide range of constantly changing operating conditions. The fuel system has the important job of optimizing engine performance while keeping fuel consumption and emissions to a minimum. This is no easy task!

This section will explain modern fuel systems in detail. Chapters 20 and 21 cover fuels, fuel tanks, fuel pumps, and fuel filters. Chapters 22 and 23 describe the operation and service of electronic fuel injection, the most common type of fuel system. Chapters 24 and 25 provide a brief overview of carburetor operation and repair, since millions of these devices are still in use today. Chapters 26–28 explain the operation and repair of diesel injection, exhaust systems, turbochargers, and superchargers.

The information in this section will help you pass ASE Test A6, *Electrical/Electronic Systems,* and Test A8, *Engine Performance.*

20 Automotive Fuels, Gasoline and Diesel Combustion

After studying this chapter, you will be able to:

- Summarize how crude oil is converted into gasoline, diesel fuel, liquefied petroleum gas, and other products.
- Describe properties of gasoline and diesel fuel.
- Explain octane and octane ratings.
- Describe normal and abnormal combustion of gasoline and diesel fuel.
- Summarize the properties of alternative fuels.
- Correctly answer ASE certification test questions on automotive fuels and combustion.

An automotive engine burns ***fuel*** as a source of energy. Various types of fuel will burn in an engine: gasoline, diesel fuel, gasohol, alcohol, liquefied petroleum gas, and other alternative fuels.

An automotive technician must understand how fuel burns inside an engine. ***Combustion*** (burning) is a primary factor controlling fuel economy, power, emissions, and engine service life.

Petroleum (Crude Oil)

Crude oil, or ***petroleum***, is oil taken directly out of the ground. It is used to make gasoline, diesel fuel, liquefied petroleum gas, and many nonfuel materials (asphalt, motor oil, etc.). **Figure 20-1** shows some of the products made from crude oil.

Natural crude oil is a mixture of *semisolids* (neither solid nor liquid), liquids, and gases. Chemically, crude oil consists of highly flammable hydrocarbons.

Hydrocarbons are chemical mixtures of about 12% hydrogen (flammable gas vapor) and 82% carbon (heavy, black solid). Crude oil also contains sulfur, nitrogen, metals, and saltwater. These elements must be removed.

Processing Crude Oil

Crude oil deposits are contained inside the earth. Oil companies perform ***exploration tests*** (seismic studies, surface mapping, and test drilling) to find oil. After determining where oil might be located, a drill crew bores a hole thousands of feet into the ground. A huge steel derrick is used for the drilling operation. It has a cutting bit capable of passing through dirt, sand, and rock. See **Figure 20-2.**

Once the oil deposit has been reached, the oil is pumped to the surface. Then, the oil is sent to the refinery. The ***refinery*** converts the crude oil into more useful substances.

Distillation is the first conversion process. During distillation, a ***fractionating tower*** is used to break the crude oil down into different parts, or fractions (LPG, gasoline, kerosene, fuel oil, and lubricating oils). Look at **Figure 20-3.** After distillation, other processes purify these products.

Gasoline

Gasoline is the most common type of automotive fuel. It is an abundant and highly flammable part of crude oil. Extra chemicals, called additives (detergents, antioxidants, etc.), are mixed into gasoline to improve its operating characteristics.

Antiknock additives slow down the burning of gasoline. This helps prevent ***engine ping,*** or ***knock*** (knocking sound produced by abnormal, rapid combustion).

Gasoline Octane Ratings

The ***octane rating*** of gasoline is a measurement of the fuel's ability to resist knock or ping. A high octane rating indicates the fuel will *not* knock or ping easily. High-octane gasoline should be used in high-compression engines and turbocharged engines. Low-octane gasoline is suitable for low-compression engines.

Octane numbers give the antiknock value of gasoline. Gasoline with a high octane number (91, for example) will resist knock and ping better than gasoline with a low octane number (87, for example).

Octane numbers are given on the gas station pump, **Figure 20-4.** Automakers recommend octane ratings of fuel for their engines. The owner's manual will give the octane number recommended for the car's engine. Use a fuel with an octane number as high as or higher than the automaker's recommendations. **Figure 20-5** summarizes several factors that control engine octane requirements.

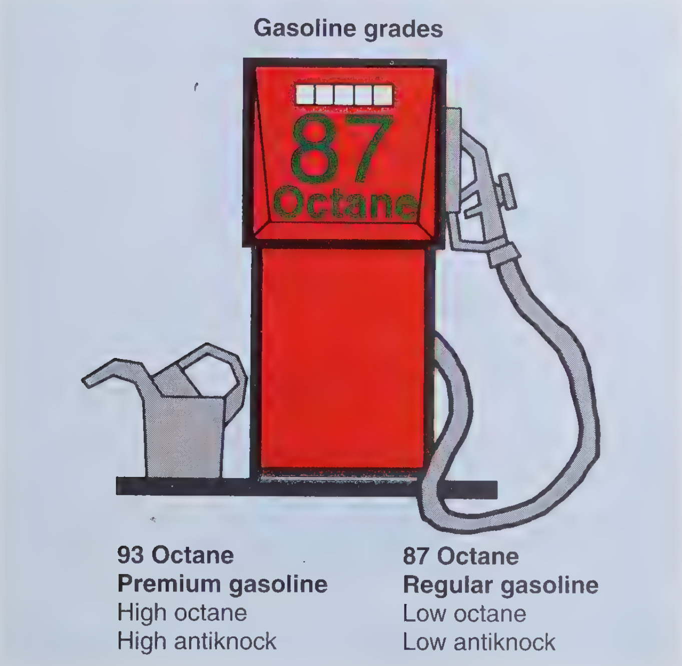

Figure 20-4. The gasoline grade indicates the antiknock value of gasoline.

In the past, tetraethyl lead (a heavy metal) was used to increase the octane rating of gasoline. It was phased out because it posed a health hazard.

Octane enhancers, or ***oxygenates***, are now used as blending components in gasoline to increase octane levels and reduce engine knock. Oxygenates are alcohols that are made up of hydrogen, carbon, and oxygen. Examples of octane enhancers include toluene, ethanol, and MTBE.

Gasoline Combustion

For gasoline (or any other fuel) to burn properly, it must be mixed with the right amount of air. The mixture must then be compressed and ignited. The resulting combustion produces heat, expansion of gases, and pressure. The pressure pushes down on the piston to rotate the crankshaft. Refer to **Figure 20-6.**

Normal Gasoline Combustion

Normal gasoline combustion occurs when the spark plug ignites the fuel and burning progresses smoothly through the fuel mixture. Maximum cylinder pressure should be produced a few degrees of crank rotation after piston TDC on the power stroke. **Figure 20-7** illustrates normal gasoline combustion:

A— A spark at the spark plug starts the fuel burning. A small ball of flame forms around the tip of the plug. The piston is moving up in the cylinder, compressing the fuel mixture.

Octane requirement factors

Octane number requirement tends to go *up* when:

1. Ignition timing is advanced.
2. Air density rises due to supercharging, a larger throttle opening, or higher barometric pressures.
3. Humidity or moisture content of air decreases.
4. Inlet air temperature goes up.
5. Lean fuel-air ratios.
6. Compression ratio is increased.
7. Coolant temperature is raised.
8. Antifreeze (glycol) engine coolant is used.
9. Combustion chamber design provides little or no quench area.
10. Vehicle weight is increased.
11. Engine loading is increased, such as when climbing a grade, pulling a trailer, or increasing wind grade, or increasing wind resistance with a car-top carrier.

Octane number requirement tends to go *down* when:

1. Car is operated at higher altitudes (lower barometric pressure).
2. Fuel-air ratio is richer or leaner than that producing maxium knock.
3. Spark plug location in combustion chamber provides shortest path of flame travel.
4. Combustion chamber design gives maximum turbulence of fuel-air charge.
5. Compression ratio is lowered.
6. Exhaust gas recycle system operates at part-throttle.
7. Ignition timing retard devices are used.
8. Humidity of the air increases.
9. Ignition timing is retarded.
10. Inlet air temperature is decreased.
11. Reduced engine loads are employed.

Figure 20-5. Various factors that control octane requirements. (Ethyl Corp.)

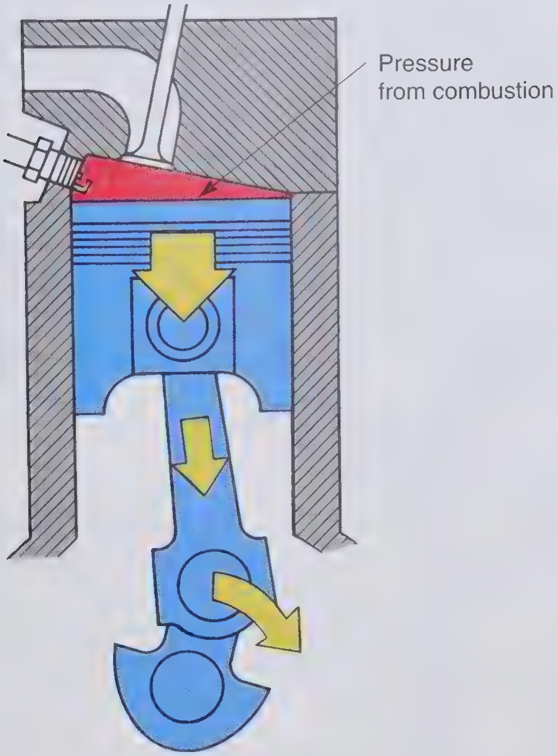

Figure 20-6. Combustion produces heat. Heat causes gases to expand. Expansion causes pressure. Pressure pushes the piston down on power stroke. (Ford)

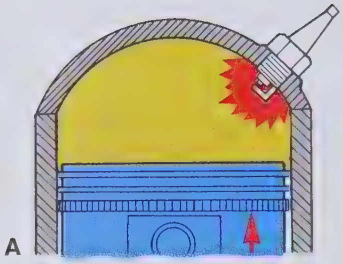
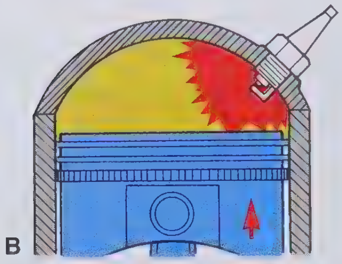
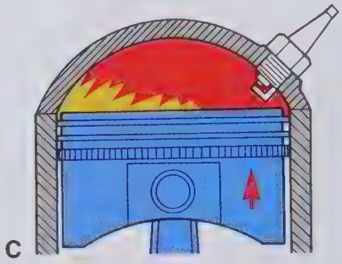


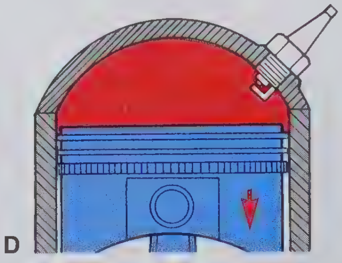
Spark occurs, ball of flame forms around electrodes.



Flame front spreads smoothly while piston nears TDC.



Piston has reached TDC and flame is "shooting" through chamber, forming heat.



Combustion pressure is maximum and piston is a few degrees down in cylinder.

Figure 20-7. Normal combustion. A single flame moves smoothly through the air-fuel mixture.

B— The flame spreads faster and moves about halfway through the mixture. Generally, the flame is moving evenly through the fuel mixture. The piston is nearing TDC, causing increased pressure.

C— The piston reaches TDC. The flame picks up more speed.

D— The flame shoots out to consume the rest of the fuel in the chamber. Combustion is complete with the piston only a short distance down in the cylinder.

Normal combustion only takes about 3/1000 of a second. This is much slower than an explosion. Dynamite explodes in about 1/50,000 of a second. Under some undesirable conditions, however, gasoline can burn too quickly, making part of combustion like an explosion. This is detailed later.

Air-Fuel Mixture

For proper combustion and engine performance, the correct amounts of air and fuel must be mixed. If too much fuel or too much air is used, engine power, fuel economy, and efficiency will suffer.

A ***stoichiometric fuel mixture*** is a chemically correct air-fuel mixture. For gasoline, it is a mixture ratio of 14.7:1 (14.7 parts air to 1 part fuel, by weight). Under constant engine conditions, this ratio helps ensure that all the fuel is burned during combustion.

As you will learn in later chapters, the conditions in an engine are not always ideal. The fuel system must change the air-fuel ratio with changes in engine operating conditions.

Lean and Rich Air-Fuel Mixture

A ***lean air-fuel mixture*** contains a large amount of air compared to fuel. Look at **Figure 20-8A.** For gasoline, 20:1 is a very lean mixture.

A ***rich air-fuel mixture*** is the opposite of a lean mixture; more fuel is mixed with the air. For gasoline, 8:1 (8 parts air to one part fuel) is a very rich fuel mixture. Refer to **Figure 20-8B.**

A slightly lean mixture is desirable for high gas mileage and low exhaust emissions. Extra air in the cylinder ensures that all the fuel is burned. Too lean a mixture, however, can cause poor engine performance (lack of power, missing, and even engine damage).

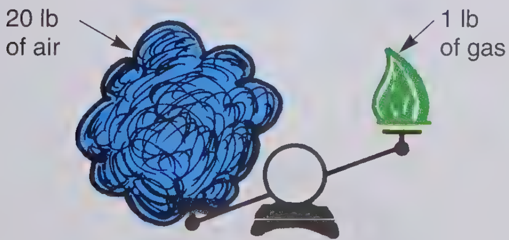
A slightly rich mixture tends to increase engine power. However, it also increases fuel consumption and exhaust emissions. An over-rich mixture will reduce engine power, foul spark plugs, and cause incomplete burning (black smoke at engine exhaust).

Abnormal Combustion

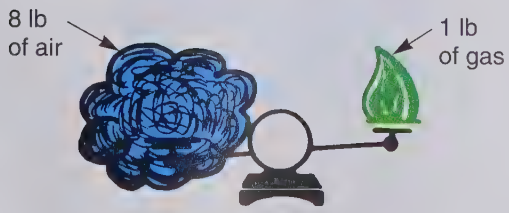
Abnormal combustion occurs when the flame does not spread evenly and smoothly through the combustion chamber. The lean air-fuel mixtures, high operating temperatures, and low-octane fuels of today make abnormal combustion a problem.

Detonation

Detonation results when part of the unburned air-fuel mixture explodes violently. This is the most severe and engine-damaging type of abnormal combustion.



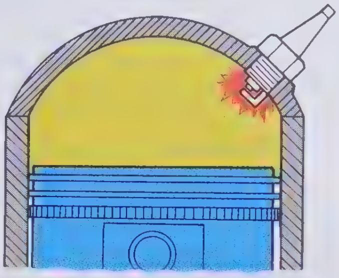
A **Lean mixture**



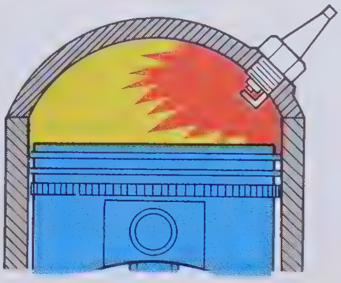
B **Rich mixture**

Figure 20-8. A—Lean fuel mixture has less fuel mixed with the air. B—Rich fuel mixture has more fuel mixed into the air.

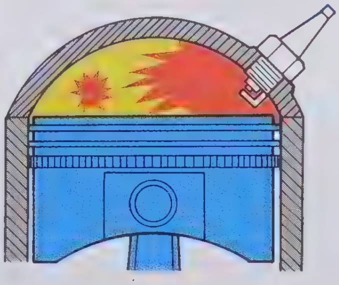
Engine knock is a symptom of detonation. The combustion chamber pressure rises so quickly that parts of the engine vibrate. Detonation sounds like a hammer hitting the side of the engine. **Figure 20-9** shows what happens during detonation. Study the four phases.



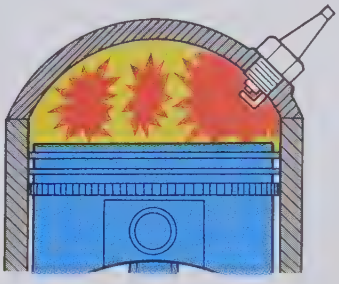
Spark occurs, combustion is slow but normal.



Normal combustion spreads very slowly.



End gas auto-ignites and two flame fronts spread rapidly.



Flames collide with pressure "spike" and knock.

Figure 20-9. Detonation is caused by combustion being too slow. End gas, or unburned air-fuel mixture, ignites and two flame fronts collide with a loud knock.

As you can see, the ***end gas*** (unburned portion of mixture) is heated and pressurized for an extended period. Combustion is too slow because of an incorrect air-fuel mixture, a lack of turbulence, or a fuel distribution problem. This causes the end gas to explode with a "bang" (knock).

Detonation can greatly increase the pressure and heat in the engine combustion chamber. ***Detonation damage*** includes cracked cylinder heads, blown head gaskets, burned pistons, and shattered spark plugs. See **Figures 20-10** and **20-11.**

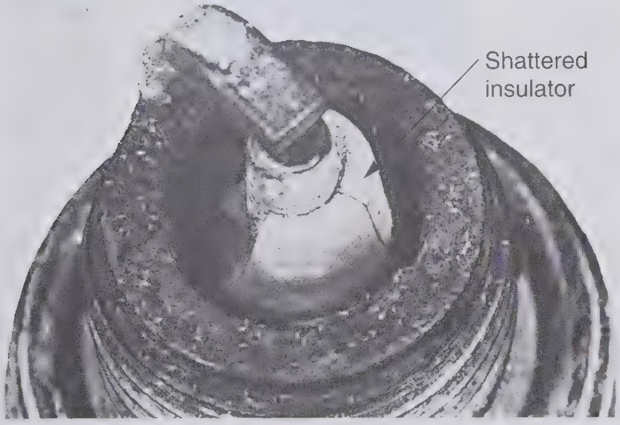


Figure 20-10. Detonation can shatter the insulator on a spark plug. (Champion Spark Plugs)

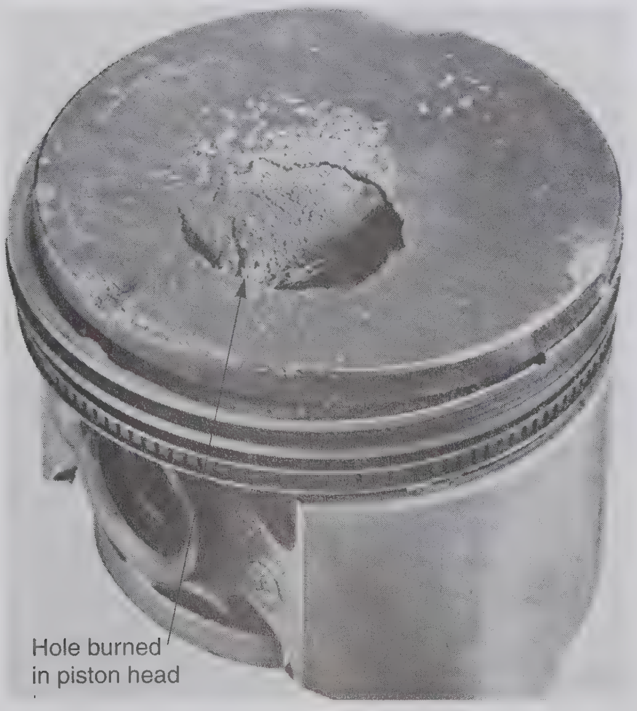

Figure 20-11. Detonation can blow a hole in the piston head. (Champion Spark Plugs)

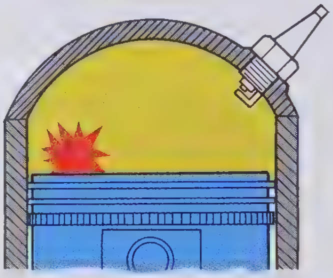
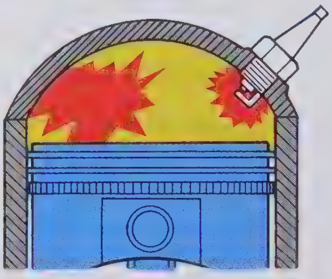
Preignition

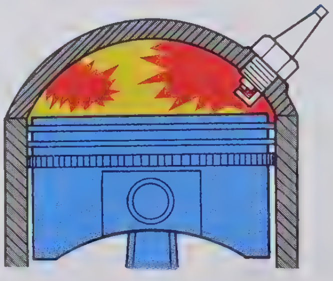
Preignition, or ***surface ignition,*** results when an overheated surface in the combustion chamber ignites the air-fuel mixture. A "hot spot" (overheated bit of carbon, sharp metal edge, hot exhaust valve) causes the mixture to burn prematurely.



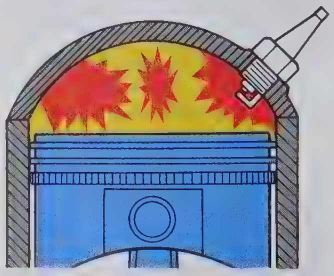
Hot carbon deposit ignites fuel mixture.



Spark plug "fires" and two flame fronts form.



Both flame fronts shoot toward each other at high speed.



Two flames collide causing pressure "spike" and a knock.

Figure 20-12. Preignition is caused by early ignition of the fuel mixture. Abnormal and normal flames collide, producing a pinging noise.

A ***ping,*** or a mild knock, is a light tapping noise that can be heard during preignition. It is not as loud or as harmful as a detonation knock. Study **Figure 20-12.**

Preignition is similar to detonation, but the actions are reversed. Detonation begins *after* the start of normal combustion. Preignition begins *before* the start of normal combustion.

Caution!
Prolonged preignition can produce harmful detonation. If an engine pings or knocks excessively, serious engine damage can result. Correct the problem right away.

Dieseling

Dieseling, also called ***after-running*** or ***run-on***, is a problem in which the engine keeps running after the key is turned off. A knocking, coughing, or fluttering noise is heard as the fuel ignites and the crankshaft spins uncontrollably. When dieseling, the gasoline engine ignites the fuel from heat and pressure, somewhat like a diesel engine. With the ignition key off, the engine runs without voltage to the spark plugs.

The most common causes of dieseling are a high idle speed, carbon deposits in the combustion chambers, low-octane fuel, an overheated engine, or spark plugs that have too high a heat range. This problem will be discussed later in the text.

Spark Knock

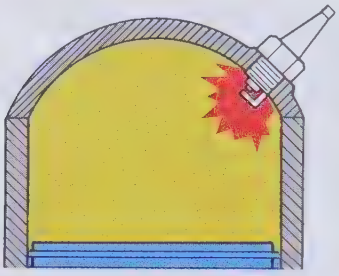
Spark knock is an engine combustion problem caused by the spark plug firing too soon in relation to the position of the piston. Spark timing that is advanced too far causes combustion pressure to slam into the upward-moving piston. This causes maximum cylinder pressure before TDC, not just after TDC as it should.

Figure 20-13 shows what happens during spark knock. Spark knock can also lead to preignition and more damaging detonation.

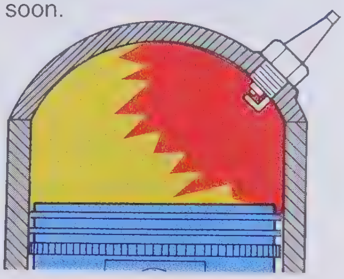
Spark knock and preignition produce about the same symptoms—pinging under load. To find the cause of pinging, first check the ignition timing. If timing is correct, check other possible causes.

Diesel Fuel

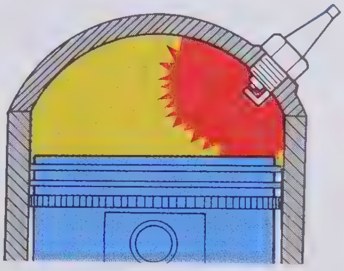
Diesel fuel is the second most popular type of automotive fuel. A gallon of diesel fuel contains more heat energy than a gallon of gasoline. It is a thicker fraction (part) of crude oil. Diesel fuel can produce more cylinder pressure and vehicle movement than an equal amount of gasoline. Diesel fuel now costs about the same as gasoline.



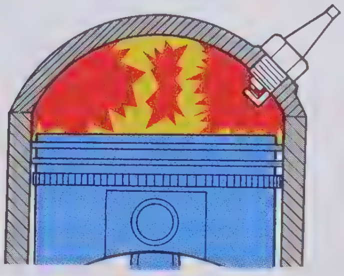
Spark plug "fires" too soon.



Piston moves toward flame front.



Pressure builds as piston slams into combustion flame.



Spark knock occurs because of excessive pressure in cylinder.

Figure 20-13. Spark knock is a ping or knock caused by an ignition timing problem.

Since diesel fuel is thicker and has different burning characteristics than gasoline, a high-pressure injection system must be used to spray the fuel directly into the combustion chambers. A low-pressure injection system or carburetor would not meter the thick diesel fuel properly. Look at **Figure 20-14.**

Diesel fuel will not ***vaporize*** (change from a liquid to a gas) as easily as gasoline. If diesel fuel were to enter the

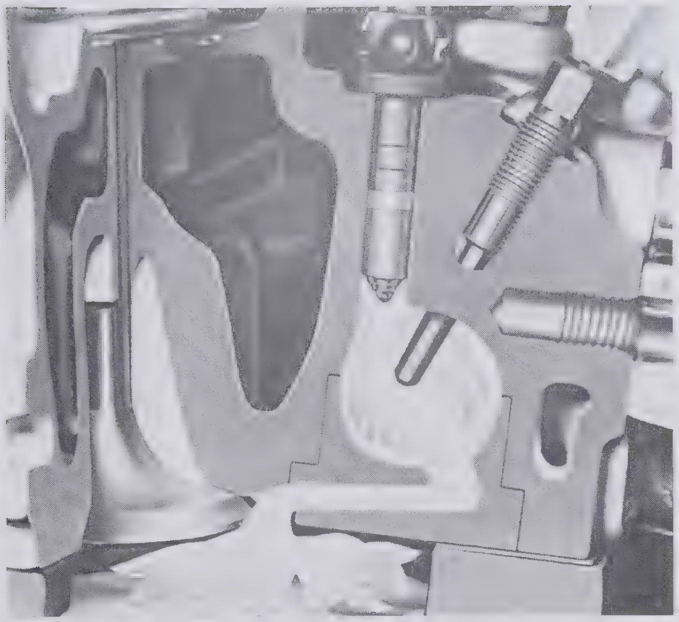


Figure 20-14. A diesel engine is a compression-ignition engine. High pressure heats air in the cylinder. When fuel is sprayed into the hot air, combustion begins.

intake manifold of an engine, it would collect on the inner walls of the manifold. This would upset engine operation.

Combustion requires fuel to be in a vapor state. Diesel engines inject the diesel fuel directly into the combustion chamber. The compressed, hot air vaporizes and burns the fuel.

Diesel Fuel Grades

Diesel fuel grades ensure that diesel fuel sold all over the country has uniform standards. Diesel engine makers are then able to select a diesel fuel grade that meets the needs of their engines. There are three diesel fuel grades: No. 1 diesel, No. 2 diesel, and No. 4 diesel.

No. 2 diesel is normally recommended for use in diesel automotive engines. It is also the only grade of fuel available at many service stations. No. 2 diesel has a medium ***viscosity*** (thickness or weight), which provides proper operating traits for the widest range of conditions.

No. 1 diesel is thinner than No. 2 diesel and is sometimes recommended as a winter fuel. Low temperatures tend to thicken diesel fuel, causing performance problems (hard starting, poor fuel delivery).

Some auto manufacturers allow the use of only No. 2 diesel fuel, with special cold weather additives being used in the winter. In some engines, the thin No. 1 diesel fuel will not provide adequate lubrication. Metal-to-metal contact may occur, causing serious engine damage. When in doubt, refer to the vehicle's service manual.

Caution!
Diesel fuel should not be confused with fuel oil or home heating oil. Diesel fuel contains fewer impurities than fuel oil. Fuel oil should *never* be used in a diesel engine or damage will result.

Diesel Fuel Cloud Point

One of the substances in diesel fuel is ***paraffin*** (wax). At very cold temperatures, this wax can separate from the other parts of the diesel fuel. When this happens, the fuel will turn cloudy or milky. ***Cloud point*** is the temperature at which paraffin separates out of the fuel. At cloud point, the paraffin can clog the fuel filters and prevent diesel engine operation.

Diesel Fuel Water Contamination

Water contamination is a common problem with diesel engines. When mixed with diesel fuel, water can clog filters and corrode components. The parts in diesel injection pumps and nozzles are very precise. They can be easily damaged by water.

Many late-model diesel injection systems have ***water separators*** to prevent water damage. These will be covered in later chapters.

Diesel Fuel Cetane Rating

A ***cetane rating*** indicates the cold starting ability of diesel fuel. The higher the cetane number, the easier the engine will start and run in cold weather. Most automakers recommend a cetane rating of about 45. This is the average cetane value of No. 2 diesel fuel.

A cetane number, in some ways, is the opposite of a gasoline octane number. This is shown in **Figure 20-15.** A high cetane number means the fuel will ignite easily from heat and pressure. In a diesel, the fuel must ignite and burn as soon as it touches the hot air in the combustion chamber.

Diesel Combustion

A diesel engine is a ***compression-ignition engine.*** This engine compresses air until it is hot enough to ignite the fuel. A spark plug would not ignite diesel fuel properly. If gasoline were used in a diesel engine, it would detonate on the compression stroke and not produce useful energy.

Diesel fuel is thick and hard to ignite. A high-pressure mechanical pump and nozzle force the fuel into the engine combustion chamber. An extremely high compression ratio heats the air in the cylinder. When fuel is sprayed

Slow burning

Figure 20-15. Diesel fuel cetane rating is the opposite of gasoline octane rating.

into the hot air, it begins to burn. **Figure 20-16** shows the phases of normal diesel combustion:

A— The piston moves up to compress and heat the air in the cylinder. Note that this is different than a gasoline engine, which compresses both fuel and air.

B— Diesel fuel is injected directly into the combustion chamber. The hot air makes the fuel begin to burn and expand.

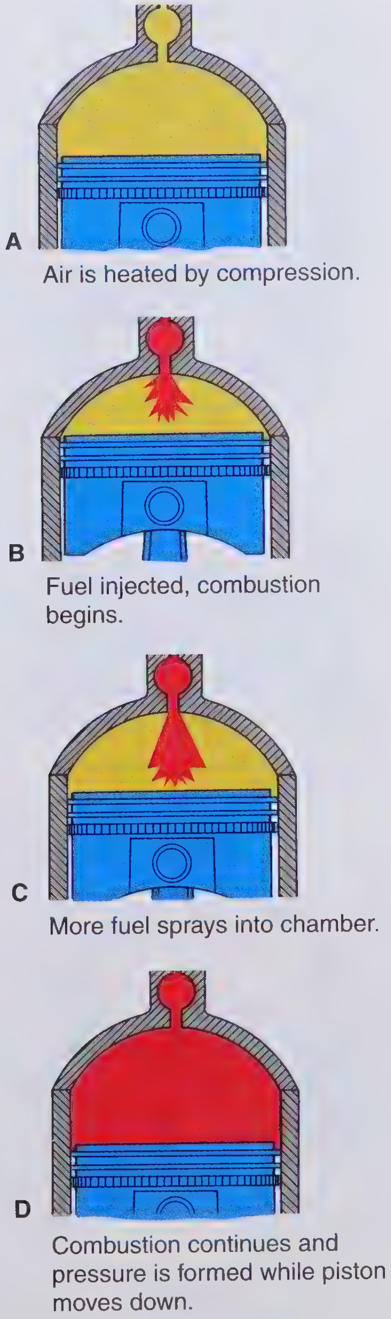
C— More fuel is sprayed into the chamber. More pressure is developed and the piston begins to move down in the cylinder.

D— The rest of the fuel is injected into the chamber. Pressure continues to form, pushing the piston down on the power stroke.

Note that fuel is injected into the engine for several degrees of crankshaft rotation. This causes a smooth, steady buildup of pressure for quiet diesel engine operation.

Diesel Combustion Knock

When compared to gasoline engines, diesel engines knock almost all the time. The engine clatters and rattles as the diesel fuel ignites in the combustion chambers.



A
Air is heated by compression.
B
Fuel injected, combustion begins.
C
More fuel sprays into chamber.
D
Combustion continues and pressure is formed while piston moves down.

Figure 20-16. Normal diesel combustion.

Diesel knock occurs when too much fuel ignites at one time, producing a loud knocking noise. Excessive diesel knock can reduce engine power, fuel economy, and engine life.

Ignition lag is the time it takes diesel fuel to heat up, vaporize, and begin to burn. It is the time lapse between initial fuel injection and actual ignition (burning).

Ignition lag is a major controlling factor of diesel knock. If lag time is too long, a large amount of fuel can ignite, producing a louder-than-normal knock. A high cetane fuel, which has a short lag time, reduces the chances of diesel knock. **Figure 20-17** shows the basic phases of diesel knock. Study this illustration.

Diesel knock can be due to a cold engine, a low-cetane fuel, an improper fuel spray pattern, or incorrect injection timing. These will be discussed in later chapters.

Alternative Fuels

Alternative fuels include any fuel other than gasoline and diesel fuel. Liquefied petroleum gas, alcohol, and hydrogen are examples of alternative fuels.

Liquefied Petroleum Gas

Liquefied petroleum gas (LPG) is sometimes used as a fuel for automobiles and trucks. It is one of the lightest fractions of crude oil. Chemically, LPG is similar to gasoline. However, at room temperature and pressure, LPG is a vapor, *not* a liquid. Refer again to **Figure 20-3.**

A special fuel system is needed to meter the gaseous LPG into the engine. One is shown in **Figure 20-18.** Note the names and construction of the basic parts.

LPG is commonly used in industrial equipment, such as fork lifts. It is also used in some fleet vehicles that always refuel at the same location. Being a gas, LPG burns cleanly, producing few exhaust emissions.

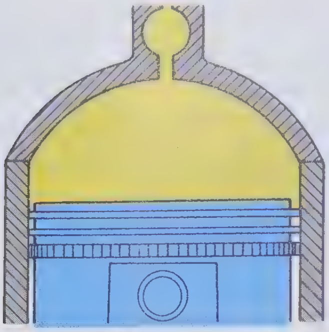
Alcohol

Alcohol has the potential to be an excellent alternative fuel for automotive engines. The two types of alcohol used in automobiles are ethyl alcohol and methyl alcohol.

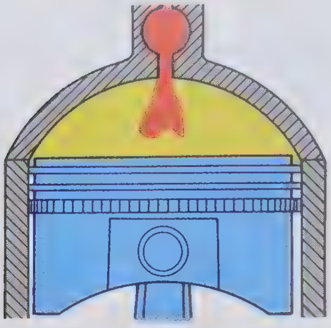
Ethyl alcohol, also called ***grain alcohol*** or ***ethanol***, is made from farm crops. Grain, wheat, sugarcane, potatoes, fruit, oats, soy beans, and other crops rich in carbohydrates can be made into ethyl alcohol. This type alcohol is a colorless, harsh tasting, toxic, and highly flammable liquid.

Methyl alcohol, also termed ***"wood alcohol"*** or ***methanol***, can be made out of wood chips, petroleum, garbage, and animal manure. It has a strong odor, is colorless, poisonous, and very flammable.

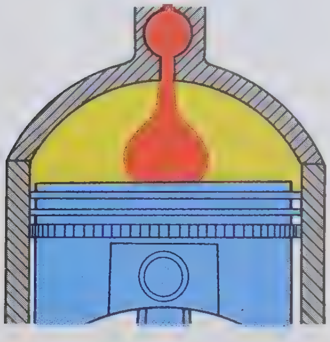
Alcohol is a clean-burning fuel for automobiles. It is not commonly used because it is expensive to use and produce. Also, the vehicle's fuel system requires modification before it can burn straight alcohol. Almost twice as much alcohol must be burned, compared to gasoline. This reduces fuel economy by 50%.



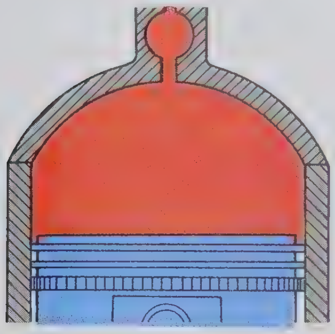
Air is compressed and heated.



Fuel is injected but fails to vaporize and burn.



More fuel injected, but still no combustion.



All of the fuel suddenly ignites with a "bang."

Figure 20-17. Diesel knock is caused by too much fuel igniting at one time. The fuel does not ignite quick enough when injection begins.

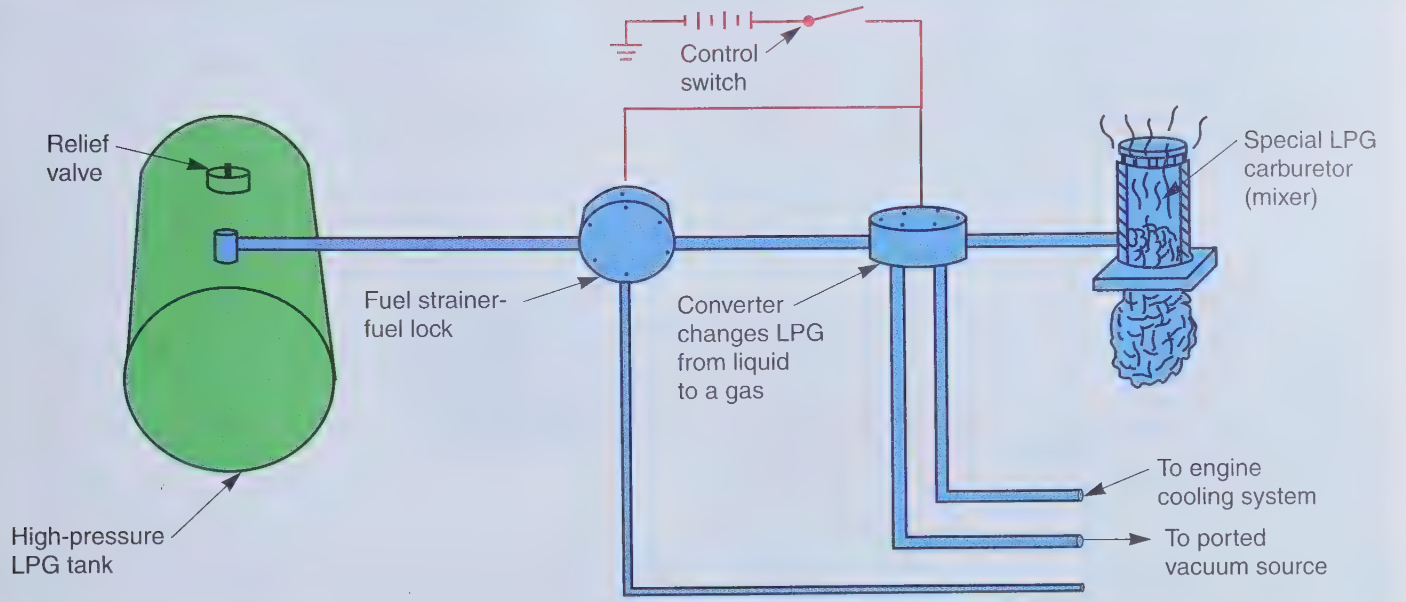


Figure 20-18. An LPG fuel system uses a high-pressure storage tank. A fuel strainer-fuel lock cleans fuel and prevents leakage when the engine is not running. A converter uses heat from the engine coolant to change the liquid LPG into a gas. A special carburetor meters LPG into the engine.

Tech Tip!
Methanol is commonly used as a racing fuel. It burns very hot but does not produce a visible flame. This can be very dangerous because you cannot see the flames if there is a fire. For increased safety, racing organizations have required the use of additives in methanol racing fuel to make its flame visible.

Gasohol

Gasohol, as the name implies, is a mixture of gasoline (usually 87 octane gasoline) and alcohol (usually grain alcohol). The mixture can range from 2–20% alcohol. In most cases, gasohol is a blend of 10% alcohol and 90% gasoline. See **Figure 20-19.**

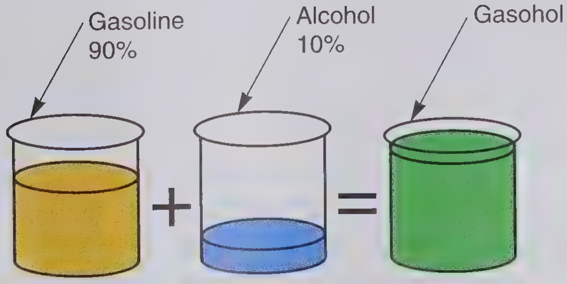

Figure 20-19. Gasohol is usually a mixture of 10% alcohol and 90% gasoline. (Ethyl Corp.)

Gasohol is commonly used as an alternative fuel in motor vehicles because fuel system and engine modifications are not needed. Many gas stations sell gasohol as a high-octane fuel. The alcohol tends to reduce the knocking tendencies of the gasoline. It acts like an antiknock additive.

For example, 10% alcohol can increase 87 octane gasoline to 91 octane. Gasohol can be burned in a high-compression, high-horsepower engine without detonating and knocking.

Synthetic Fuels

Synthetic fuels are fuels made from coal, shale oil rock (rock filled with petroleum), and tar sand (sand filled with petroleum). See **Figure 20-20.**

Synthetic fuels are synthesized (changed) from a solid hydrocarbon state to a liquid or gaseous state. Synthetic fuels are being experimented with as a means of supplementing crude oil. As crude oil-based fuels become more expensive, synthetic fuels will become more practical.

Hydrogen

Hydrogen is a highly flammable gas that is a promising alternative fuel of the future. Hydrogen is one of the most abundant elements on our planet. It can be produced through the electrolysis of water (sending

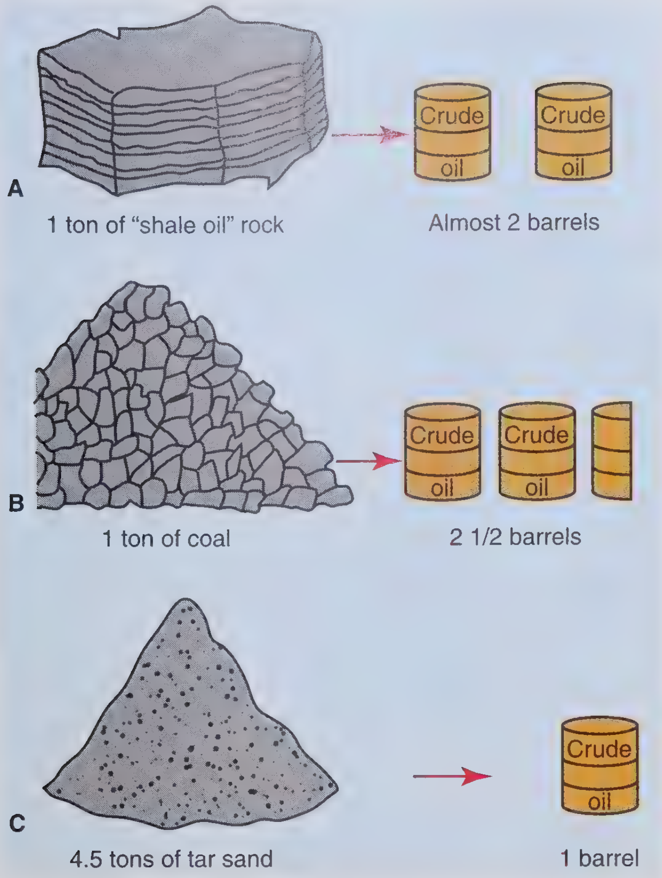

Figure 20-20. Synthetic sources of oil. A—Shale rock can be converted into oil. B—Coal can produce about two and one-half barrels of oil per ton. C—Four and one-half tons of tar can be changed into about one barrel of oil.

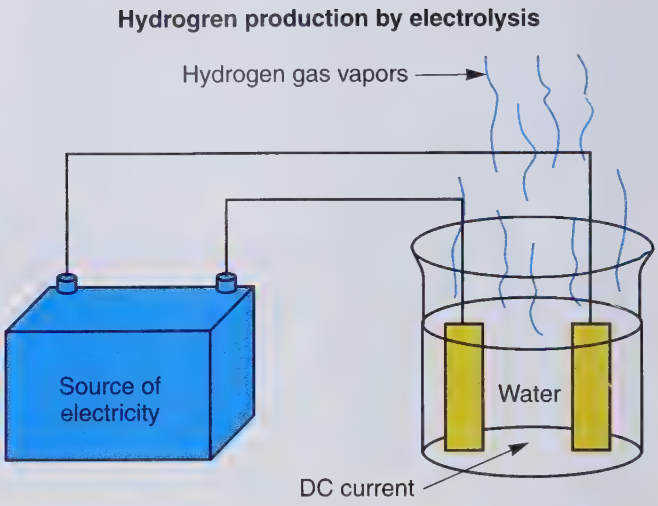

Figure 20-21. Hydrogen gas can be made through the electrolysis of water. Solar cells, wind energy, or ocean thermal energy may make production feasible some day.

electric current through saltwater). This is illustrated in **Figure 20-21.**

Hydrogen is an ideal fuel. Hydrogen burns almost perfectly, leaving only water and harmless carbon dioxide as by-products.

Many manufacturers are now working to develop hydrogen-powered vehicles. Presently, hydrogen is expensive to make and store. However, as we use up our supply of crude oil, we may someday make hydrogen a major source of automotive fuel.

Duff's Garage

Problem: Mrs. Shy drives her 2002 Cadillac Deville into the shop for service. She says the car seems to be running fine, but it is making a noise that sounds like there is a woodpecker under the hood.

Diagnosis: Duff drives the vehicle to verify the problem. He notices a light, erratic pinging sound coming from the engine compartment during acceleration. Duff suspects the sound is the result of using low-octane fuel in a high-compression engine.

Duff questions Mrs. Shy about the type of gasoline she uses in the vehicle. She informs him that she uses regular gasoline because it is cheaper than the premium grades. She adds that she spent so much for the car that she has been trying to save a little money on gasoline. Duff checks the owner's manual, which specifies that fuel with an octane rating of 91 or higher should be used in the vehicle.

Repair: Duff assigns the repair to one of his apprentice technicians. He instructs the technician to drain the fuel tank and then refill it with "premium" gasoline. The apprentice does as he is instructed. He then starts the car and allows it to run for a few minutes before performing a test drive. During the test drive, no pinging or knocking sounds are heard. When the apprentice returns the car to Mrs. Shy, he shows her the fuel octane rating information in the owner's manual and explains the importance of using the correct grade of gasoline.

Summary

- Petroleum, also called crude oil, is oil taken directly out of the ground.
- Gasoline is the most common type of automotive fuel.

- The octane rating of gasoline is a measurement of the fuel's ability to resist knocking or pinging.
- Normal gasoline combustion occurs when the spark plug ignites the fuel and burning progresses smoothly through the air-fuel mixture.
- A stoichiometric fuel mixture is a chemically correct, or perfect, air-fuel mixture.
- Detonation results when part of the unburned air-fuel mixture explodes violently.
- Preignition results when an overheated surface in the combustion chamber ignites the fuel mixture.
- Dieseling, also called after-running or run-on, occurs when the engine keeps running after the key is turned off.
- Diesel fuel is the second most popular type of automotive fuel.
- No. 2 diesel fuel is normally recommended for use in automotive diesel engines.
- A cetane rating indicates the cold starting ability of diesel fuel.
- Alternative fuels include any fuel other than gasoline and diesel fuel. LPG, alcohol, and hydrogen are examples of alternative fuels.

Review Questions—Chapter 20

Please do not write in this text. Place your answers on a separate sheet of paper.

1. _____ _____, also called _____, is oil taken directly out of the ground.
2. What are hydrocarbons?
3. Crude oil is converted into more useful substances at a(n) _____.
4. _____ are extra chemicals added to gasoline to improve its operating characteristics.
5. The _____ of gasoline is a measurement of the fuel's ability to resist knock or ping.
6. If an automaker recommends gasoline with an octane number of 91, 87 octane gasoline is also acceptable. True or False?
7. Which of the following is *not* needed for proper combustion?
   (A) Air.
   (B) Compression.
   (C) Condensation.
   (D) Ignition.
8. Describe normal gasoline combustion.
9. Define the term "stoichiometric fuel mixture."
10. A(n) _____ air-fuel mixture ratio contains a large amount of air.
11. A(n) _____ air-fuel mixture ratio contains a large amount of fuel.
12. What are the results of lean and rich air-fuel mixtures?
13. Explain detonation, preignition, spark knock, and dieseling in a gasoline engine.
14. How does diesel fuel differ from gasoline?
15. Explain how ignition lag affects diesel combustion.
16. _____ is made from farm crops and _____ can be made out of wood chips, petroleum, garbage, and animal manure.
17. What is gasohol?

18. Gasohol can normally be used without major engine or fuel system modifications. True or False?
19. A certain gasohol mixture contains 5% alcohol. What is the approximate percentage of gasoline in this mixture?
    (A) 85%.
    (B) 92%.
    (C) 90%.
    (D) 95%.
20. Which of the following does *not* pertain to hydrogen as an alternative fuel?
    (A) Made from most abundant element.
    (B) Produced through electrolysis.
    (C) Burns without toxic emissions.
    (D) Economical or inexpensive to make.

ASE-Type Questions

1. Crude oil is used to make each of these *except:*
    (A) LPG.
    (B) gasoline.
    (C) hydrocarbons.
    (D) hydrogen.
2. Crude oil is a mixture of:
    (A) liquids.
    (B) semisolids.
    (C) hydrocarbons.
    (D) All of the above.
3. Which of these is a commonly used antiknock additive?
    (A) Naphthas.
    (B) Oxygenates.
    (C) Petrochemicals.
    (D) None of the above.
4. Which of the following is the measurement of a fuel's ability to resist knock?
    (A) Octane rating.
    (B) Cetane rating.
    (C) Clouding point.
    (D) All of the above.
5. Normal combustion takes about:
    (A) 1/100 of a second.
    (B) 3/1000 of a second.
    (C) 3/10,000 of a second.
    (D) 1/50,000 of a second.
6. A chemically correct air-fuel ratio is called a:
    (A) rich air-fuel mixture.
    (B) lean air-fuel mixture.
    (C) combustible fuel mixture.
    (D) stoichiometric fuel mixture.
7. Each of these is a form or result of abnormal combustion *except:*
    (A) detonation.
    (B) ignition lag.
    [✓ *(C) engine knock.*]
    (D) after-running.
8. A diesel fuel substance that can separate from other fuel parts and clog fuel filters is:
    (A) lead.
    (B) water.
    (C) carbon.
    [✓ *(D) paraffin.*]
9. Automakers recommend a cetane rating of about:
    (A) 45.
    (B) 50.
    (C) 55.
    (D) 60.
10. When looking at cetane ratings, Technician A says that the higher a cetane number is, the easier an engine starts and runs in cold weather. Technician B says that the higher a cetane number is, the easier a fuel ignites from heat and pressure. Who is right?
    (A) A only.
    (B) B only.
    [✓ *(C) Both A and B.*]
    (D) Neither A nor B.

Activities—Chapter 20

1. Obtain literature about automotive fuels and prepare a written report on additives and their properties.
2. Research magazines and newspapers for information about the manufacture of alcohol for use as an automotive fuel.
3. Research and discuss modifications of engines for use of LPG as a fuel.

21 Fuel Tanks, Pumps, Lines, and Filters

After studying this chapter, you will be able to:

- Define the major parts of a fuel supply system.
- Describe the operation of mechanical and electric fuel pumps.
- Describe the construction and action of air filters.
- Explain the tests used to diagnose problems with fuel pumps, fuel filters, and fuel lines.
- Repair a fuel line or replace a fuel hose.
- Locate and replace fuel filters in both gasoline and diesel fuel systems.
- State safety rules for working on fuel supply systems.
- Correctly answer ASE certification test questions on fuel tanks, fuel pumps, fuel lines, fuel filters, and air filters.

A ***fuel system*** provides a combustible air-fuel mixture to power the engine. Introduced in Chapter 1, there are several types of fuel systems. Today's cars commonly use gasoline injection systems or diesel injection systems. Older vehicles use carburetors.

A modern fuel system has three subsystems:

- ***Fuel supply system***—provides filtered fuel to the gasoline injectors, the diesel injection pump, or the carburetor.
- ***Air supply system***—provides clean combustion air to the engine.
- ***Fuel metering system***—controls the amount of fuel that enters the engine.

This chapter explains the construction, operation, and service of fuel tanks, fuel lines, fuel filters, air filters, and fuel pumps. These parts make up the fuel and air supply systems. The information in this chapter will prepare you for later chapters on fuel metering systems. Study carefully!

Fuel Supply System

A fuel supply system draws fuel from the fuel tank and forces it into the fuel metering device (gasoline injectors, diesel injection pump, or carburetor), **Figure 21-1.** Modern vehicles use electric fuel pumps. Older engines use mechanical (engine-driven) fuel pumps. Some older vehicles use both types: an electric pump on the fuel tank and a mechanical pump on the engine.

The basic parts of a fuel supply system include:

- ***Fuel tank***—stores gasoline, diesel fuel, gasohol, alchohol, LPG, or other combustible material.
- ***Fuel lines***—carry fuel between the tank, pump, and other parts of the system.
- ***Fuel pump***—draws fuel from the tank and forces it to the engine or fuel-metering device.
- ***Fuel filters***—remove contaminants in the fuel.

Fuel Tanks

An automotive ***fuel tank*** must safely hold an adequate supply of fuel for prolonged engine operation. With front-engine vehicles it is mounted in the rear of the car, under the trunk or the rear seat. See **Figure 21-1.**

The size of a fuel tank determines, in part, a car's ***driving range*** (distance a vehicle can be driven without stopping for fuel). ***Fuel tank capacity*** is the volume of fuel (in gallons or liters) a fuel tank can hold. Average fuel tank capacity is 12–25 gallons (45–95 liters).

Fuel Tank Construction

Fuel tanks are usually made of thin sheet metal or plastic. The main body of a metal tank is made by soldering or welding two formed pieces of sheet metal together. As shown in **Figure 21-2,** other parts (filler neck, baffles, vent tubes, expansion chamber) are added to form the complete fuel tank assembly. A zinc alloy is normally plated to the sheet metal to keep the tank from rusting.

Figure 21-2. Basic parts of a fuel tank assembly. (DaimlerChrysler)

The ***fuel tank filler neck*** is the extension tube that allows the gas pump nozzle to be used to fill the tank with fuel. The ***filler cap*** fits on the end of the filler neck, **Figure 21-2.** The neck extends from the tank through the body of the car. A flexible hose is normally used as part of the filler neck. It allows tank vibration without part breakage.

A ***spillback ball*** is a large "ping pong–type" ball in the fuel tank filler neck to prevent fuel from leaking out of the vehicle during fillups.

Modern ***filler caps*** are sealed to prevent the escape of fuel and fuel vapors (emissions) from the tank. Normally, they are *not* vented to the atmosphere.

Fuel tank baffles are placed inside the fuel tank to keep fuel from sloshing, or splashing, around in the tank. The baffles are metal plates that restrict fuel movement when the car accelerates, decelerates, or turns a corner.

Fuel tank straps are used to secure the tank to the vehicle. They are thick steel bands that bolt around the fuel tank to hold it in place, **Figure 21-3.** Some tanks are held in place with bolts that pass through the tank's flanges. A ***fuel tank cover*** is sometimes used to prevent damage from road debris.

Tank Pickup-Sending Unit

A ***tank pickup-sending unit*** extends down into the tank to draw out fuel and operate the fuel gauge. One is shown in **Figure 21-4.** A coarse filter is usually placed on the end of the pickup tube to strain out debris.

in the instrument panel. **Figure 21-5** shows the basic action of a fuel tank sending unit.

When the fuel level in the tank is low (float down), the sending unit has a high resistance. Only a small amount of current flows to the gauge. The gauge shows a low fuel level.

When the tank is full (float up), the sending unit has a low resistance. More current flows to the gauge, and the gauge needle moves to the full position.

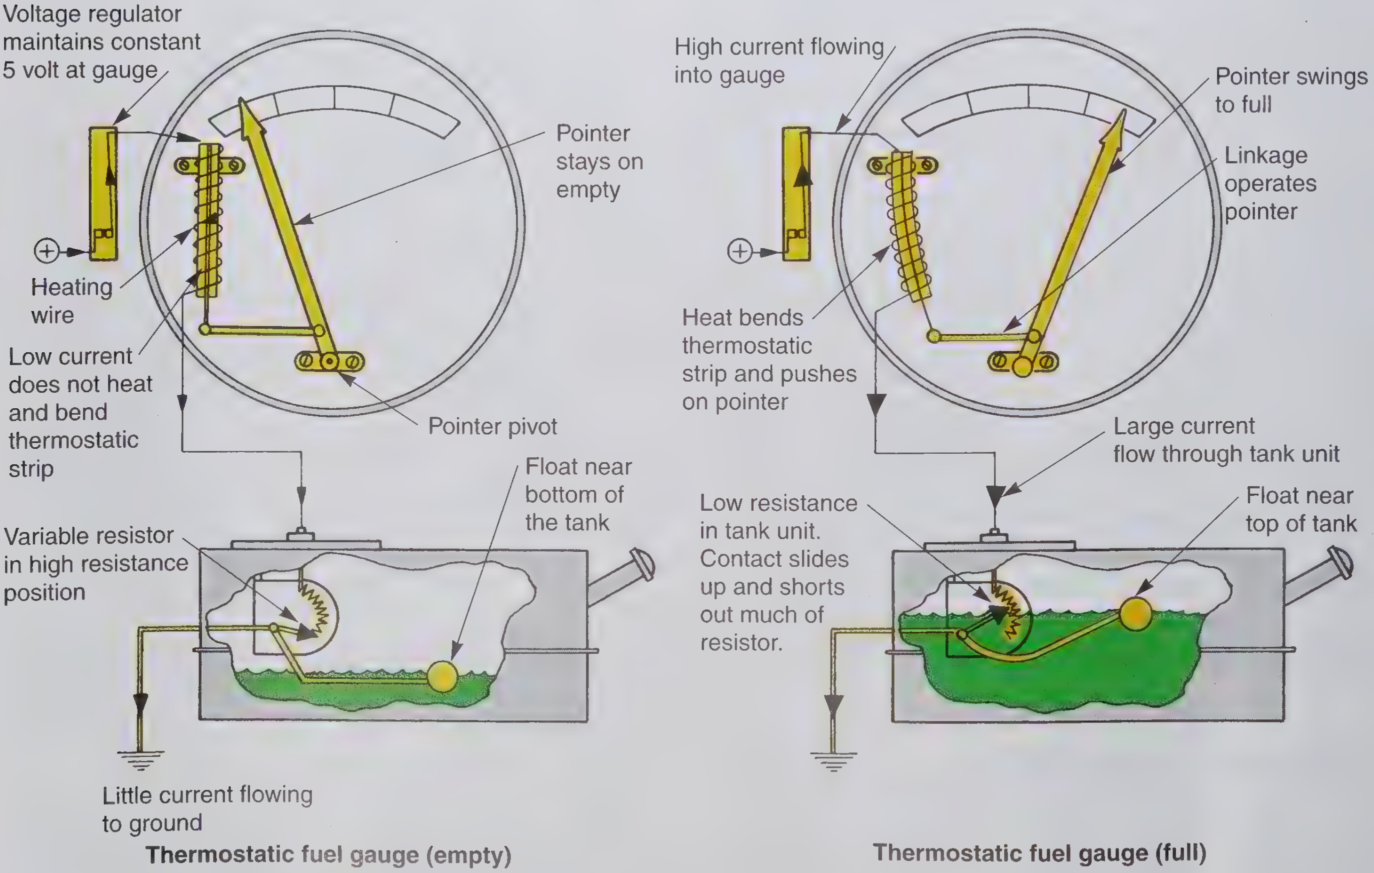
Fuel Tank Pressure Sensor

A ***fuel tank pressure sensor*** is used to monitor the buildup of fuel tank pressure in late-model vehicles equipped with OBD II systems. The sensor aids in the operation of the evaporative emissions control system. This system is detailed in Chapter 43.

Fuel Lines and Hoses

Fuel lines and ***fuel hoses*** carry fuel from the tank to the engine. The main fuel line allows the fuel pump to draw fuel out of the tank. The fuel is pulled through this line to the pump and is then forced into the metering section of the fuel system.

Figure 21-6 shows a complete set of fuel lines, including the fuel vapor lines for the evaporative emissions control system. Study the routing of the lines. Note how they connect to the fuel system components.



Voltage regulator maintains constant 5 volt at gauge

Figure 21-6. Study fuel and emission control lines. Note the location of the fuel pump, filters, and other devices. (Mazda)

Fuel lines are normally made of strong, double-wall steel tubing. For fire safety reasons, a fuel line must be able to withstand the constant and severe vibration produced by the engine and road surface. See **Figure 21-7**.

A ***fuel rail*** is a large-diameter fuel line that feeds fuel into multiport gasoline injectors. Is serves the same purpose as the fuel line but provides a greater volume of fuel right before the injectors. The fuel rail prevents any injector from starving for fuel under high-demand conditions.

Fuel hoses, made of synthetic rubber, are needed where severe movement occurs between parts. For example, a fuel hose is used between the main fuel line and the engine. The engine is mounted on rubber motor mounts. The soft mounts allow the engine some movement in the car frame. A flexible hose can absorb this movement without breaking. ***Hose clamps*** secure fuel hoses to the fuel lines or metal fittings.

Fuel filter

Figure 21-7. Three metal lines often run between the fuel tank and the engine: the main fuel supply line (tank to engine), the fuel return line (engine to tank), and the fuel vapor line (tank to storage canister). (Honda)

Plastic Fuel Lines

Plastic fuel lines, also called fuel pipes, are made of high-strength nylon tubing, which can withstand the chemical action, pressure, and heat encountered in fuel system applications. They can be used instead of metal lines in some installations. Plastic lines are light and flexible.

Fuel feed, fuel return, and injector feed lines can be made of plastic. The inside diameter of the plastic line determines its size when ordering. Rubber hose or heavy corrugated plastic conduit is often placed over the plastic line to protect it from chafing, vibration, and heat.

Quick-disconnect fittings are often used with plastic fuel lines. One end of the fuel line is male, and the other end is female. An O-ring seal is compressed inside the fitting to prevent leaks.

Fuel Return System

Most fuel injected vehicles, as well as some carbureted vehicles, use a ***fuel return system*** to cool the fuel and prevent vapor lock (bubbles form in overheated fuel and stop fuel flow). In these systems, a fuel return line carries excess fuel back to the tank. This keeps cool fuel constantly flowing through the system. See **Figure 21-1.**

Returnless Fuel Injection Systems

Some late-model vehicles are equipped with ***returnless fuel injection systems.*** As their name implies, these systems do not have fuel return lines. Some returnless systems use a pressure regulator mounted on the in-tank electric fuel pump assembly. When system pressure exceeds specifications, the regulator routes fuel back to the tank.

In other returnless systems, the computer adjusts pressure at the injectors by varying the output of the electric fuel pump. Based on signals from a fuel rail–mounted pressure sensor and several other sensors, the computer increases or decreases the current sent to the pump motor.

Figure 21-8. Variations of automotive fuel filters. (Fram, Saab, Ford, DaimlerChrysler)

Fuel Filters

Fuel filters stop contaminants (rust, water, corrosion, sand, dirt) from entering the fuel lines, hoses, throttle body, injectors, pressure regulator, injection pump, strainer and any other part that could be damaged by foreign matter. A fuel filter is normally located on the fuel tank pickup tube. A second fuel filter (main fuel filter) is commonly located in the main fuel line. **Figure 21-8** shows various types of fuel filters.

Fuel Filter Construction

Most fuel filters use ***pleated paper elements*** to trap contaminants present in the fuel. Others use a ***sintered bronze*** (porous metal) element. Both types are capable of stopping very small particles. Some filters are also capable of trapping water.

A ***bowl fuel filter*** can be found on older gasoline and diesel engines. Some use a glass bowl that allows the technician to see the filter element. When the element becomes dirty, the technician can remove the bowl for service.

A ***canister fuel filter*** is housed inside a metal container. When the filter requires replacement, a new element can be installed inside the container.

Fuel Pumps

A ***fuel pump*** draws fuel out of the tank and forces it to the engine under pressure. There are two basic types of fuel pumps: mechanical and electric. Electric pumps are used on today's vehicles.

Mechanical Fuel Pumps

A ***mechanical fuel pump*** is usually powered by an ***eccentric*** (egg-shaped lobe) on the engine camshaft. This type of fuel pump bolts to the side of the engine block. A gasket prevents oil leakage between the pump and engine block. See **Figure 21-9.**

Mechanical fuel pumps can still be found in carburetor-type fuel systems. Since the mechanical pump uses a back-and-forth motion, it is a ***reciprocating*** pump.

Mechanical Fuel Pump Construction

The ***rocker arm,*** also called the actuating lever, is a metal arm that pivots in the middle, **Figure 21-9.** The outer end of the rocker arm rides on the camshaft eccentric. The inner end operates the diaphragm.

The fuel pump ***return spring*** keeps the rocker arm pressed against the eccentric. Without a return spring, the rocker arm would make a loud clattering sound as the eccentric lobe hit the rocker arm.

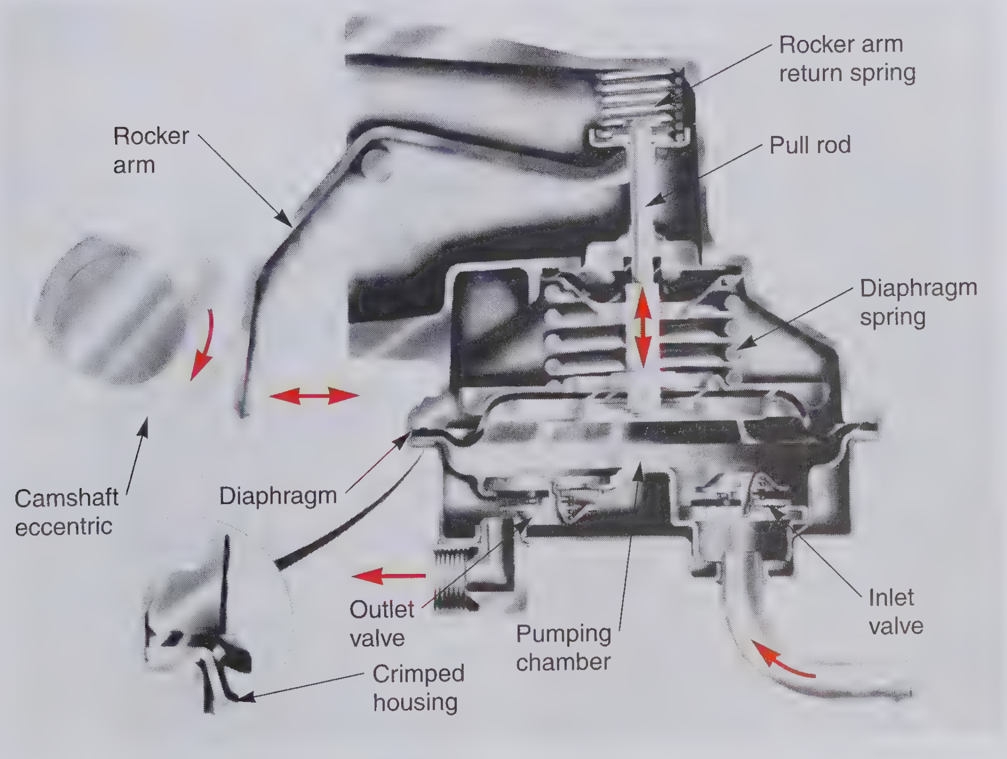

Figure 21-9. Cutaway view of a mechanical fuel pump. Note part names and locations. (AC-Delco)

The *diaphragm* is a synthetic rubber disc clamped between the halves of the pump body. A metal pull rod is mounted on the diaphragm to connect the diaphragm with the rocker arm. The ***diaphragm spring,*** when compressed, pushes on the diaphragm to produce fuel pressure and flow.

Two ***check valves*** are used in a mechanical fuel pump: the inlet check valve and the outlet check valve. Fuel flows easily through the valves in one direction but cannot flow through in the other direction. The two check valves are reversed. This causes the fuel to enter through one valve and exit through the other.

Mechanical Fuel Pump Operation

During the ***intake stroke,*** the eccentric lobe pushes on the rocker arm. This pulls the diaphragm down and compresses the diaphragm spring. The area in the pumping chamber increases, and the resulting vacuum pulls fuel through the inlet check valve. This fills the pump with fuel. See **Figure 21-10A.**

On the ***output stroke,*** the eccentric lobe rotates away from the rocker arm. This releases the diaphragm, **Figure 21-10B.** The diaphragm spring then pushes on the diaphragm and pressurizes the fuel in the pumping chamber. The amount of spring tension controls fuel pressure. The fuel flows out through the outlet check valve.

When an engine is running slowly, the fuel pump would produce more fuel than the engine consumes. For this reason, the fuel pump is made to idle when fuel is not needed. See **Figure 21-10C.** The diaphragm pull rod is free to slide through the rocker arm when fuel pressure compresses the pump spring. This lets the rocker arm move up and down while the diaphragm remains stationary. Diaphragm spring tension maintains fuel pressure.

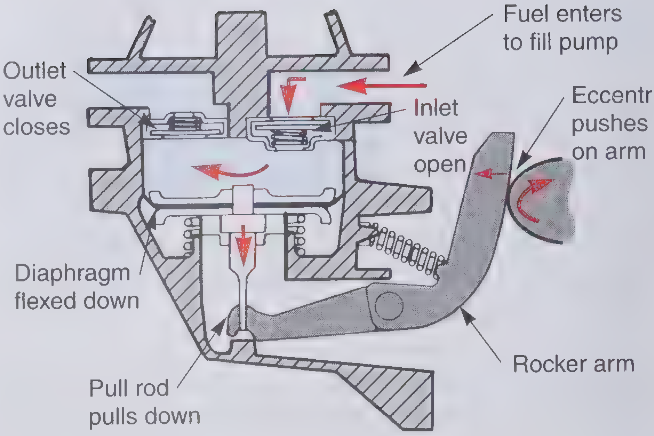
Vapor Lock

Vapor lock is a problem created when bubbles in overheated fuel reduce or stop fuel flow. **Figure 21-11** shows vapor lock in a mechanical fuel pump.

During vapor lock, engine heat transfers through the metal parts of the pump and into the fuel. The fuel "boils," forming bubbles that displace fuel. This can reduce fuel pump output and cause engine performance problems.

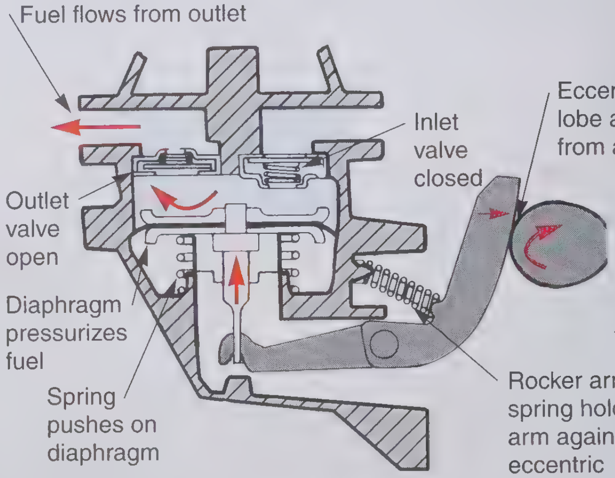
Electric Fuel Pumps

An ***electric fuel pump,*** like a mechanical pump, produces fuel pressure and flow for the fuel metering section of a fuel system. Electric fuel pumps are commonly used on all types of modern engines.



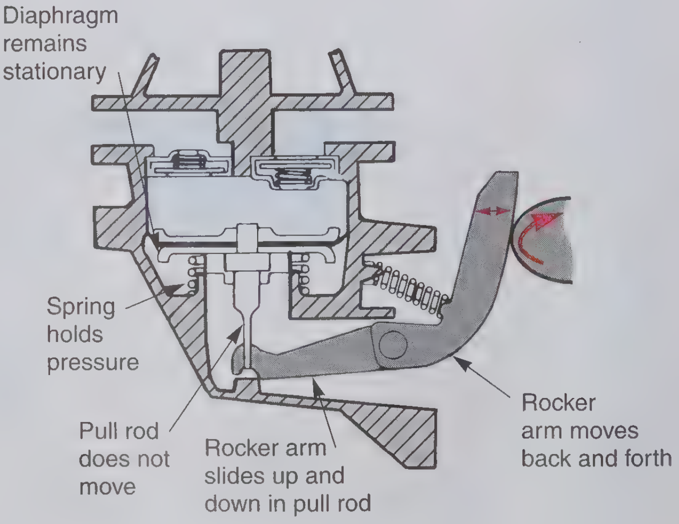
Outlet valve closes
Fuel enters to fill pump
Inlet valve open
Eccentric pushes on arm
Diaphragm flexed down
Rocker arm
Pull rod pulls down

A — Intake stroke



Fuel flows from outlet
Inlet valve closed
Eccentric lobe away from arm
Outlet valve open
Diaphragm pressurizes fuel
Spring pushes on diaphragm
Rocker arm spring holds arm against eccentric

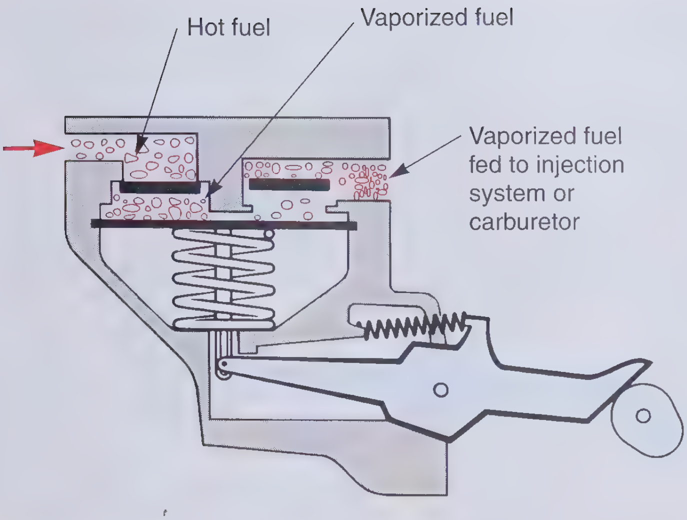
B — Output stroke



Diaphragm remains stationary
Spring holds pressure
Pull rod does not move
Rocker arm slides up and down in pull rod
Rocker arm moves back and forth

C — Idling

Figure 21-10. Mechanical fuel pump operation.



Hot fuel
Vaporized fuel
Vaporized fuel fed to injection system or carburetor

Figure 21-11. Vapor lock is caused when too much engine heat is transferred into the fuel. Bubbles form and displace fuel. This can prevent fuel from flowing through system. (Ford)

An electric fuel pump can be located inside the fuel tank or in the fuel line between the tank and the engine. A few vehicles have one pump in the fuel tank and a second pump in the fuel line. In many late-model vehicles, the tank sending unit is an integral part of the in-tank fuel pump assembly. See **Figure 21-12.**

An electric fuel pump has advantages over a mechanical fuel pump. An electric pump can produce almost instant fuel pressure. A mechanical pump slowly builds pressure as the engine is cranked for starting. Also, most electric fuel pumps are rotary-type pumps. They produce a smoother flow of fuel (fewer pressure pulsations) than reciprocating, mechanical pumps.

Since most electric fuel pumps are located away from the engine, vapor lock is less likely. An electric fuel pump pressurizes all the fuel lines that are near engine heat. This also helps prevent vapor lock because the pressure makes it more difficult for bubbles to form.

Rotary Fuel Pumps

Rotary fuel pumps include the impeller type, the roller vane type, and the sliding vane type. They all use a circular, or spinning, motion to produce pressure.

An ***impeller electric fuel pump*** is a centrifugal pump. Normally, it is located inside the fuel tank. See **Figure 21-13.** This pump uses a small dc motor to spin the impeller (fan blade). The impeller blades cause the fuel to move outward due to centrifugal force (spinning matter is propelled outward). This produces enough pressure to move the fuel through the fuel lines. **Figure 21-14** shows an in-tank impeller pump and its related hardware.

A ***roller vane electric fuel pump*** is a positive-displacement pump (each pump rotation moves a specific amount of fuel). It is normally located in the main fuel line. Look at **Figure 21-15.** Small rollers and an offset-mounted rotor disc produce fuel pressure.

When the rotor disc and rollers spin, they pull fuel in on one side of the pump. Then, the fuel is trapped and pushed to a smaller area on the opposite side of the pump housing. This squeezes the fuel between the rollers, and the fuel flows out under pressure.

Figure 21-14. Exploded view of an in-tank pump shows parts that can be removed for service. Fuel hoses, pump motor, and a strainer or low-pressure filter can be removed and replaced. (Mazda)

A ***sliding vane electric fuel pump*** is similar to a roller vane pump. However, it uses vanes of rollers.

Most rotary electric fuel pumps also have check valves and relief valves, **Figure 21-13** and **21-15.** The ***check valves*** keep fuel from draining out of the fuel line when the pump is not running. A ***relief valve*** limits the maximum output pressure of the pump.

A ***reciprocating electric fuel pump*** has the same basic action as a mechanical fuel pump. However, it uses a solenoid instead of a rocker arm to produce a pumping motion. This is not a common type of original equipment pump.

Electric Fuel Pump Circuit

A circuit for an electric fuel pump is shown in **Figure 21-16.** Study the electrical connections. Note that this circuit has a switch controlled by oil pressure. The ***oil pressure switch*** is a safety feature that protects the engine from damage by shutting off the fuel pump if the oil pressure is low. The engine will stop running a few seconds after the fuel pump is shut off. The oil pressure switch also acts as a bypass to the fuel pump relay, allowing the vehicle to start when the relay is faulty. This normally results in an extended crank time.

Fuel Supply System Service

Now that you have a basic understanding of how a fuel supply system functions, you are ready to learn about problems, tests, and repairs common to the parts.

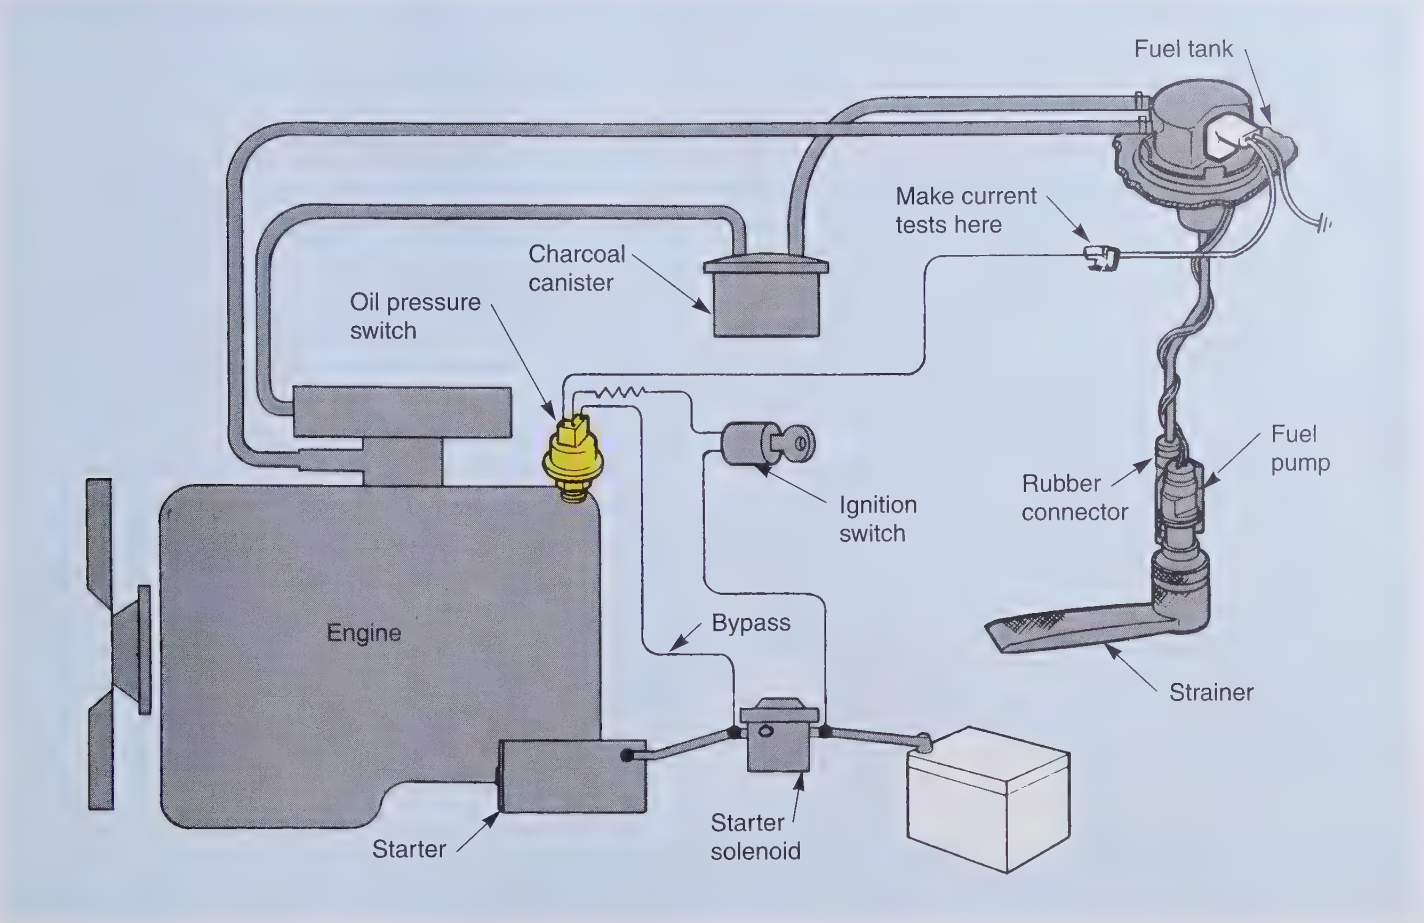

Figure 21-16. A typical electric fuel pump circuit with oil pressure switch. If the engine oil pressure drops too low, the switch shuts off the fuel pump. Note other connections and parts of the circuit. (Ford)

Warning!
Always keep a fire extinguisher handy when working on a car's fuel system. During a fire, a few seconds wasted looking for an extinguisher can be a *lifetime!*
Never weld or solder a fuel tank. If not badly rusted, a leaking tank should be sent to a well-trained specialist. Even an empty tank can *explode.* The heat produced during soldering or welding operations can cause fuel gum to melt, vaporize, and ignite.

Fuel Supply Systems Scanning

Depending on the symptoms, you will often want to scan for diagnostic trouble codes before starting fuel supply system repairs. Vehicles equipped with OBD II systems may monitor fuel tank pressure, fuel line pressure, fuel level, and other conditions. A scan tool will quickly let you find any stored codes. Modern scanners also display operating values (voltage, current, resistance) for the electrical circuit, which can speed troubleshooting.

Fuel Tank Service

Typical ***fuel tank problems*** include fuel leakage, physical damage (dents, holes, etc.), and contamination (rust, dirt, and water). Vibration or rusting can cause a fuel tank to develop pinhole leaks. Rocks can puncture the tank. Internal deterioration of the tank or foreign matter in the fuel can cause contamination problems.

Fuel Tank Removal and Replacement

A fuel tank can be located under the trunk floor, in a body panel, or under the rear seat. It can be held in the vehicle by large metal straps or by bolts passing through the tank flange. With rear-engine vehicles, the fuel tank can be located in the front.

Before servicing a fuel tank, make sure you empty the tank. A full tank is very heavy and can rupture if dropped.

To remove fuel from the tank, unscrew the drain plug and drain the fuel into an approved safety can. If a drain is *not* provided, use an approved pumping method to draw the fuel out of the tank.

With modern vehicles, you can normally use the in-tank or inline fuel pump to empty the tank, **Figure 21-17.** Disconnect the fuel hose at the main fuel line. Route it into an approved gas can. Turn the ignition key on and allow the fuel pump to force the fuel from the tank into the can. If the control module shuts the pump off after a few seconds, use a jumper wire to connect voltage directly to the pump terminal to allow for complete draining.

Warning!
Wipe up fuel spills immediately with a shop rag. Do *not* spread oil absorbent on fuel spills, because the oil absorbent will become extremely flammable.

After draining, you can remove the tank from the vehicle. Disconnect the filler neck, fuel lines, wires, and other components. Then, remove straps or bolts securing the tank to the body. Slowly lower the tank without dropping or hitting it.

When installing a fuel tank, make sure you replace the rubber insulators. Check that all fuel lines are properly secured. Replace the fuel in the tank and check for leaks. If needed, a service manual for the vehicle will detail tank installation procedures.

Fuel Tank Sending Unit Service

A *faulty fuel tank sending unit* can make the fuel gauge reading inaccurate. Usually, the variable resistor in the sending unit fails. However, you should remember that the fuel gauge or the gauge circuit may be at fault.

First, test the fuel gauge. **Figure 21-18** shows a fuel gauge tester. It is connected to the wire going to the fuel gauge feed wire. When the tester is set on *full*, for example, the fuel gauge should read *full*.

If the gauge does not function, either the gauge or the gauge circuit is faulty. If the fuel gauge begins to work with the tester in place, the tank sending unit is bad.

If your tests indicate an inoperative tank sending unit, remove the unit after draining the tank. Unscrew the cam lock or screws holding the sending unit in the fuel tank, **Figure 21-19.** If you do not have a special cam tool, use a drift punch and light hammer blows to rotate the lock tabs, **Figure 21-20.** Lift the unit out of the tank.

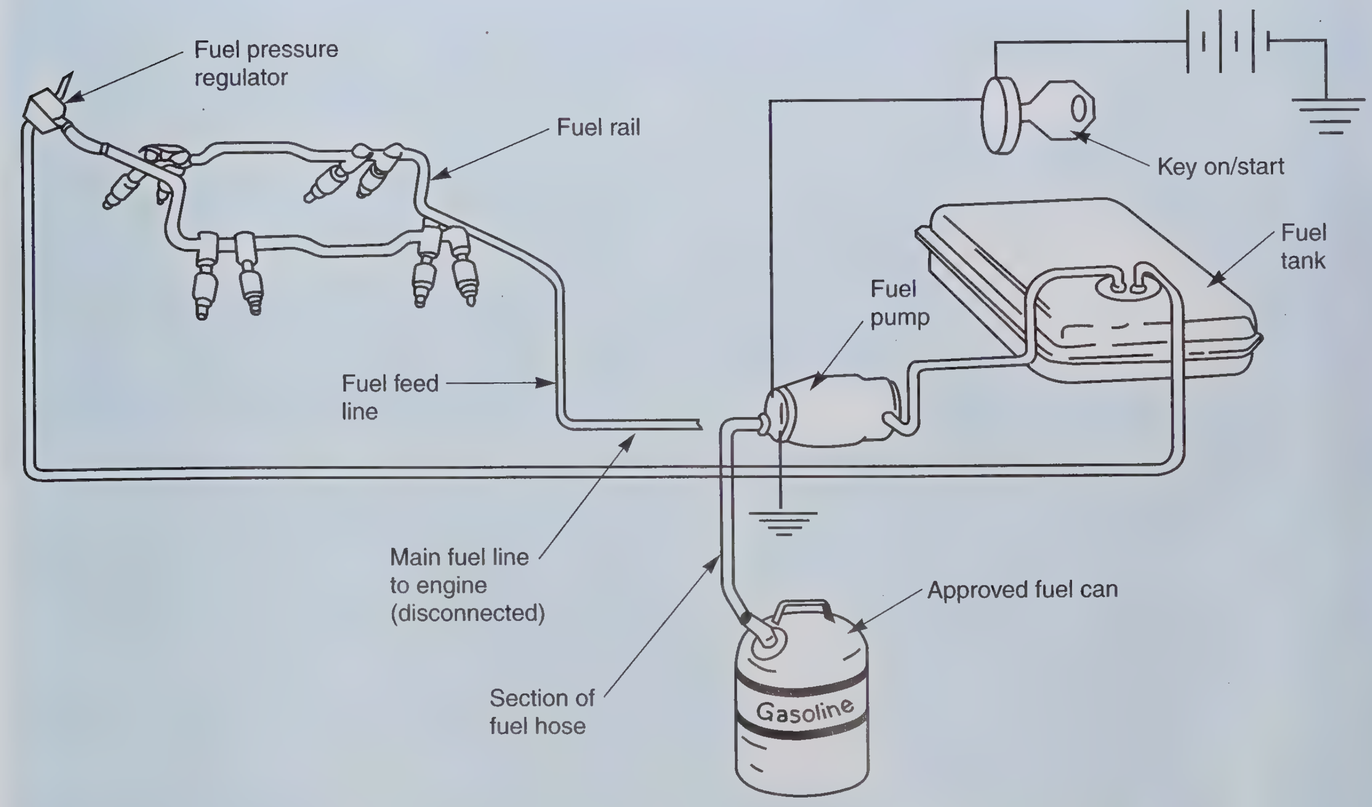

Figure 21-17. With electric fuel pumps, you can use the in-tank or inline pump to drain gasoline out of the tank. Connect a long hose from the pump outlet to an approved fuel can. Energize the pump and make sure fuel does not spill out.

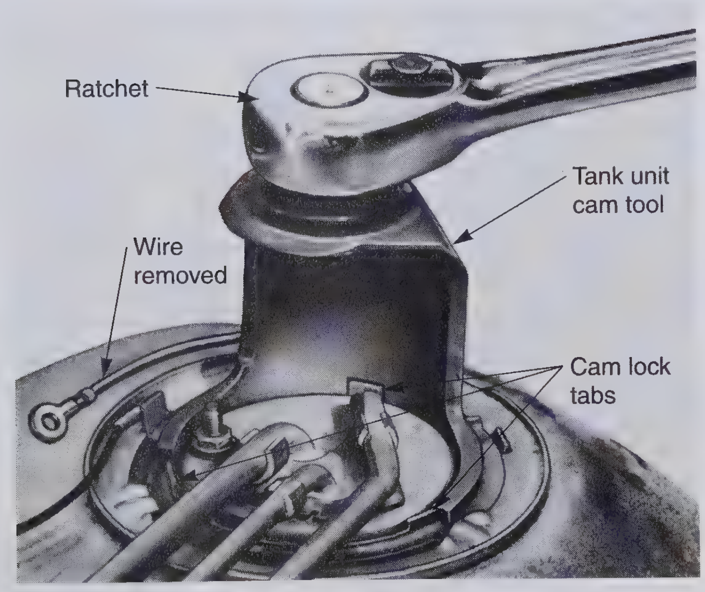
Figure 21-18. A tester will check the condition of the fuel gauge and the circuit. If the circuit and the gauge are working well, the problem may be in tank sending unit. Note how the sending unit is held in the fuel tank by a lock ring. (DaimlerChrysler)



Ratchet
Tank unit cam tool
Wire removed
Cam lock tabs

Figure 21-19. To remove the tank sending unit, turn the cam lock ring. A cam tool makes this easy. Light taps with a hammer on a drift punch will also work. (Cadillac)

With the sending unit removed, measure its resistance with an ohmmeter, **Figure 21-21.** If the resistance is not within the factory specifications, install a new sending unit.

Also, check the float for leakage. Shake the float next to your ear. If you can hear liquid splashing, replace the float. If the tank unit resistance is correct, check the tank ground. A poor ground could prevent gauge operation.

Fuel Line and Hose Service

Faulty fuel lines and hoses are common sources of fuel leaks. Fuel hoses can become hard and brittle after being exposed to engine heat and the environment. Engine oil softens and swells hoses. Always inspect hoses closely and replace any in poor condition. See **Figure 21-22.**

Metal fuel lines seldom cause problems. However, they should be replaced when smashed, kinked, rusted, or leaking.

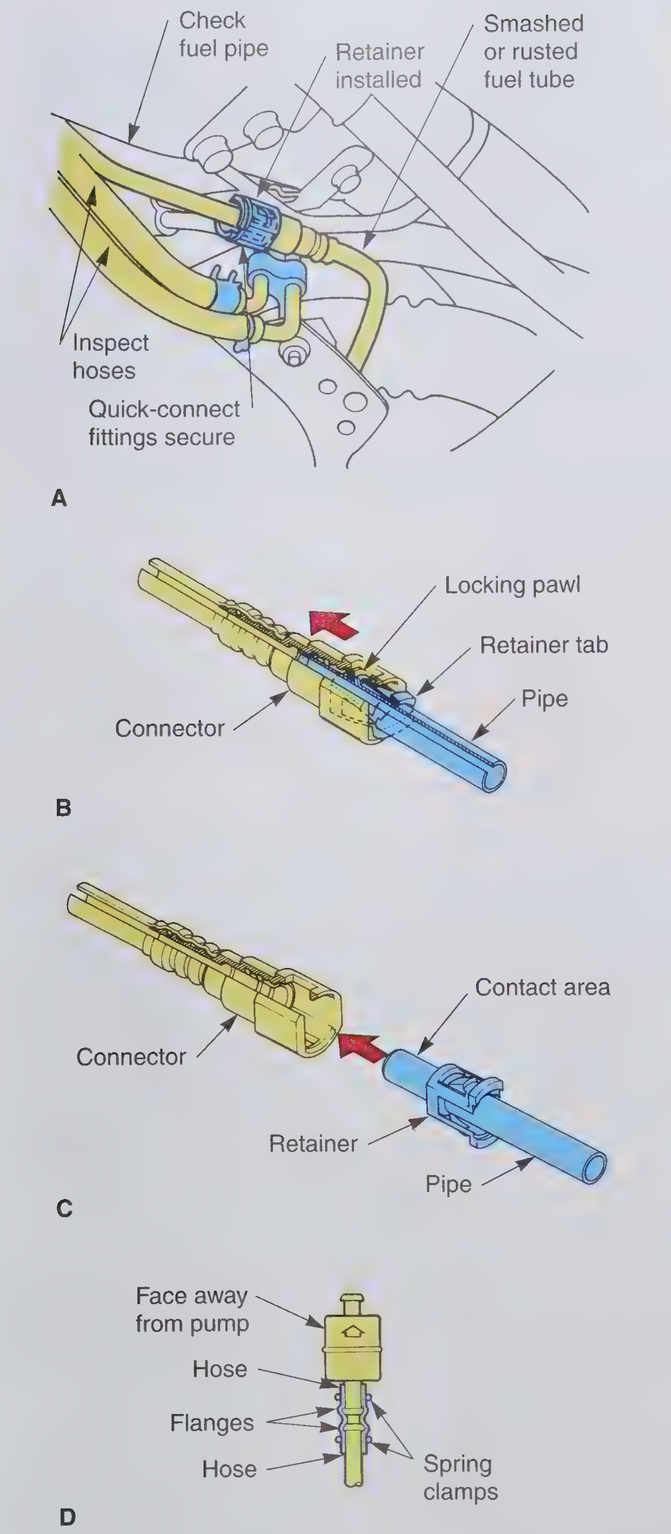

Figure 21-22. A—Always inspect fuel lines, hoses, and fittings for leakage and damage. Pay special attention to plastic lines. B—To disconnect this fuel line fitting, press down on the locking tab while pulling apart. C—To reconnect fitting, simply push the two halves of the fitting together. D—When installing fuel hoses, make sure they are completely over raised areas on the fuel line. Clamps should be on pressure side of flanges. (Honda and DaimlerChrysler)

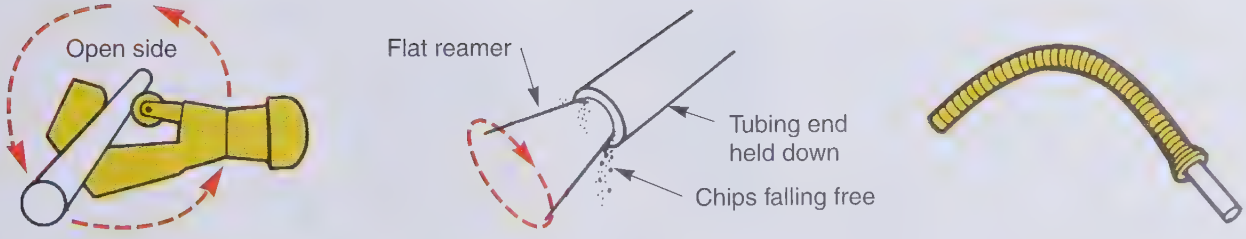
Caution!
Some late-model fuel lines have snap-type fittings. Do not try to pry the fittings apart or they will be damaged. Use a special fuel line fitting tool to release the fittings for service. This tool can be purchased at most auto part stores.

Fuel Line and Hose Service Rules

Remember these rules when working with fuel lines and hoses:

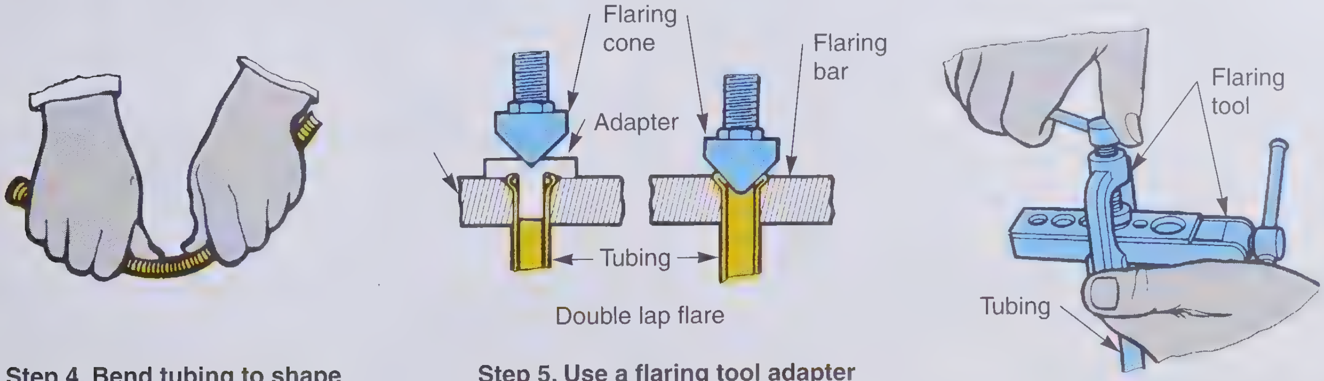
- Place a shop rag around the fuel line fitting during removal. This will keep fuel from spraying on you or on the hot engine. Use a flare nut or tubing wrench on fuel system fittings.
- Only use approved double-wall steel tubing for fuel lines. Never use copper or plastic tubing, unless it is OEM equipment.
- Make smooth bends when forming a new fuel line. Use a bending spring or bending tool.
- Form double-lap flares on the ends of the fuel line. A single-lap flare is not approved for fuel lines. Refer to **Figure 21-23.**
- Reinstall fuel line hold-down clamps and brackets. If not properly supported, the fuel line can vibrate and fail.
- Route all fuel lines and hoses away from hot or moving parts. Double-check clearance after installation.
- Route plastic fuel lines in their original locations. They are more prone to damage from engine heat and abrasion than metal lines.
- A plastic line will kink if bent too sharply. This will restrict fuel flow and may cause the line to fail in service.
- Use a factory-recommended tool to release clip-type fittings used to secure plastic fuel lines.
- If a plastic line or fitting is damaged, replace it with a new one. Do not attempt repairs, such as inline splices.
- Do not use non-OEM plastic tubing to repair fuel systems. The line pressure rating and the composition of the plastic may be different. The incorrect plastic line can rupture and cause a serious fire.
- Plastic lines tend to stiffen in service. Avoid bending or rerouting used plastic lines.
- Always cover plastic fuel lines with a wet towel when welding, torch cutting, or grinding near them. If a hot piece of metal melts the line, a serious fire can result.



Step 1. Cut tubing with tube cutter.

Step 2. Remove burrs.

Step 3. Slip bender over tubing.



Step 4. Bend tubing to shape of old fuel line.

Step 5. Use a flaring tool adapter to fold the tube end inward.

Step 6. Tighten flaring tool into tubing.

Figure 21-23. Fuel lines need double-lap flares. Study basic steps for making a new fuel line. This procedure also applies to other lines (brake lines, steel vacuum lines, etc.). (Florida Dept. of Voc. Ed. and DaimlerChrysler)

- Never allow battery acid to contact a metal or plastic fuel line. Lines can be weakened or eaten away by acid.
- Use only approved synthetic rubber hoses in a fuel system. If vacuum-type rubber hose is accidentally used, the fuel can chemically attack and rapidly ruin the hose. A dangerous leak could result.
- Make sure a fuel hose fully covers its fitting or line before installing the clamps. Pressure in the fuel system could force the hose off if it is not installed properly.
- When servicing press-fit fuel line fittings, you may need to replace the O-ring seal to prevent dangerous fuel leakage. Make sure you purchase the correct seal. If you install the wrong seal, a fire can result.
- Double-check all fittings for leaks. Start the engine and inspect the connections closely.

Warning!
Most fuel injection systems produce very high fuel pressure. Many systems maintain this pressure even after the engine is shut off. Follow recommended procedures for releasing pressure before disconnecting a fuel line or fitting. This will prevent fuel spray from possibly causing injury or a fire!

Fuel Filter Service

Fuel filter service involves periodic replacement or cleaning of system filters. It may also include locating clogged fuel filters that are upsetting fuel system operation.

A ***clogged fuel filter*** can restrict the flow of fuel to the pressure regulator, gasoline injectors, diesel injection pump, or carburetor. Engine performance problems will usually show up at higher cruising speeds.

With a clogged fuel filter, the engine may temporarily lose power or stall when a specific engine speed is reached. This is due to the flow restriction caused by a partially clogged filter. A partially clogged filter may pass enough fuel at low engine speeds. However, when engine speed and fuel requirements increase, the engine may "starve" for fuel.

On modern vehicles, a ***clogged in-tank strainer*** is a common and difficult-to-diagnose problem. When clogged, the in-tank filter can collapse and stop all fuel flow. Then, after the engine stalls, the strainer can open again, leaving no trace of a restriction.

Some fuel filters have a check valve that opens when the filter becomes clogged. This allows fuel contaminants to flow into the system. When contaminants are found in the filters and system, the tank, pump, and lines should be flushed with clean fuel.

Fuel Filter Locations

Fuel filters may be found in the following locations:

- In the fuel line before the fuel rail, fuel injectors, diesel injection pump, or carburetor.
- Inside the fuel pump.
- In the fuel line right after the electric fuel pump.
- Under the fuel line fitting in the carburetor.
- In the fuel tank on the end of the fuel pickup tube.

When in doubt about fuel filter locations, refer to a service manual. It will give information about service intervals, cleaning, and replacement of all system filters.

Tech Tip!
If a fitting must be loosened when changing a fuel filter, use a flare nut wrench. Do not overtighten and strip the fitting when replacing the filter. Double-check that the fuel hose, if used, is fully installed over the fitting barbs.

Fuel Pump Service

Fuel pump problems are usually low fuel pressure, inadequate fuel flow, abnormal pump noise, or fuel leakage from the pump.

Low fuel pump pressure can be caused by worn pump bearings, high resistance in electric pump circuit, leaking check valves, or physical wear of moving parts. Low fuel pump pressure can make the engine starve for fuel at higher engine speeds.

High fuel pump pressure, more frequent with electric pumps, indicates an inoperative pressure relief valve. If the relief valve fails to open, both pressure and volume can be above normal. A faulty fuel pressure regulator can also cause high fuel pressure. This can produce a rich fuel mixture or even flood the engine.

Mechanical fuel pump noise (clacking sound from inside pump) is commonly caused by a weak or broken rocker arm return spring, wear of the rocker arm pin, or wear of the arm itself. Mechanical fuel pump noise can be easily confused with valve or tappet clatter. They sound very similar. To verify mechanical fuel pump noise, place a stethoscope on the pump body. The point of the loudest noise is the source of the problem.

Most electric fuel pumps make some noise (buzz or whirl sound) when running. Only when the pump noise is abnormally loud should an electric fuel pump be considered faulty. A clogged tank strainer can also cause excessive pump noise. Pump speed can increase because fuel is not entering the pump properly.

Fuel pump leaks are caused by physical damage to the pump body or deterioration of the diaphragm or gaskets. Inline electric pump leaks are usually from the inlet and outlet hoses.

Most mechanical fuel pumps have a small vent hole in the pump body. When the diaphragm is ruptured, fuel will leak out of this hole.

It is possible for a ruptured mechanical fuel pump diaphragm to contaminate the engine oil with gasoline. Fuel can leak through the diaphragm, through the pump, into the side of the block, and down into the oil pan. When a gasoline smell is noticed in the oil, correct the pump problem; then change the oil and filter.

Fuel Pump Tests

Fuel pump testing commonly involves measuring fuel pump pressure and volume. Exact procedures vary, depending on fuel system type. Refer to a manual for exact testing methods. Sometimes, fuel pump vacuum is measured as another means of determining pump and supply line condition.

Always remember there are several other problems that can produce symptoms like those caused by a faulty fuel pump. Before testing a fuel pump, check for:

- Restricted fuel filters.
- Smashed or kinked fuel lines or hoses.
- Air leak into vacuum side of pump or line.
- Injection system or carburetor troubles.
- Ignition system problems.
- Low engine compression.

Measuring Fuel Pump Pressure

To measure fuel pump pressure:

1. Connect a pressure gauge to the output line of the fuel pump or to the appropriate test fitting, **Figure 21-24.** Modern fuel injected engines normally have a test fitting on the engine fuel rail.
2. To test a mechanical fuel pump, start the engine and allow it to idle at the specified rpm. To test an electric fuel pump, you may need to activate (supply voltage to) the pump motor or start the engine.
3. Compare your pressure readings to specifications.

Tech Tip!
With fuel injection, you are also testing the fuel pressure regulator, not just the pump.

Fuel pressure for a gasoline injection system can run from 15–40 psi (100–280 kPa). A diesel supply pump should produce around 6–10 psi (40–70 kPa). It feeds fuel to the high-pressure injection pump. Fuel pressure

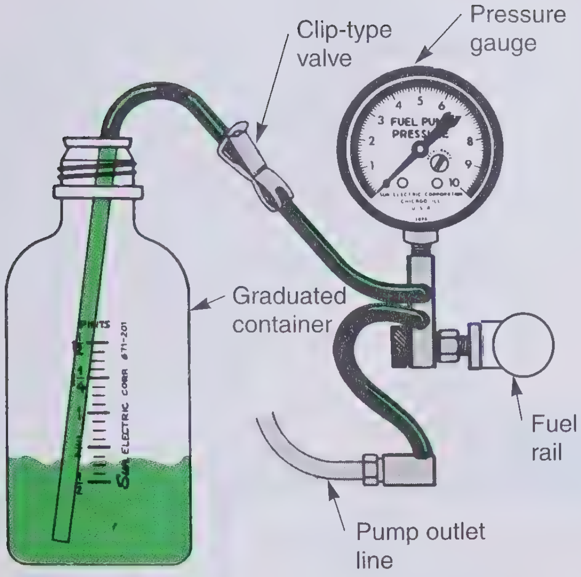


Figure 21-24. To test fuel pump pressure and volume, connect test equipment as shown. Connect a gauge to the fuel line before the fuel manifold, throttle body, or carburetor. Close the clip and start the engine to measure pressure. Open the clip to measure volume over a prescribed time span. (DaimlerChrysler)

for a carburetor-type fuel system should be about 4–6 psi (30–40 kPa).

Always remember to use factory values when determining fuel pump condition. Pressures vary from system to system.

If fuel pump pressure is *not* within specifications, check pump volume and the lines and filters before replacing the fuel pump. Also, isolate the fuel pressure regulator from the pump. This can be done by pinching the fuel hose going to the fuel return line or by taking the regulator out of the system.

If needed, you can also connect the pressure gauge directly to the output of the electric fuel pump. This will take the pressure regulator, feed lines, and other parts out of the system for isolating the problem.

Measuring Fuel Pump Volume

Fuel pump volume, also called ***fuel pump capacity,*** is the amount of fuel the pump can deliver in a specific amount of time. It is measured by allowing fuel to pour into a graduated (marked) container for a certain time period.

To check fuel pump volume:

1. Route the output line from the fuel pump into a graduated container, **Figure 21-24.** For safety, a valve or clip should be used to control fuel flow into the container.
2. With the engine idling at the specified speed, allow fuel to pour into the container for the prescribed amount of time (normally 30 seconds).
3. Close off the clip or valve, and shut off the engine.
4. Compare volume output (amount of fuel in the container) to specifications.

Fuel pump volume output should be a minimum of one pint (0.47 liters) in 30 seconds for carburetor systems. Fuel injection systems typically have a slightly higher volume output from the supply pump. Refer to factory service manual values for the particular fuel pump and automobile.

Measuring Fuel Pump Vacuum

Fuel pump vacuum should be checked when a fuel pump fails pressure and volume tests. A vacuum test will rule out possible problems in the fuel lines, hoses, filters, and pickup screen.

For example, a clogged fuel pickup screen could make the fuel pump fail the volume test. If the same pump passes a vacuum test, you need to check the lines and filters for problems.

To measure fuel pump vacuum:

1. Connect a vacuum gauge to the inlet side of the pump, **Figure 21-25.**
2. Leave the fuel hose in your graduated container from the volume test.
3. Open the valve and activate the pump (start engine and allow to run on fuel in carburetor or connect voltage to electric pump).
4. Compare your vacuum reading to specifications.

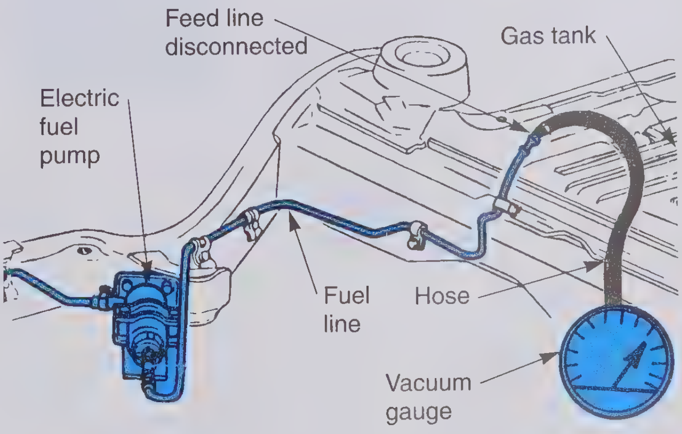

Figure 21-25. Fuel pump vacuum specifications are sometimes given. Connect vacuum gauge to inlet of inline pump and compare to specifications. (Cadillac)

Typically, ***fuel pump vacuum*** should be about 7–10 in. Hg. A good vacuum reading indicates a good fuel pump. If the pump failed the pressure or volume test but passed the vacuum test, the fuel supply lines or filters may be at fault.

Electric Fuel Pump Circuit Tests

Many electric fuel pump problems are caused by electrical circuit problems, **Figure 21-26.** Broken wires, bad relays, shorts, blown fuses, computer malfunctions, and other troubles can affect electric fuel pump operation.

If an electric fuel pump does *not* pass its pressure or volume tests, measure the amount of voltage being fed to the pump motor. Look at **Figure 21-27.** If supply voltage is low, there is a problem in the electrical circuit to the pump.

When circuit problems must be found, use the service manual and your knowledge of basic electrical testing

procedures. Generally, test the circuit at various points until the source of the trouble is found. **Figure 21-28** shows a wiring diagram for one electric fuel pump circuit. Note that there are only a few components and connections that could upset pump operation. Make sure to check the electric fuel pump relay if power is not reaching the pump, **Figure 21-29.**

Fuel Pump Shutoff Circuits

An ***inertia switch*** can be used to block current flow to the electric fuel pump after a severe impact or collision. It is a safety device that can prevent a serious fire after an auto accident. The inertia switch is usually located in the trunk or near the electric fuel pump. After a collision, you must press a button on the inertia switch before the electric pump will function again.

A ***oil pressure switch*** can be used to shut off the electric fuel pump if engine oil pressure drops too low. Its circuit is designed to protect the engine from major mechanical damage.

Fuel Pump Removal and Replacement

When a fuel pump does *not* pass its performance tests, it must be removed and replaced or rebuilt. To

remove a mechanical fuel pump, simply disconnect the fuel lines and unbolt the pump from the engine. If needed, lightly tap the side of the pump with a plastic hammer to free the gasket. See **Figure 21-30.**

An electric fuel pump may be located in the main fuel line or in the fuel tank. With an inline pump, simply disconnect the fuel fittings and remove the pump, **Figure 21-31.** An in-tank pump must usually be removed as part of the tank sending unit. This procedure was described earlier in the chapter.

Some vehicles provide an in-tank ***fuel pump access door*** in the trunk so you do not have to remove the fuel tank to service the pump. By removing the small screws that hold the access door in place, you can service the in-tank pump more easily. If the electric pump is mounted on the top of the tank and no access door is provided, you will have to remove the tank to service the fuel pump.

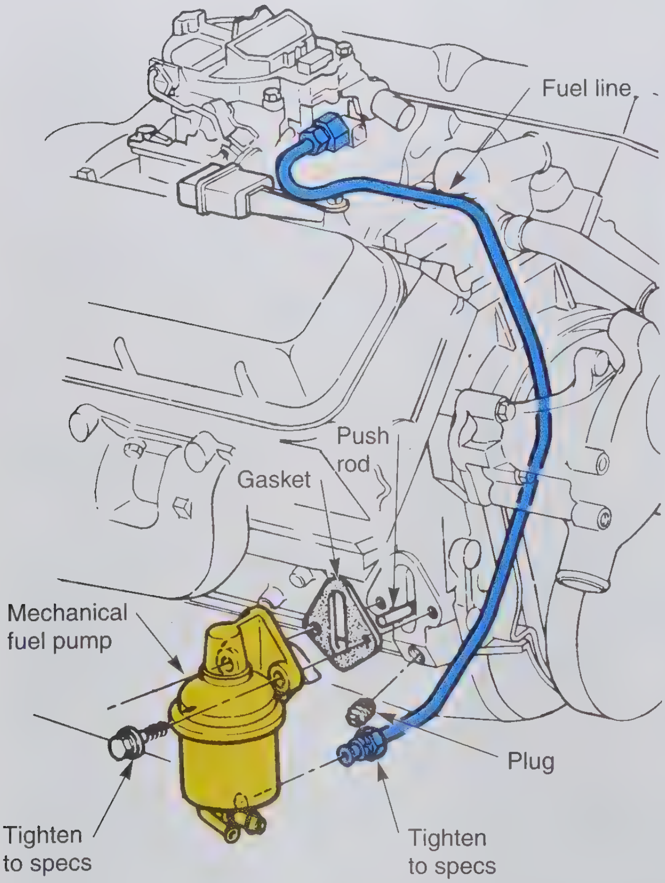

Figure 21-30. To service a mechanical fuel pump, remove lines and hoses. Then remove pump-to-block fasteners. Use a new gasket when installing. Torque fasteners to specifications. (Chevrolet)

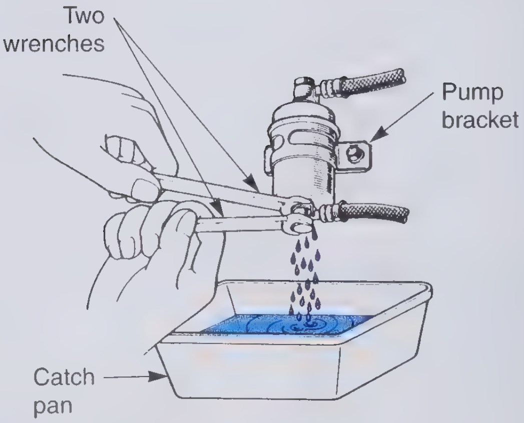

Figure 21-31. When removing an electric fuel pump, use two wrenches if needed to prevent line or fitting damage. Place a catch pan under the pump to prevent fuel spillage. (Toyota)

Fuel Pump Rebuilding

Older mechanical fuel pumps are held together with screws and can be overhauled if parts are available. Normally, when either a mechanical or electric fuel pump is bad, it is replaced with a new pump.

Tech Tip!

When installing a mechanical fuel pump, position the camshaft eccentric *away* from the pump rocker arm. This will make it much easier to hold the pump against the engine while starting the bolts. If a push rod is used, coat it with heavy grease. Then, push it up into place. This will hold the push rod out of the way while you install the mechanical fuel pump.

Air Filter Service

An ***air filter,*** or ***air cleaner,*** removes foreign matter (dirt and dust) from the air entering the engine intake manifold. Most air filters use a paper ***element*** (filter material). The element fits inside a metal or plastic housing. See **Figure 21-32.**

Air filter service usually involves replacing or cleaning the filter element. Paper filter elements are usually replaced with a new unit. When replacing a filter element, you should also wipe out the filter housing. Dirt can collect in the bottom of the housing. Look at **Figure 21-33.**

Be careful not to drop anything into the air inlet opening in the intake mainfold engine. As a precaution, place a clean shop rag over the engine's air inlet.

Workplace Skills

A *comeback* is a vehicle that is returned to the shop by an unsatisfied customer. To satisfy the unhappy customer, the shop may need to repair the vehicle again, free of charge. An excessive number of comebacks will damage a shop's reputation and reduce its profits. A shop may take disciplinary action against technicians who create comebacks through careless work. Therefore, it is important to perform all repairs carefully.

Summary

- A fuel supply system draws fuel from the fuel tank and forces it into the fuel metering device (gasoline injectors, diesel injection pump, or carburetor on older vehicles).
- Fuel tank capacity is the volume of fuel a fuel tank can hold. An average fuel tank capacity is 12–25 gallons (45–95 liters).

- A tank pickup-sending unit extends down into the tank to draw out fuel and to operate the fuel gauge.
- A fuel return system helps cool the fuel and prevents vapor lock (bubbles form in overheated fuel and stop fuel flow).
- An electric fuel pump, like a mechanical pump, produces fuel pressure and flow for the fuel metering section of a fuel system.
- The oil pressure switch is a safety feature that protects the engine from damage by shutting off the fuel pump when oil pressure is dangerously low.
- Typical fuel tank problems include fuel leakage, physical damage (auto accidents), and contamination by foreign matter (rust, dirt, and water).
- To remove fuel from the tank, unscrew the drain plug and drain the fuel into an approved safety can. If a drain is *not* provided, use an approved pumping method to draw the fuel out of the tank.
- A faulty fuel tank sending unit can make the fuel gauge reading inaccurate. With a clogged fuel filter, the engine may temporarily lose power or stall when a specific engine speed is reached.
- Low fuel pump pressure can be caused by worn, dragging pump bearings, high resistance in electric pump circuit, leaking check valves, or physical wear of moving parts.
- Fuel pressure in a gasoline injection system can run from 15–40 psi (100–280 kPa). A diesel supply pump should produce around 6–10 psi (40–70 kPa). Fuel pressure in a carburetor-type fuel system should be about 4–6 psi (30–40 kPa).
- Fuel pump volume, also called capacity, is the amount of fuel the pump can deliver in a specific amount of time.
- An inertia switch can be used to block current flow to the electrical fuel pump after a severe impact or collision.
- Some vehicles provide an in-tank fuel pump access door in the trunk so you do not have to remove the fuel tank to service the pump.

Review Questions—Chapter 21

Please do not write in this text. Place your answers on a separate sheet of paper.

1. List and describe the three subsystems of a modern fuel system.
2. A(n) ______ ______ system draws fuel from the fuel tank and forces it to the fuel metering device.
3. An average fuel tank capacity is around 12–25 gallons (45–95 liters). True or False?
4. What is the purpose of a filler neck restrictor in a fuel tank assembly?
5. Which of the following is *not* part of a fuel tank pickup-sending unit?
   (A) Vapor separator.
   (B) In-tank fuel strainer or filter.
   (C) Variable resistor.
   (D) Pickup tube.

6. Fuel lines are normally made of single-wall steel tubing. True or False?
7. When are fuel hoses needed?
8. Explain the operation of a fuel return system.
9. The following is *not* used as a fuel filter.
   (A) Pleated paper filter.
   (B) Sintered iron filter.
   (C) Bowl filter.
   (D) Foam filter.
10. The two basic types of fuel pumps are the _____ and _____ types.
11. Explain the difference between the two types of fuel pumps in Question 10.
12. The _____ _____ controls fuel pressure in a mechanical fuel pump.
13. During the intake stroke of a mechanical fuel pump, the camshaft's eccentric pushes on the pump rocker arm. True or False?
14. Can a mechanical fuel pump idle? Explain.
15. Define the term "vapor lock."
16. Where can electric fuel pumps be located?
17. Which of the following is an advantage of an electric fuel pump?
   (A) Instant fuel pressure.
   (B) Very little pressure pulsations.
   (C) Helps prevent vapor lock.
   (D) All of the above.
18. Rotary type electric fuel pumps include the _____, _____ _____, and _____ _____ types.
19. A(n) _____ _____ limits the maximum output pressure of an electric fuel pump.
20. Why is an oil pressure switch sometimes used in an electric fuel pump circuit?
21. List nine service rules for fuel lines and hoses.
22. Name five typical fuel filter locations.
23. Fuel pump pressure for a gasoline injection system should be approximately _____ to _____ psi or _____ to _____ kPa.
24. During an electric fuel pump test, where can you connect your pressure gauge to eliminate the pressure regulator from the circuit?
   (A) Pump inlet.
   (B) Pump outlet.
   (C) Fuel rail.
   (D) None of the above.
25. What is a fuel pump volume test?

ASE-Type Questions

1. Which of the following is *not* one of the three fuel system subsystems?
   (A) Cooling system.
   (B) Air supply system.
   (C) Fuel supply system.
   (D) Fuel metering system.
2. Which of the following is a fuel metering device?
   (A) Carburetor.
   (B) Gasoline injector.
   (C) Diesel injection pump.
   (D) All of the above.
3. Which of the following are placed inside fuel tanks to prevent fuel splashing?
   (A) Caps.
   (B) Filters.
   (C) Baffles.
   (D) Restrictors.
4. When bubbles form in overheated fuel and prevent fuel flow, it is called:
   (A) blowby.
   (B) vapor lock.
   (C) fuel blocking.
   (D) condensation.
5. Which of the following are used to stop contaminants from entering parts that could be damaged by foreign matter?
   (A) Fuel filters.
   (B) Pleated paper elements.
   (C) Sintered bronze elements.
   (D) All of the above.
6. A mechanical fuel pump is powered by a(n):
   (A) pull rod.
   (B) eccentric.
   (C) rocker arm.
   (D) outlet valve.
7. Each of these is an electric rotary fuel pump *except:*
   (A) vacuum.
   (B) impeller.
   (C) roller vane.
   (D) sliding vane.

8. When performing fuel tank repairs, Technician A believes, for safety reasons, leaks should never be mended by welding or soldering. Technician B agrees, but says any fuel tank leak repair should be handled strictly by a specialist. Who is right?
   (A) *A only.*
   (B) *B only.*
   (C) *Both A and B.*
   (D) *Neither A nor B.*
9. Fuel filters are located:
   (A) *in the fuel line.*
   (B) *in the fuel pump.*
   (C) *under the fuel line.*
   (D) *All of the above.*
10. Fuel pressure for a typical fuel injection system should be about:
    (A) *4–6 psi.*
    (B) *6–10 psi.*
    (C) *15–40 psi.*
    (D) *28–41 psi.*
11. Which of the following can be used to block current flow to an electric fuel pump after a severe collision?
    (A) *Hose clamp.*
    (B) *Inertia switch.*
    (C) *Fusible resistor.*
    (D) *Fuel pump relay.*
12. To remove a mechanical fuel pump, do each of these *except:*
    (A) *disconnect fuel lines.*
    (B) *unbolt pump from engine.*
    (C) *remove diaphragm spring.*
    (D) *free gasket with plastic hammer.*

Activities—Chapter 21

1. Prepare a “tree diagnosis chart” for a fuel pump problem assigned by your instructor. Your resources will be a shop manual for the specific vehicle and your instructor. If your instructor requests it, present the procedure to the class using an overhead projector and sketches.
2. Review electrical principles of resistance in a circuit and explain with sketches how a thermostatic fuel gauge works.

Fuel Delivery System Diagnosis

Condition	Possible Cause	Correction
No fuel delivery.	1. No fuel.	1. Add fuel to the tank.
	2. Tank filter clogged.	2. Replace tank filter.
	3. Fuel lines kinked or clogged.	3. Straighten or clean fuel lines.
	4. Vapor lock.	4. Cool fuel lines. Change to less volatile fuel. Protect fuel lines from heat.
	5. Fuel pump inoperative.	5. Replace pump.
	6. Fuel filter or filters clogged.	6. Replace filters.
	7. Frozen fuel line.	7. Thaw and remove water from the fuel system.
	8. Air leak between fuel pump and tank.	8. Repair leak.
	9. Clogged injectors.	9. Clean or replace injectors, locate source of deposits.
	10. Inoperative injection pump (diesel).	10. Repair or replace pump.
Insufficient fuel delivery.	1. Tank filter partially clogged.	1. Replace filter.
	2. Gas lines kinked or clogged.	2. Straighten or clean fuel lines.
	3. Vapor lock.	3. Cool fuel lines. Change to less volatile fuel. Protect fuel lines from heat.
	4. Air leak between fuel pump and tank.	4. Repair air leak.
	5. Fuel filter partially clogged.	5. Replace filter.
	6. Defective fuel pump.	6. Replace pump.
	7. Insufficient voltage reaching fuel pump.	7. Repair fuel pump circuit.
	8. Wrong pump.	8. Install correct pump.
	9. Clogged injection pipes.	9. Clean or replace pipes.
	10. Defective injectors.	10. Clean or replace injectors.
	11. Faulty injection pump (diesel).	11. Rebuild or replace pump.
	12. Fuel injection pulse width incorrect.	12. Check control module and sensors. Replace as needed.
	13. Mass airflow sensor malfunction.	13. Replace mass airflow sensor.
	14. Defective oxygen sensor.	14. Replace oxygen sensor.
Excessive fuel delivery or pressure.	1. Defective fuel pump.	1. Replace pump.
	2. Incorrect pump.	2. Replace pump.
	3. Fuel injection pulse width excessive.	3. Check control module and sensors. Replace as needed.
	4. Fuel injection pressure regulator malfunctioning.	4. Adjust or replace pressure regulator.
	5. Engine control module defective.	5. Replace control module.
	6. Mass airflow sensor malfunction.	6. Replace mass airflow sensor.
	7. Defective oxygen sensor.	7. Replace oxygen sensor.

22

Gasoline Injection Fundamentals

After studying this chapter, you will be able to:

- List some of the possible advantages of gasoline injection.
- Describe the classifications of gasoline injection.
- Explain the operation of electronic throttle body gasoline injection.
- Explain the operation of electronic multiport gasoline injection.
- Summarize the operation of airflow-sensing, hydraulic-mechanical (continuous), and pressure-sensing gasoline injection systems.
- Compare the various types of gasoline injection systems.
- Correctly answer ASE certification test questions on gasoline injection systems.

This chapter introduces the operating principles of gasoline injection systems. Specific systems vary, but many of the parts—such as sensors, fuel injectors, and control modules—are very similar. This chapter provides a broad background in the many gasoline injection systems found on today's vehicles. However, electronic multiport fuel injection is the main focus of the chapter, since it is the most common gasoline injection system.

Gasoline Injection Fundamentals

A typical ***gasoline injection system*** uses pressure from an electric fuel pump to spray fuel into the engine's intake manifold. See **Figure 22-1.** Like a carburetor, the gasoline injection system must provide the engine with the correct air-fuel mixture for specific engine operating conditions. Unlike a carburetor, however, the injection system uses *pressure,* not engine *vacuum,* to feed fuel into the engine. This makes a gasoline injection system very efficient.

Gasoline Injection Advantages

A gasoline injection system has several advantages over a carburetor-type fuel system. A few of these include:

- Improved atomization. Fuel is forced into the intake manifold under pressure, which helps break fuel droplets into a fine mist.

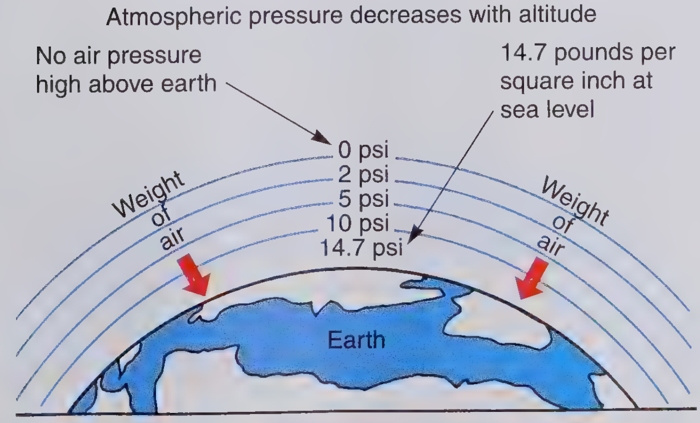
- Better fuel distribution. There is a more equal flow of fuel vapors into each cylinder.
- Smoother idle. A lean fuel mixture can be used without rough idle because of better fuel distribution and low-speed atomization.
- Improved fuel economy. Higher efficiency results from more precise fuel metering, atomization, and distribution.
- Lower emissions. A lean, efficient air-fuel mixture reduces exhaust pollution.
- Better cold-weather driveability. Injection provides better control of mixture enrichment than a carburetor choke.
- Increased engine power. Precise metering of fuel to each cylinder and increased airflow can result in more horsepower output.
- Simpler. Electronic fuel injection systems have fewer parts than computer-controlled carburetor systems.

Atmospheric Pressure

Atmospheric pressure is the pressure formed by the air surrounding the earth. At sea level, the atmosphere exerts 14.7 psi (103 kPa) of pressure on everything. This pressure is caused by the weight of the air, as shown in **Figure 22-2.**

Vacuum

A ***vacuum*** is lower than atmospheric pressure in an enclosed area. Suction is another word for vacuum. Any space with less than 14.7 psi (103 kPa) of pressure at sea level has a vacuum.



Atmospheric pressure decreases with altitude

Weight of air
Weight of air
Earth

Figure 22-2. Atmospheric pressure is produced by the weight of air. Pressure changes with altitude. Atmospheric pressure is what moves air and fuel mixture into cylinders on intake strokes.

Differences in Pressure Cause Flow

A difference in pressure between two areas can be used to cause flow. For instance, when you suck on a straw, atmospheric pressure pushes down on the liquid in the glass. This causes the liquid to flow through the straw and into the vacuum in your mouth. An engine uses differences in pressure to force fuel and air into its cylinders. The engine acts as a vacuum pump, producing a low-pressure area, or vacuum, in the intake manifold. See **Figure 22-3.**

Engine Throttle Valve

The ***engine throttle valve*** controls airflow and gasoline engine power output. It is a "butterfly" or flap-type valve in the throttle body assembly. When closed, the throttle valve restricts the flow of air and the resulting flow of fuel into the engine. This keeps engine speed and power low for ***idling.***

When the driver presses on the accelerator, or "gas pedal," to increase engine speed, the throttle cable slides inside its housing. This swings the throttle valve open. Atmospheric pressure then pushes more air into the engine intake manifold. Engine sensors detect the resulting changes and increase fuel flow through the injectors. With more air and fuel entering the cylinders, the pressure produced on the power strokes is increased. Engine speed and horsepower output then increase to accelerate the vehicle.

When the accelerator is released, a throttle return spring pulls the throttle valve closed. This returns the engine to idle speed. **Figure 22-4** shows how a vehicle's accelerator and throttle cable control the throttle valve.

Drive-by-Wire System

Instead of a mechanical cable or linkage, a ***drive-by-wire system*** uses a pedal sensor, a control module, and an actuator to operate the engine throttle valve on a gasoline engine (or the fuel injection pump on a diesel engine). When you press on the accelerator, the pedal moves a variable resistor. The control module measures current flow through the resistor and calculates how far the pedal is depressed. It then sends a signal to the actuator to control engine speed.

The benefit of drive-by-wire systems is that they can gradually increase power to prevent undue strain on the driveline and reduce fuel consumption. Even if the accelerator is tromped to the floor, the control module can slowly increase engine speed for better efficiency.

Gasoline Injection Classifications

There are many types of gasoline injection systems. Before studying the most common ones, you should have a basic knowledge of the different classifications of gasoline injection. This will help you understand the similarities and differences between systems.

A gasoline injection system is commonly called a ***fuel injection system.*** To avoid confusion, remember that a diesel injection system is also a fuel injection system. The two are quite different, however.

Throttle Body and Multiport Injection

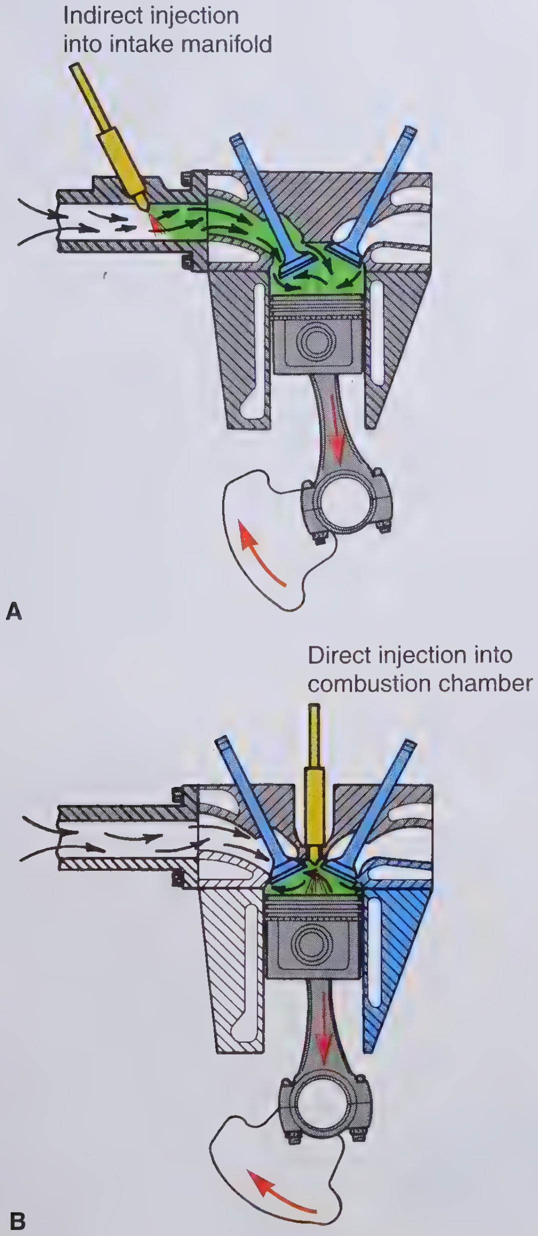
The location, or point, of fuel injection is one way to classify a gasoline injection system. In a ***throttle body injection system,*** the injector nozzles are mounted in a throttle body assembly located on top of the engine. Fuel is sprayed into the top center of the intake manifold. Throttle body injection is illustrated in **Figure 22-1A.**

A ***multiport injection system*** has fuel injectors in the ***intake ports*** (air-fuel runners or passages going to each cylinder). See **Figure 22-1B.** Gasoline is sprayed into each intake port, toward each intake valve. One injector is provided for each engine cylinder.

Multiport injection systems control the air-fuel mixture more precisely than throttle body systems, lowering emissions and increasing power output. Therefore, these systems are used in all late-model vehicles.

Indirect and Direct Injection

An ***indirect injection system*** sprays fuel into the engine intake manifold. Most gasoline injection systems are indirect systems. A ***direct injection system*** forces fuel into the engine combustion chambers. All diesel injection systems are direct systems. Both indirect and direct injection systems are shown in **Figure 22-5.**



Indirect injection into intake manifold
A
Direct injection into combustion chamber
B

Figure 22-5. A—Indirect injection sprays fuel into the intake manifold. Gasoline injection systems are usually this type. B—Direct injection sprays fuel into the combustion chambers.

Gasoline Injection Controls

There are three common methods used to control the amount of gasoline injected into the engine. These are electronic controls, hydraulic controls, and mechanical controls.

Electronic fuel injection uses various engine sensors and a control module to regulate the opening and closing of the fuel injectors. This is the most common type of gasoline injection system. It is covered in detail later in this chapter.

Hydraulic fuel injection utilizes pressure-vacuum operated control devices moved by air or fuel pressure. The hydraulic control system uses an airflow sensor and a fuel distributor to meter gasoline into the engine. A ***fuel distributor*** is a hydraulic valve mechanism that meters fuel into the engine.

Mechanical fuel injection uses throttle linkage, a mechanical pump, and a governor speed device to control injection volume. This is a very old, seldom-used type of injection system found mainly on high-performance gasoline and diesel engines. Diesel systems are covered in later chapters.

Gasoline Injection Timing

The ***timing*** of a gasoline injection system links the engine valve action to the time when fuel is sprayed into the engine. There are three basic classifications of gasoline injection timing. These are intermittent, timed, and continuous.

An ***intermittent gasoline injection system*** opens and closes the injection valves independent of the engine intake valves. This type of injection system may spray fuel into the engine when the valves are open or when they are closed. Another name for an intermittent injection system is ***modulated injection system.***

A ***timed injection system*** squirts fuel into the engine right before or as the intake valves open. The best example of timed injection is a diesel injection system. Most modern multiport gasoline injection systems are also timed for improved efficiency.

A ***continuous gasoline injection system*** sprays fuel into the intake manifold at all times. Anytime the engine is running, some fuel is forced out of the injector nozzles and into the engine. The air-fuel ratio is controlled by increasing or decreasing fuel pressure at the injectors. This type of system is discussed near the end of this chapter.

Injector Opening Relationship

Simultaneous injection means that all the injectors in an engine open at the same time. The injectors are pulsed *on* and *off* together. ***Sequential injection*** means that the injectors open one after the other. ***Group injection*** has several injectors opening at the same time. For example, a V-8 engine might have one group of four injectors that open at one time and another group of four that open at a different time.

Electronic Fuel Injection

An electronic fuel injection (EFI) system can be divided into four subsystems:

- Fuel delivery system.
- Air induction system.
- Sensor system.
- Computer control system.

These four subsystems are illustrated in **Figure 22-6. Figure 22-7** shows the major parts of a complete fuel injection system.

Fuel Delivery System

The ***fuel delivery system*** of an EFI system includes an electric fuel pump, a fuel filter, a pressure regulator, fuel injectors (injector valves), and connecting lines and hoses. See **Figure 22-8.**

The ***electric fuel pump*** draws gasoline out of the tank and forces it into the pressure regulator. The ***fuel pressure regulator*** controls the amount of pressure entering the injector valves. When sufficient pressure is attained, the regulator returns excess fuel to the tank. This maintains a preset amount of fuel pressure for injector operation. Engine vacuum is ported into the fuel pressure regulator. This allows the pressure regulator to lower fuel pressure slightly at idle speed (low engine load) and increase it with higher engine speed (higher engine load). Look at **Figures 22-9 and 22-10.**

A ***fuel injector*** for an EFI system is simply a coil- or solenoid-operated fuel valve, **Figure 22-11.** When not energized, spring pressure holds the injector closed, keeping fuel from entering the engine. When current flows through the injector coil, the magnetic field attracts the injector armature and the injector valve opens. Fuel then squirts into the intake manifold under pressure. See **Figure 22-12.**

Air Induction System

An ***air induction system*** for an EFI system typically consists of an air filter, throttle valves, sensors, and connecting ducts. **Figure 22-13** pictures the air induction system for one type of EFI-equipped engine.

Airflow enters the inlet duct and flows through the air filter. The air filter traps dust and debris and prevents it from entering the engine. Plastic ducts then route the clean air into the throttle body assembly. The throttle body assembly in multiport injection systems simply

contains the throttle valve and idle air control device. After leaving the throttle body, air flows into the engine intake manifold. The manifold is divided into runners (passages) that route the air to each cylinder head intake port.

Sensor system

The ***EFI sensor system*** monitors engine operating conditions and sends information about these conditions to the control module. See **Figure 22-14.** An ***engine sensor*** is an electrical device that changes its electrical output (resistance, voltage, or current) with a change in a condition, such as temperature, pressure, or position. For example, a temperature sensor's resistance may decrease as temperature increases. The control module analyzes the increased current flow through the sensor to determine if a change in injector valve opening is needed.

Computer control system

The ***computer control system*** uses electrical data from the sensors to control the operation of the fuel injectors and other engine performance-related devices. A wiring harness connects the sensors to the input of the computer (control module). Another wiring harness connects the output of the computer to the fuel injectors. Refer to **Figure 22-15.**

Figure 22-15. Sensors feed information to the control module. The control module uses this data to operate other system components. (Ford)

The ***engine control module*** is the "brain" of an electronic fuel injection system. Refer to **Figure 22-16.** It is a preprogrammed microcomputer. The control module uses sensor inputs to calculate when and how long to open the fuel injectors. To open an injector, the control module completes, or closes, the circuit between the battery and the injector coil. To close the injector, the module disconnects, or opens, the circuit between the battery and the injector coil.

Engine Sensors

Typical sensors for an EFI system include:

- Oxygen sensor.
- Manifold absolute pressure (MAP) sensor.
- Throttle position sensor.
- Engine coolant temperature sensor.
- Airflow sensor.
- Intake air temperature sensor.
- Crankshaft position sensor.

Oxygen Sensor

An ***oxygen sensor,*** also called an ***exhaust gas sensor,*** measures the oxygen in the engine's exhaust gases as a means of checking combustion efficiency. OBD I (and older) vehicles use one oxygen sensor located in the exhaust manifold or exhaust pipe before the catalytic converter. Look at **Figures 22-17** and **22-18.**

Vehicles with OBD II use at least two oxygen sensors—one before the catalytic converter and one after the catalytic converter. See **Figure 22-19.** The primary sensor is located before the catalytic converter and is used to monitor the oxygen content of the exhaust gases entering the converter. The secondary oxygen sensor, or catalyst monitor, is located after the catalytic converter. It monitors the oxygen content of the gases leaving the converter to determine how well the catalyst elements are working.

Secondary
O2 sensor
Primary
O2 sensor

Figure 22-19. With OBD II systems, two oxygen sensors are used to more closely monitor exhaust emissions. The first oxygen sensor is called the primary oxygen sensor. The second oxygen sensor is called the secondary oxygen sensor.

The voltage output of the oxygen sensor varies with changes in the oxygen content of the exhaust. For example, an increase in oxygen from a lean mixture makes the sensor output voltage decrease. A decrease in oxygen from a rich mixture causes the sensor output to increase. In this way, the sensor supplies data on oxygen content to the computer. The computer can then alter the opening and closing of the injectors to adjust the air-fuel ratio for maximum efficiency.

Note!
Some oxygen sensors do not produce an output voltage. Instead, they vary their internal resistance as the oxygen content of the exhaust changes. For detailed information on both types of oxygen sensors, refer to Chapter 43, *Emission Control Systems.*

Open Loop and Closed Loop

When in ***open loop,*** the electronic fuel injection system does *not* use engine exhaust gas content as a main indicator of the air-fuel mixture. Instead, the system operates on preprogrammed information stored in the computer. See **Figure 22-20A.**

For example, right after cold engine starting, the computer operates in open loop. Several sensors, especially the oxygen sensor, *cannot* provide accurate information before the engine reaches normal operating temperature. The computer is set to ignore these sensor inputs when the engine is cold.

Closed loop means that the computer is using information from the oxygen sensor and the other sensors. This information forms an imaginary loop, or circle, from the computer, through the fuel system, into the exhaust system, and back to the computer, **Figure 22-20B.**

After the catalytic converter and oxygen sensor(s) heat up, an electronic gasoline injection system functions in closed loop. This lets the computer double-check the fuel mixture it is providing to the engine.

Manifold Absolute Pressure Sensor

A ***manifold absolute pressure (MAP) sensor*** measures the pressure, or vacuum, inside the engine intake manifold. Manifold pressure is an excellent indicator of engine load. High pressure (low intake vacuum) indicates a high load, requiring a rich mixture. Low manifold pressure (high intake vacuum) indicates very little load, requiring a leaner mixture. The manifold pressure sensor varies resistance with changes in engine load. This data is used by the computer to alter the fuel mixture, **Figure 22-21.**

Throttle Position Sensor

A ***throttle position sensor*** is a variable resistor connected to the throttle plate shaft. Look at **Figure 22-22.** When the throttle opens or closes, the sensor changes resistance and signals the computer. The computer can then richen or lean the mixture as needed.

Engine Coolant Temperature Sensor

An ***engine coolant temperature sensor*** monitors the operating temperature of the engine. It is mounted so that it is exposed to the engine coolant. When the engine is cold, the sensor might provide a low resistance (high current flow). The computer would then richen the air-fuel mixture for cold engine operation. When the engine warms, the temperature or coolant sensor resistance changes so the computer knows to make the mixture leaner.

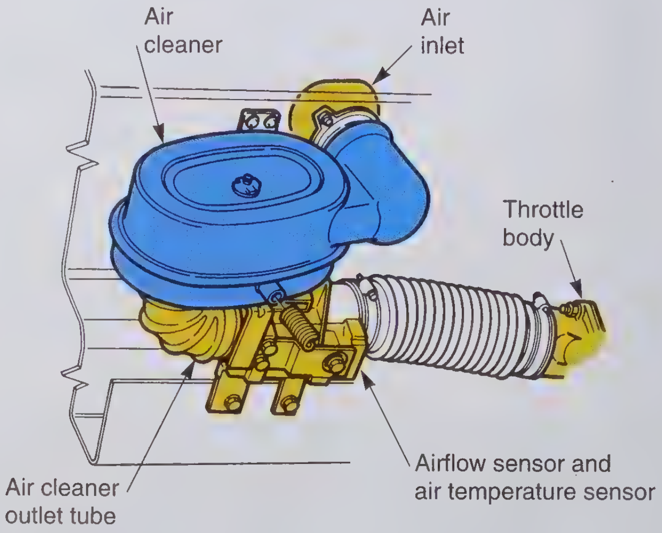
The control module can then alter the fuel mixture for idle and wide open throttle positions. (Honda)

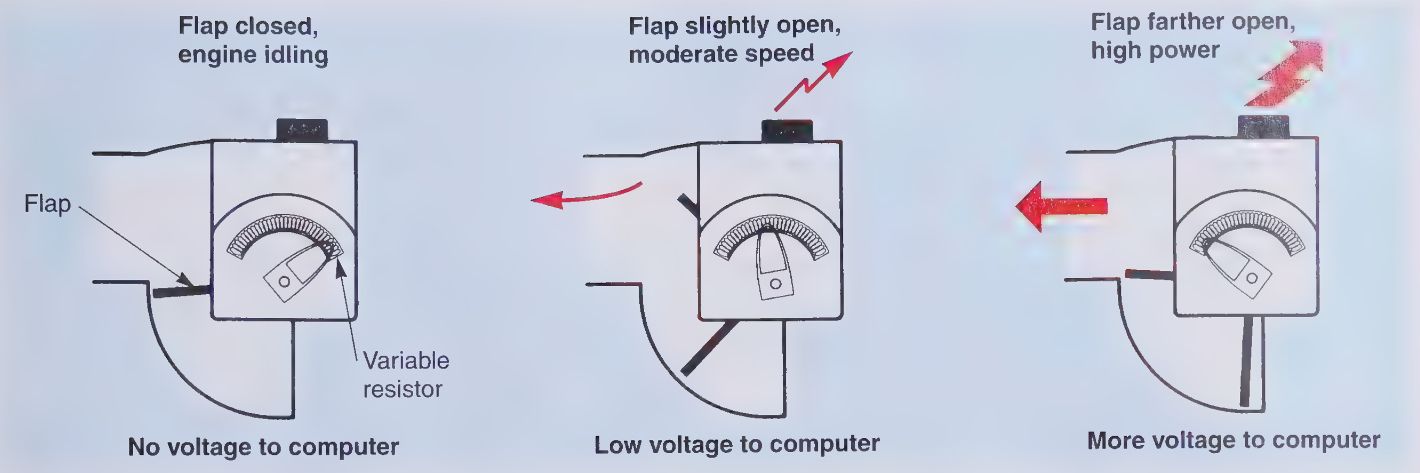


Air cleaner
Air inlet
Throttle body
Air cleaner outlet tube
Airflow sensor and air temperature sensor

Figure 22-23. The airflow sensor and the intake air temperature sensor are housed under the air cleaner on this engine. (Ford)

Airflow Sensor

An ***airflow sensor*** is used in many EFI systems to measure the amount of outside air entering the engine. This helps the computer determine how much fuel is needed. Refer to **Figure 22-23.** The airflow sensor usually contains an air flap or door that operates a variable resistor, **Figure 22-24.** Increased airflow opens the flap more, changing the position of the variable resistor. Information is then sent to the computer indicating air inlet volume.



Flap closed, engine idling
Flap slightly open, moderate speed
Flap farther open, high power
Flap
Variable resistor
No voltage to computer

More voltage to computer

Figure 22-24. This airflow sensor operates a variable resistor. Low airflow at idle does not open the sensor flap, and resistance stays high. As airflow increases, the flap swings open, decreasing sensor resistance and increasing current flow to the control module. (VW)

Intake Air Temperature Sensor

An ***intake air temperature sensor*** measures the temperature of the air entering the engine. Cold air is more dense than warm air, requiring more fuel for the proper ratio. The intake air temperature sensor helps the computer compensate for changes in outside air temperature and maintain an almost perfect air-fuel mixture ratio.

Crankshaft Position Sensor

A ***crankshaft position sensor*** is used to detect engine speed. Refer to **Figure 22-14A.** It allows the computer to change injector timing and duration with changes in engine rpm. Higher engine speeds generally require more fuel.

Other Sensors

Other sensors can also be used to affect the operation of a fuel injection system. These include an A/C compressor sensor, transmission sensors, EGR sensor, vehicle speed sensor, and engine knock sensor. They provide additional data about operating conditions affecting engine fuel needs.

Analog and Digital Signals

The signal from the engine sensors can be either digital or analog. ***Digital signals*** are on-off signals. An example of a sensor providing a digital signal is the Hall-effect crankshaft position sensor, which monitors engine rpm. Voltage output or resistance goes from maximum to minimum almost instantly.

An ***analog signal*** changes in strength to let the computer know about a change in a condition. For example, the internal resistance of a sensor may smoothly increase or decrease with changes in temperature, pressure, or part position. The sensor acts as a variable resistor.

Injector Pulse Width

The ***injector pulse width*** indicates the amount of time each injector is energized and kept open. The computer

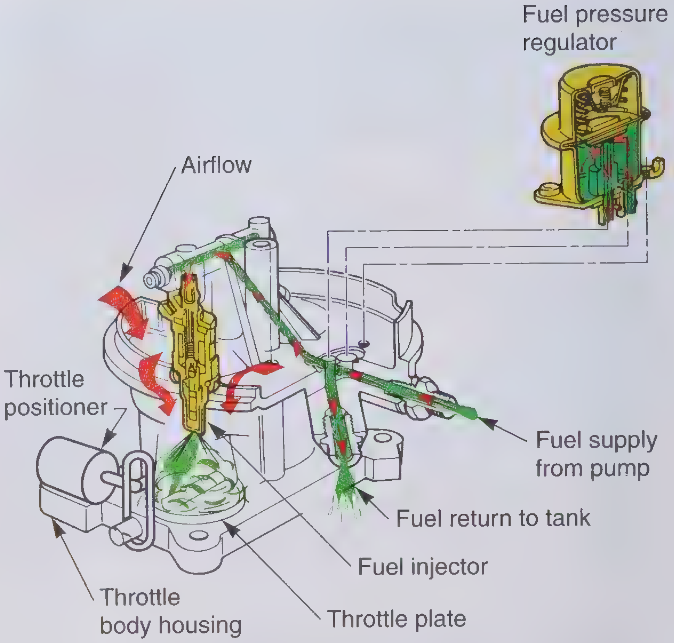
Figure 22-25. Pulse width is used to control the amount of fuel injected into the engine. A longer pulse width richens the mixture. A shorter pulse width leans the mixture.

controls the injector pulse width. **Figure 22-25** shows how pulse width controls injector output. Study the drawing carefully!

Under full acceleration, the computer will sense a wide-open throttle, low intake manifold pressure, and high inlet airflow. The computer then lengthens the injector pulse width to richen the mixture for more power. Under low power conditions, the computer shortens the injector pulse width. With the injectors being closed a larger percentage of time, the air-fuel mixture is leaner and better fuel economy is achieved.



Fuel pressure regulator
Airflow

Fuel injector
Throttle body housing
Throttle plate

Figure 22-27. Fuel enters the throttle body from the pump. It then enters the pressure regulator before passing into the injector. Fuel sprays out of the injector and mixes with air entering the air horn. (Ford)

Throttle Body Injection

A ***throttle body injection system (TBI)*** uses one or two injector valves mounted in a throttle body assembly. A diagram of an injector and its control circuits is shown in **Figure 22-26.** The injector(s) spray fuel into the top of the throttle body air horn. The fuel spray mixes with the air flowing through the air horn. The mixture is then pulled into the engine by intake manifold vacuum.

TBI Assembly

The ***TBI assembly***, **Figure 22-27,** typically consists of:

- ***Throttle body housing***—this is the metal casting that holds the injectors, fuel pressure regulator, throttle valves, and other parts.
- ***Fuel injector***—a solenoid-operated fuel valve mounted in the upper section of the throttle body assembly.
- ***Fuel pressure regulator***—a spring-loaded bypass valve that maintains constant pressure at the injectors.
- ***Throttle positioner***—a motor assembly that opens or closes the throttle plates to control engine idle speed.

- ***Throttle position sensor***—a variable resistor that senses opening or closing of the throttle plates.
- ***Throttle plates***—butterfly valves that control airflow through the throttle body.

TBI Throttle Body Housing

The TBI ***throttle body housing*** bolts to the pad on the intake manifold. Throttle plates are mounted in the lower section of the housing. A linkage mechanism or cable connects the throttle plates with the accelerator. An inlet fuel line connects to one fitting on the throttle body housing. An outlet return line to the tank connects to another fitting on the housing.

TBI injector

A ***throttle body injector*** consists of the electric solenoid coil, armature or plunger, ball or needle valve, ball or needle seat, and injector spring. These parts are pictured in **Figure 22-28** and on the right in **Figure 22-29.** Wires from the engine control module connect to the terminals on the injectors. When the ECM energizes the injectors, a magnetic field is produced in the injector coil. The magnetic field pulls the plunger and valve up to open the injector. Fuel can then squirt through the injector nozzle and into the engine.

Valve seat
Ball valve
Atomizer (nozzle)
Spray pattern

Figure 22-28. This TBI injector uses a ball-type valve instead of a pointed needle valve. Note the part names.

TBI Pressure Regulator

The ***throttle body pressure regulator*** consists of a fuel valve, diaphragm, and spring. When fuel pressure is low, such as when starting the engine, the spring holds the fuel valve closed. This causes pressure to build as fuel flows into the regulator from the electric fuel pump. Refer to **Figure 22-29.** When a preset pressure is reached, pressure acts on the diaphragm. The diaphragm compresses the spring and opens the fuel valve. Fuel can then flow back to the fuel tank. This limits the maximum fuel pressure at the injector(s).

Figure 22-29. This cutaway illustration shows the basic action inside a typical throttle body assembly. The regulator limits the maximum pressure inside the injector to a preset level. Then, the pulse width accurately controls the air-fuel ratio. The idle air control valve is used to increase or decrease idle speed. (Pontiac)

Engine Idle Speed Control

There are many different ways to provide a smooth engine idle under all operating conditions with fuel injection systems. The most common are the fast idle thermo valve and the idle air control motor or solenoid.

A ***fast idle thermo valve*** opens to increase idle speed when the engine is cold. It uses a thermowax plunger that expands when heated and contracts when cooled. Shown in **Figure 22-30,** the thermo valve opens when cold to allow air to bypass the throttle valve. This extra air increases engine idle speed to prevent cold engine stalling. As both the engine and thermo valve warm, the valve closes the bypass air off to return to a normal engine idle speed.

An ***idle air control motor*** may also be used to help control engine idle speed. It is a solenoid- or servo-motor-operated air bypass valve. It works something like the thermo valve, but it is computer controlled. See **Figure 22-31.**

The system's electronic control module opens the idle air control valve when temperature sensors signal a cold engine. This allows more air to enter the intake manifold, increasing idle speed to keep the engine from stalling. As the engine warms, the ECU gradually closes the valve, decreasing the amount of air that bypasses the throttle valve and reducing engine speed to curb idle (normal idle rpm).

Idle air control motors are used on both multiport and throttle body systems. They can be used to control both slow and fast idle speeds. See **Figure 22-32**.

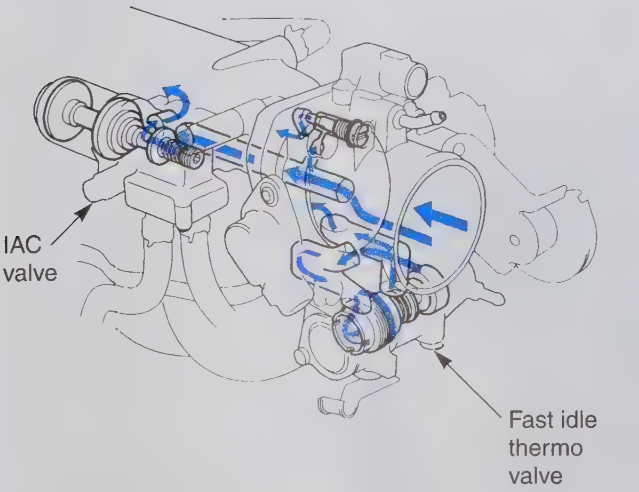

Figure 22-30. Note how the idle air control valve and the thermo valve can affect air that bypasses the throttle valve to alter engine idle speed. (Honda)

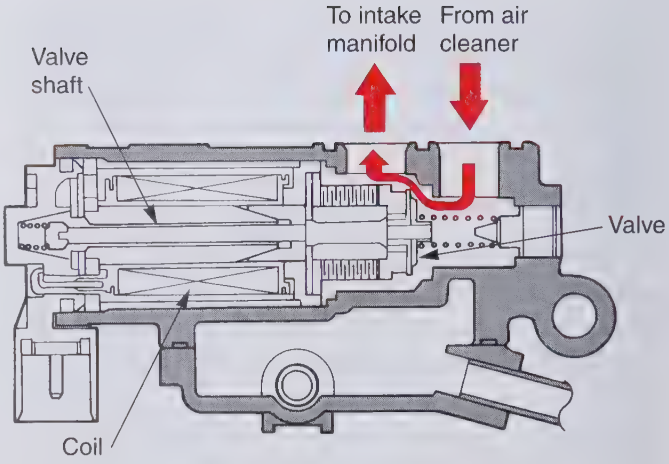

Figure 22-31. This cutaway shows the basic parts inside the idle air control motor. When the coil is energized, it attracts and pulls on the shaft to open the air valve. Spring tension pushes the valve closed when the coil is de-energized. (Honda)

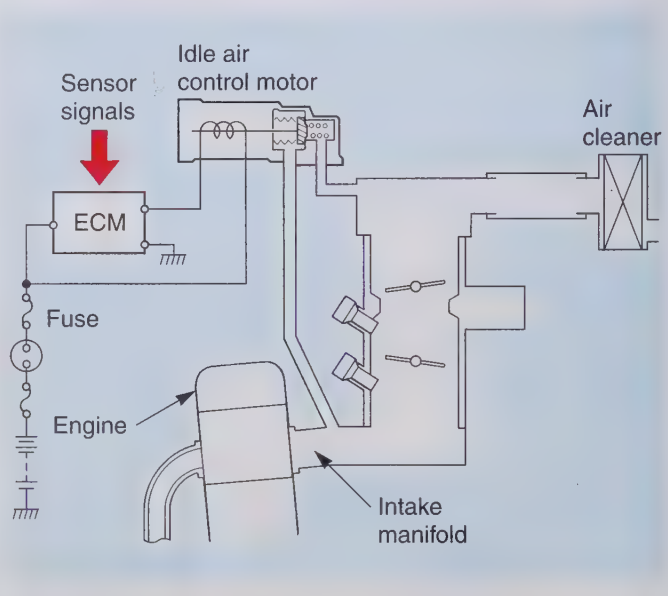

Figure 22-32. This diagram shows how the control module can open or close the idle air motor to affect engine idle speed. As more air bypasses the throttle valve, engine speed increases. This keeps the engine from stalling when cold. (Honda)

In addition to the idle air control motor, a throttle positioner is often used on throttle body assemblies to control engine idle speed. The computer actuates the positioner to open or close the throttle plates. In this way, the computer can maintain a precise idle speed with changes in engine temperature, load, and other conditions.

Continuous Throttle Body Injection

A ***continuous throttle body injection (CTBI)*** system sprays a solid stream of fuel into the air horn. Unlike the more common modulated system just discussed, it does *not* pulse the injectors on and off to control the air-fuel mixture. To increase or decrease fuel flow, the CTBI system alters the pressure applied to the nozzles in the throttle body. The system measures fuel flow, airflow, and other engine conditions. The computer then increases or decreases the speed of the ***control pump*** (fuel pump) to meet engine needs. The air cleaner and throttle body assembly of this type injection system contain the computer, airflow sensor, fuel control motor, ***spray bar*** or injector nozzles, and other components. This is not a commonly used system.

Electronic Multiport Injection

Electronic multiport injection systems use a computer, engine sensors, and one solenoid injector for each engine cylinder. This is the most common fuel injection system on late-model cars. Look at **Figure 22-33.** The operation of an electronic multiport system is similar to that of the modulated throttle body injection system covered earlier. However, fuel is injected at each intake port instead of at the plenum (top center of the intake manifold).

A ***multiport throttle body*** assembly contains the throttle plates and throttle position sensor, but does *not* contain the injector valves. See **Figure 22-34**. Its main function is to control airflow into the engine.

A ***multiport pressure regulator*** is mounted in the fuel line before or after the injectors, **Figure 22-35.** It performs the same function as the pressure regulator covered earlier. It maintains a constant pressure at the inlet to the injector valves by acting as a bypass branch.

A ***fuel rail*** feeds fuel to several of the injectors. It connects the main fuel line to the inlet of each injector, **Figure 22-36.**

EFI Multiport Injector

An EFI ***multiport injector valve*** is usually press fit into the runner (port) in the intake manifold. Each injector is aimed to spray fuel toward an engine intake valve(s). It is constructed something like an intermittent throttle body injector. **Figure 22-37** shows an EFI multiport injector. Study this illustration carefully. An EFI multiport injector typically consists of:

- ***Electric terminals***—these are electrical connections for completing a circuit between the injector coil and electronic control module.
- ***Injector solenoid***—an armature and coil assembly that opens and closes the needle valve.
- ***Injector screen***—a screen filter for trapping debris before it can enter the injector nozzle.
- ***Needle valve***—located on the end of the armature and seals against the needle seat.
- ***Needle seat***—a round hole in the end of the injector that seals against the needle valve tip.
- ***Injector spring***—a small spring that returns the needle valve to the closed position.
- ***O-ring seal***—a rubber seal that fits around the outside of the injector body and seals in the intake manifold.
- ***Injector nozzle***—the outlet of the injector that produces the fuel spray pattern.

There are several variations of electronic multiport injection. It is important that you understand the primary differences between each type system.

Air-Fuel Emulsion Injector

An ***air-fuel emulsion injector*** mixes air with the fuel creating a slurry. The slurry is then injected into the intake manifold. This helps atomize the fuel and improve combustion. One type of air-fuel emulsion injector is illustrated in **Figure 22-38.** Low pressure air from the air injection pump can be used to provide this air to the injector body.

Unitized Multiport Injection

Unitized multiport injection is a system that mounts all of the fuel injectors into a single assembly, **Figure 22-39.** For example, on a six-cylinder engine, all six injectors are housed in one enclosure on top of the engine plenum or intake manifold. One large multi-pin terminal connects each injector to its own control module or to the engine control module. The unitized injector unit is often mounted in rubber so it is isolated from engine vibration.

Plastic ***fuel injection transfer lines*** connect each injector in the unit to its poppet valve. One end of each line connects to the bottom of the fuel injector assembly. The other end connects to a poppet valve, **Figure 22-40.** A ***fuel injection poppet valve*** is simply a spring-loaded valve that prevents fuel leakage between injector pulses. It is normally closed. When one of the fuel injectors opens, fuel pressure overcomes poppet valve spring pressure and fuel sprays out the corresponding poppet valve. The mist of fuel enters the intake port and is pulled into the combustion chamber.

A ***unitized fuel injector*** is similar to an electronic multiport or port-mounted injector. However, it has a plastic hose fitting for the transfer line instead of a spray nozzle. It uses an electromagnetic coil to pull up on an armature to open the valve, allowing fuel injection. See **Figure 22-41.**

Injector Resistor Pack

An ***injector resistor pack*** is a set of low-ohm resistors that control current flow to each injector coil. They protect the injector windings from excess current. Each resistor is usually around 5–7 ohms. The injector resistor pack is often mounted in the engine compartment. **Figure 22-42** shows the basic circuit for a typical injector resistor pack.

Airflow-Sensing Multiport EFI

An ***airflow-sensing multiport EFI*** uses an airflow sensor as a main control of the system. As shown in **Figure 22-43,** an airflow sensor is placed at the inlet to the intake manifold. It and other engine sensors provide electrical data to the computer.

The airflow sensor is a flap-operated variable resistor, **Figure 22-44.** Airflow through the sensor causes an air door (flap) to swing to one side. Since the air door is connected to a variable resistor, the amount of airflow into the engine is converted into an electrical signal for the computer.

Airflow Sensor Operation

When the throttle valve is closed at idle, the airflow sensor's door remains almost closed. See **Figure 22-45.**

Figure 22-45. The throttle valve controls engine speed and power output. A—The throttle is almost closed. The engine is running slowly. The airflow sensor detects little airflow. The control module produces a short injection pulse width for a small injection quantity. B—The throttle is moved open for more power. Increased flow pushes the sensor flap open. The control module increases the pulse width for a richer mixture. (Nissan)

The computer then produces a short injector pulse width. Only a small amount of fuel is injected into the intake ports. When the driver presses the accelerator, the throttle plate swings open and airflow increases. The airflow door is pushed open, changing sensor resistance. The computer then increases injector pulse width for a richer mixture.

Pressure-Sensing Multiport EFI

Pressure-sensing multiport injection uses intake manifold pressure (vacuum) as a primary control of the system. Look at **Figure 22-46.** A pressure sensor is connected to a passage going into the intake manifold. The pressure sensor converts changes in manifold pressure into changes in electrical resistance or current flow. The computer uses this electrical data to calculate engine load and air-fuel ratio requirements.

Hydraulic-Mechanical Continuous Injection System

A ***hydraulic-mechanical continuous injection system (CIS)*** uses a mixture control unit to operate the injectors. A ***mixture control unit*** is an airflow sensor-fuel distributor assembly. **Figure 22-47** shows a diagram of this system. This is not an electronic system.

CIS Fuel Distributor

A ***fuel distributor*** is a hydraulically-operated valve mechanism that controls fuel flow or pressure to each CIS injector. The fuel control plunger is located in the center of the distributor. Fuel is fed from the plunger to spring-loaded diaphragms. The diaphragms compensate for pressure differences in each injection line. They help ensure that the same amount of fuel is sent to each injector.

Tech Tip!
A fuel distributor is used in only one type of CIS system, which is found on many foreign cars.

CIS Fuel Injectors

A ***CIS fuel injector*** is simply a spring-loaded valve. It injects fuel all the time when the engine is running. See **Figure 22-48.** A spring holds the valve in a normally closed position. A filter in the injector traps dirt. When

Figure 22-47. A hydraulic-mechanical injection system uses a mechanical airflow sensor to operate a hydraulic fuel distributor assembly. Note that a continuous injector is used to spray fuel into engine anytime the engine is running. (Robert Bosch)

the engine is cranked for starting, fuel pressure builds and pushes the injector valve open. A steady stream of gasoline then sprays toward each engine intake valve. The fuel is pulled into the engine when the intake valves open.

With CIS injectors, the quantity of fuel injected is controlled by increasing or decreasing fuel pressure to the injectors. The injector is usually push-fitted into plastic bushings in the cylinder head or intake manifold.

Cold Start Injector

A ***cold start injector*** is an additional fuel injector valve used to supply extra fuel for cold engine starting. Either a thermo-time switch or the system control module is used to operate the cold start injector. A cold start injector is used on some older-model vehicles. It is constructed like a conventional, solenoid type injector.

Cold Start Injector Operation

Figure 22-49 shows a basic cold start injector thermo-time switch circuit. When the sensor detects a cold engine, the switch closes to energize the cold start injector. The cold start injector and the other injectors all spray fuel into the intake manifold. Like a carburetor choke, this provides a very rich mixture to sustain cold engine operation.

Figure 22-48. A CIS injector is simply a spring-loaded valve. With enough fuel pressure, the injector valve opens and fuel sprays into the intake port of the engine.

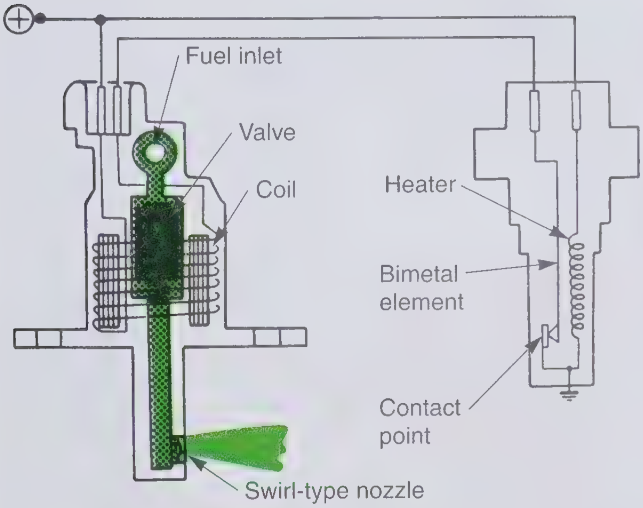

Figure 22-49. A basic cold start injector thermo-time switch circuit. The thermo-time switch energizes the cold start injector when engine temperature is low enough. The injector then sprays extra fuel into the engine to help keep the cold engine running smoothly. When the engine warms enough, the thermo-time switch opens to shut off the injector. A heating element in the switch ensures that the injector stays on for a short period of time, even if the engine is very cold.

Fuel Accumulator

A ***fuel accumulator*** can be used in a gaoline injection system to dampen pressure pulses. One is shown in **Figure 22-50.** The accumulator may also maintain pressure when the system is shut down. This aids engine restarting.

Industry Trend

Today's small cars have greatly improved fuel efficiency. Small but powerful engines squeeze more energy out of every drop of fuel. Electronic engine controls, lighter body/frame structures, and sleeker body shapes have all helped reduce fuel consumption, conserving our natural resources.

Summary

- A gasoline injection system uses pressure from an electric fuel pump to spray fuel into the engine intake manifold.
- Atmospheric pressure is the pressure formed by the air surrounding the earth. At sea level, the atmosphere exerts 14.7 psi (103 kPa) of pressure.
- The engine throttle valve controls airflow and engine power output.
- A throttle body injection system (TBI) has the injector nozzles in a throttle body assembly on top of the engine.
- A multiport injection system has fuel injectors in the air-fuel runners going to each cylinder.
- A timed injection system squirts fuel into the engine right before or as the intake valves open.
- A fuel injector for an EFI system is simply a coil- or solenoid-operated fuel valve.
- An engine sensor is an electrical device that changes circuit resistance or voltage with a

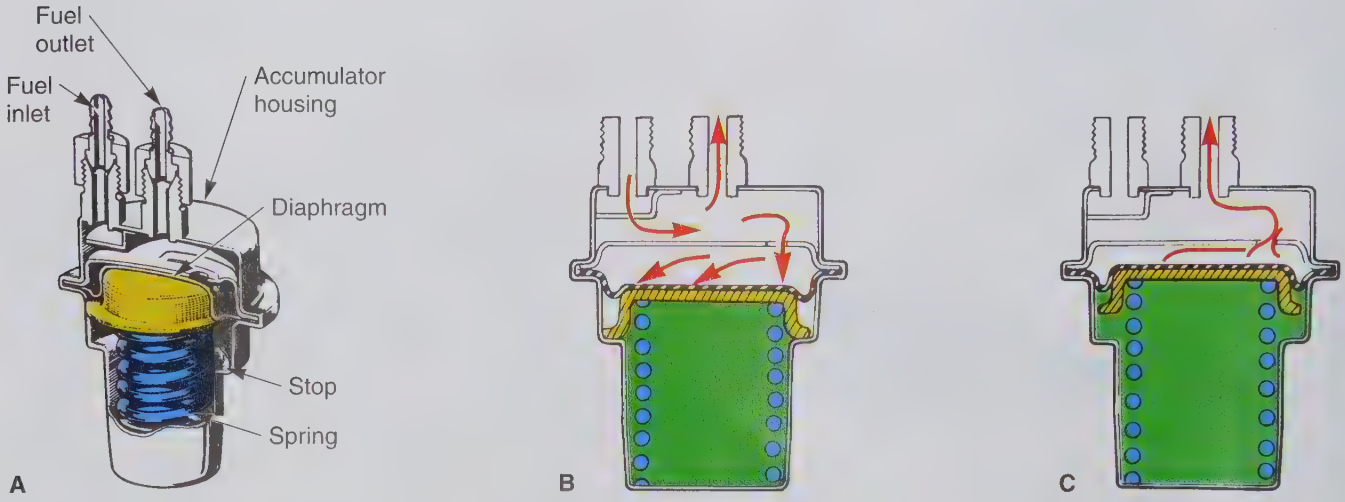

Figure 22-50. A fuel accumulator is simply a spring-loaded diaphragm. It dampens pressure pulsations in the system. It also maintains fuel pressure when the engine is shut off. C—When the engine is shut off, the spring pushes up on the diaphragm to hold pressure in the system. (Volvo)

change in a condition, such as temperature, pressure, or part position.

- The engine control module is the "brain" of the electronic fuel injection system.
- An oxygen sensor measures the oxygen content in the engine's exhaust system as a means of checking combustion efficiency.
- When in open loop, the electronic injection system does *not* use engine exhaust gas content as a main control of the air-fuel mixture.
- Closed loop means that the computer is using information from the oxygen sensor and other sensors.
- An idle air control motor may be used to help control engine idle speed.
- Unitized multiport injection is a system that mounts all of the fuel injectors in a single assembly.
- An injector resistor pack is a set of low-ohm resistors that control current flow to each injector coil.

Review Questions—Chapter 22

Please do not write in this text. Place your answers on a separate sheet of paper.

1. A gasoline injection system uses pressure from a(n) _____ _____ _____ to spray fuel into the engine _____ _____.
2. List seven possible advantages of a gasoline injection system over a carburetor system.
3. Explain the difference between throttle body and multiport injection systems.
4. Gasoline injection systems use _____ injection.
5. This is the most common and modern type of gasoline injection system.
   (A) Mechanical fuel injection.
   (B) Hydraulic fuel injection.
   (C) Electronic fuel injection.
   (D) Pneumatic fuel injection.
6. This type of gasoline injection pulses the injectors open and closed independently of the engine valve action.
   (A) Timed injection.
   (B) Intermittent injection.
   (C) Continuous injection.
   (D) Bank injection.

7. List the parts typically included in an EFI fuel delivery system.
8. How does an EFI injector open and close?
9. Explain the action of an EFI system throttle valve.
10. An engine _____ is an electrical device that changes circuit resistance or voltage with a change in a condition, such as temperature, pressure, or part position.
11. Define the term "EFI control module."
12. A(n) _____ _____, also called a(n) _____ _____ _____, measures the oxygen content in the engine's exhaust system as a means of checking _____ _____.
13. When the intake manifold absolute pressure sensor detects high pressure (low vacuum), the computer would know that a(n) _____ mixture is needed for load conditions.
14. A throttle position sensor is a(n) _____ _____ connected to the _____ _____ _____.
15. Which of these is *not* a typical EFI system sensor?
    (A) Exhaust back pressure sensor.
    (B) Throttle position sensor.
    (C) Engine coolant temperature sensor.
    (D) Intake air temperature sensor.
16. Explain the difference between sensor analog and digital signals.
17. When an EFI system is in _____ loop, the computer uses stored information to operate the system.
18. When an EFI system is in _____ loop, the computer uses engine sensor information to control the system.
19. Define the term "injector pulse width."
20. List and explain the six major parts of a TBI unit.
21. What are the main differences between the throttle body for multiport injection and throttle body injection?
22. An EFI multiport injector fits into the _____ or _____ in the _____ manifold.
23. List and explain the eight major parts of an EFI multiport injector.
24. Describe the mixture control unit in a hydraulic-mechanical CIS.
25. A(n) _____ fuel injector is a spring-loaded fuel valve that does *not* use an electric coil.

ASE-Type Questions

1. Gasoline injection systems feed fuel into an engine using:
    (A) suction.
    (B) vacuum.
    (C) pressure.
    (D) All of the above.
2. Gasoline injection systems have several advantages over carburetor-type fuel systems, including each of these *except:*
    (A) lower emissions.
    (B) uses direct injection.
    (C) improved atomization.
    (D) better fuel distribution.
3. In which fuel injection system is gasoline sprayed into the top center of an intake manifold?
    (A) Port.
    (B) Electronic.
    (C) Multiport.
    (D) Throttle body.
4. Which of the following is *not* a common method used to control the amount of gasoline injected into an engine?
    (A) Hydraulic controls.
    (B) Mechanical controls.
    (C) Electronic controls.
    (D) Thermal controls.
5. Which injection system squirts fuel into the engine right before or as the intake valves open?
    (A) Timed.
    (B) Modulated.
    (C) Continuous.
    (D) Intermittent.
6. The sensor used to detect engine speed is the:
    (A) throttle position sensor.
    (B) manifold pressure sensor.
    (C) crankshaft position sensor.
    (D) idle valve actuator.
7. Which of the following is *not* a throttle body injector part?
    (A) Bypass valve.
    (B) Injector spring.
    (C) Ball or needle valve.
    (D) Armature or plunger.

8. While discussing electronic injection systems, Technician A states that most multiport EFI uses two solenoid injectors for each engine cylinder. Technician B says such a system uses only one solenoid injector per engine cylinder. Who is right?
   (A) *A only.*
   (B) *B only.*
   (C) *Both A and B.*
   (D) *Neither A nor B.*
9. Which of the following is a flap-operated variable resistor?
   (A) *Venturi.*
   (B) *Fuel rail.*
   (C) *Airflow sensor.*
   (D) *Port fuel injector.*
10. Which of the following is used to help dampen pressure pulses and maintain fuel pressure when the system is shut off?
    (A) *Airflow sensor.*
    (B) *Pressure sensor.*
    (C) *Accumulator.*
    (D) *Cold start sensor.*

Activities—Chapter 22

1. Using a service manual for a fuel-injected vehicle, study the section on fuel injector operation. Demonstrate to your instructor your understanding of how the injectors are controlled.
2. Develop a drawing of the fuel injection system for a gasoline engine and produce an overhead transparency from it. Using the transparency or handouts, explain to the class how the system works.
3. Prepare simple sketches to show the basic difference between a carbureted fuel system and a throttle body injection fuel system.

23

Gasoline Injection Diagnosis and Repair

After studying this chapter, you will be able to:

- Diagnose typical gasoline injection system problems.
- Test a fuel pressure regulator.
- Test both electronic and continuous fuel injectors.
- Explain OBD II testing features used on late-model fuel injection systems.
- Use a service manual when making basic adjustments on gasoline injection systems.
- Cite safety rules for injection system service.
- Correctly answer ASE certification test questions about fuel injection system diagnosis, service, and repair.

As you have learned, several types of gasoline injection systems are used by automakers. Most types have similar parts (injectors, control module, and sensors). This chapter describes the most common gasoline injection system problems, tests, adjustments, and repair procedures. It also explains the service methods used on vehicles equipped with OBD II systems.

Gasoline Injection Problem Diagnosis

To diagnose problems in a gasoline injection system, you must use:

- Your knowledge of system operation.
- Basic troubleshooting skills.
- A service manual.
- A scan tool on late-model vehicles.

As you try to locate problems, visualize the operation of the four subsystems: air, fuel, sensor, control. Relate the function of each subsystem component to the problem. This will let you eliminate several possible problem sources and concentrate on others.

Verify the Problem

Before you test the fuel injection system, verify the problem or complaint. Make sure that the customer or service writer has accurately described the symptoms.

Never attempt to repair a gasoline injection system until you have checked all other possible problem sources. The ignition system, for example, normally causes more problems than the injection system.

Inspecting Injection System

A general inspection of the engine and related components will sometimes reveal gasoline injection system troubles. Look at **Figure 23-1.** Check the condition of all hoses, wires, and other injection system components. Look for fuel leaks, vacuum leaks, kinked lines, loose electrical connections, and other problems. Thoroughly check the components most likely to cause the particular symptoms. See **Figure 23-2.**

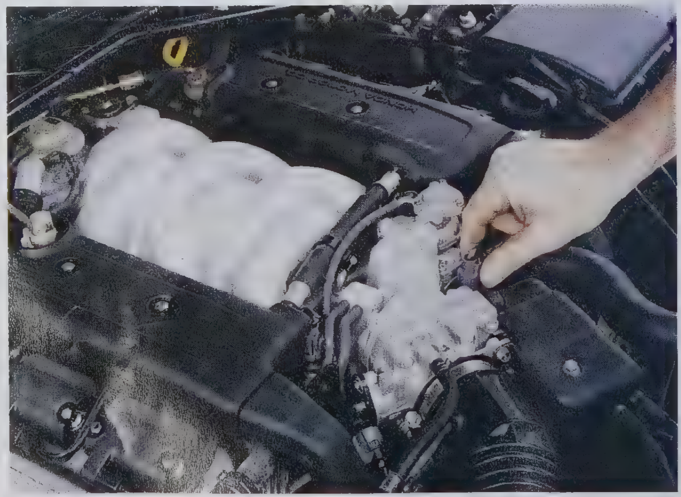

Figure 23-1. Close inspection of the engine compartment is important. Look for loose wires, leaking hoses, and other obvious troubles.

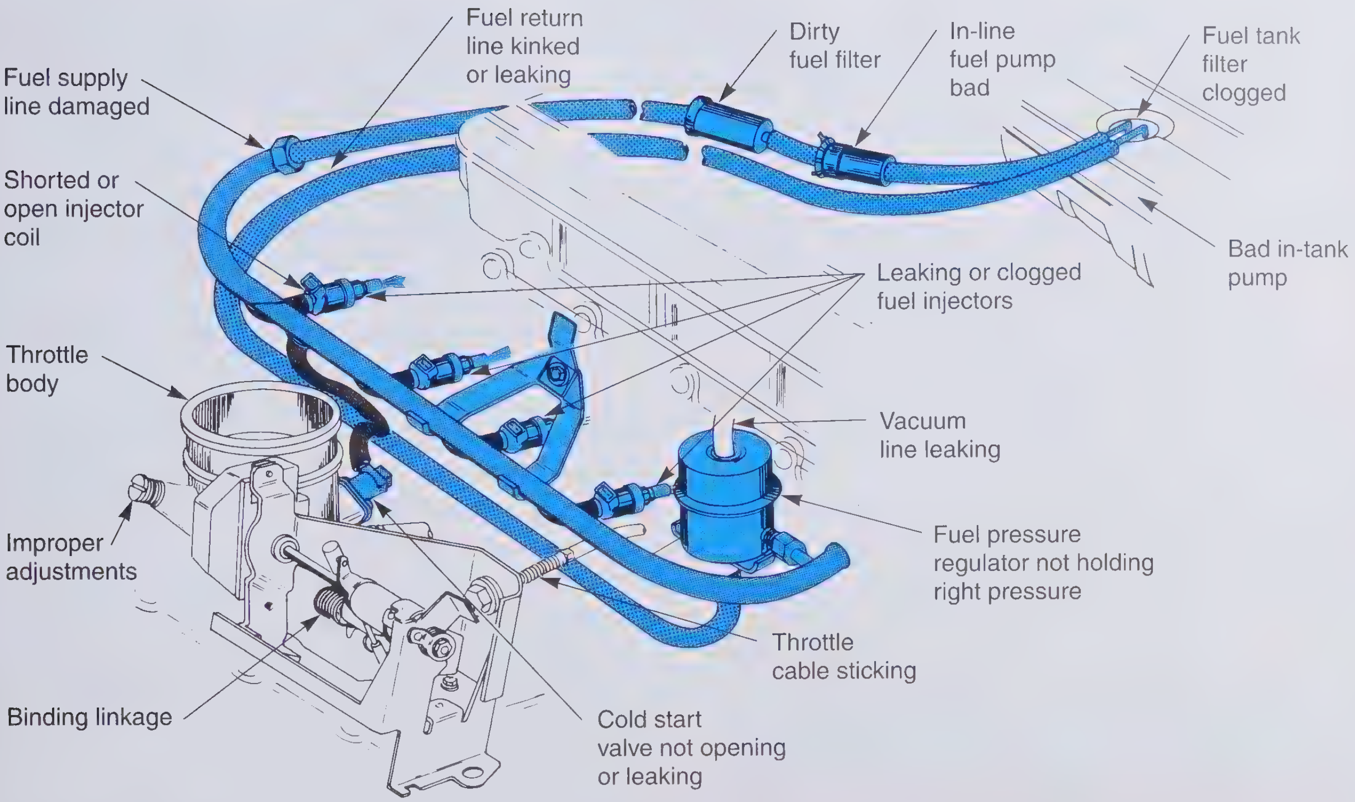
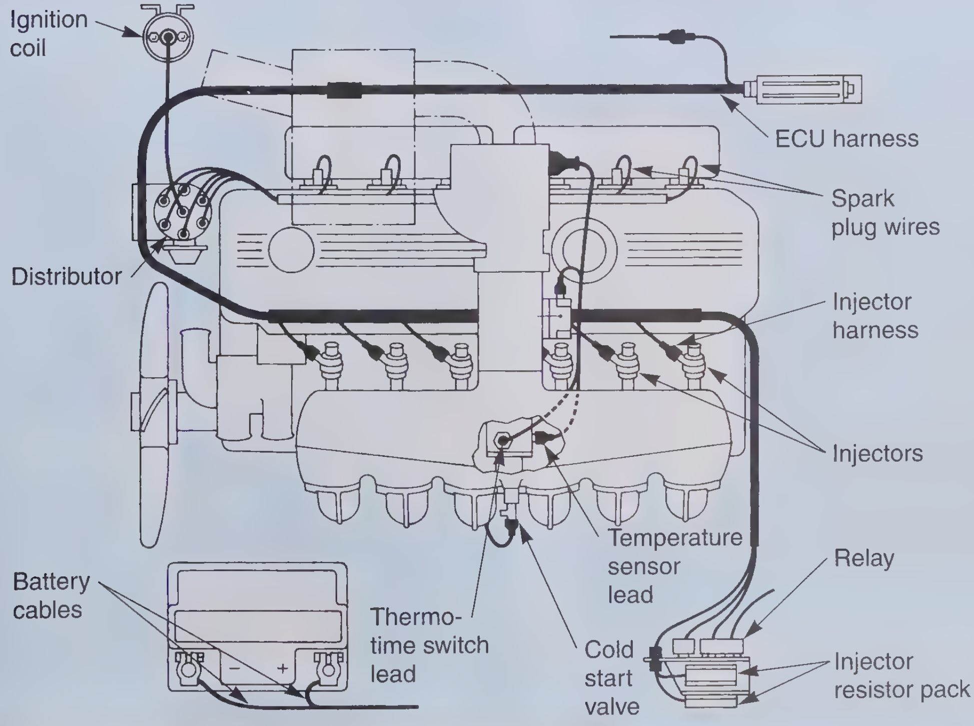


Fuel supply line damaged
Fuel return line kinked or leaking
Dirty fuel filter
In-line fuel pump bad
Fuel tank filter clogged
Shorted or open injector coil
Bad in-tank pump
Leaking or clogged fuel injectors
Throttle body
Vacuum line leaking
Fuel pressure regulator not holding right pressure
Improper adjustments
Throttle cable sticking
Binding linkage
Cold start valve not opening or leaking

Figure 23-2. After evaluating symptoms, try to narrow the list of components that could be at fault. Visualize the operation of each part and do not overlook common problems, such as a clogged fuel filter. (Fiat)



Ignition coil
ECU harness
Spark plug wires
Distributor
Injector harness
Injectors
Temperature sensor lead
Relay
Battery cables
Thermo-time switch lead
Cold start valve
Injector resistor pack

Figure 23-3. When diagnosing problems in EFI systems, check the electrical connections closely. One loose or disconnected wire could upset system operation.

With an EFI system, you may need to disconnect and check the terminals of the wiring harness. Look at **Figure 23-3.** Inspect the terminals for rust, corrosion, and burning. High resistance at the terminal connections is a frequent cause of problems.

Caution!

Do not disconnect an EFI harness terminal when the ignition switch is in the *on position.* This can damage the control module. Refer to a service manual for details. You may be instructed to disconnect the negative battery terminal during EFI service.

On-Board Diagnostics

Most EFI systems have on-board diagnostic abilities, which means the vehicle's computer can detect and record possible faults. The computer can detect a bad component and produce a ***trouble code*** pinpointing the problem. Specific systems vary depending on make, model, and year.

When a ***malfunction indicator light*** (MIL) in the dashboard glows, it tells the driver and the technician that something is wrong. The technician can then use service manual procedures to activate the self-diagnostic mode or to connect a scan tool to the system.

Some older diagnostic systems display the trouble codes as *numbers* in a digital display located on the dash panel. Other systems produce an *on-off* type code by flashing the check engine light. See **Figure 23-4.** In some systems, the diagnostic codes must be retrieved with an analog meter that is connected to a specified circuit test point. In all cases, the numbers have to be compared to a chart in the service manual to pinpoint the faulty circuit or component.

A ***scan tool*** will find and display many problems related to an electronic fuel injection system, **Figure 23-5.** It is connected to a data link connector on the vehicle.

B

Figure 23-4. Modern EFI systems have a self-diagnostic mode. When a trouble light flashes, the technician knows the system should be checked. After activating the self-diagnostic mode, some older systems display the number code in the dash. A—Dash number indicates trouble code. B—Partial list of trouble codes from one service manual. (Cadillac)

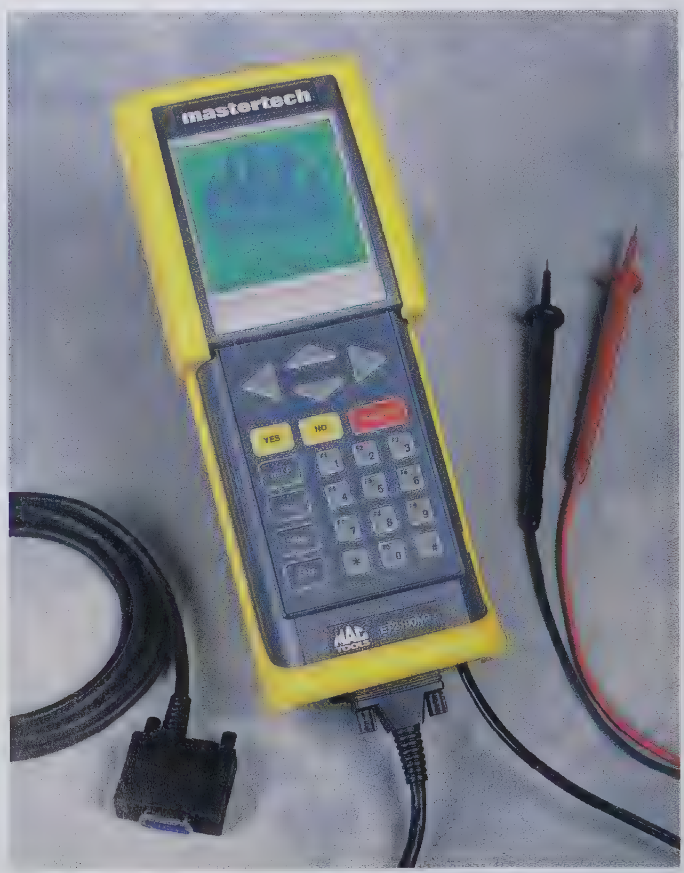

Figure 23-5. A scan tool can be used to find some problems in an electronic fuel injection system. It will detect lean or rich conditions, random misfiring, bad sensor circuits, inoperative actuators, etc. This particular scan tool is also equipped with a multimeter. (Mac Tools)

Always scan for trouble codes before attempting other diagnostic procedures. This may help you find the source of the problem more quickly. Modern scanners will automatically convert the trouble code number into an explanation of potential problems.

OBD II Fuel System Monitoring

With late-model on-board diagnostic (OBD II) systems, the vehicle's computer will record potential problems in its memory. The scanner can read this data and convert it into a brief description of the problem. The scanner will tell you which sensors, injectors, and other monitored components are not operating normally. The scan tool may also indicate what might be wrong with the component. This will save considerable time when troubleshooting.

Vehicles equipped with OBD II systems can set trouble codes that pinpoint injector problems. For example, if the scan tool readout shows a problem with the number three injector, you know to test this injector and its supply circuit for problems. The scan tool will also help you find common problems with system sensors and other actuators. You would then perform pinpoint tests to validate the scanner readout.

Note!
For more information on on-board diagnostics, refer to Chapter 18, *On-Board Diagnostics and Scan Tools.*

Fuel system monitoring involves checking whether a stoichiometric, or theoretically perfect, fuel mixture is being fed to the engine. Primarily, the feedback from the upstream oxygen sensor (located before catalytic converter) is used to determine fuel mixture content. If the oxygen sensor detects abnormal combustion resulting from a poor fuel mixture, it trips a trouble code.

Before a trouble code is tripped, however, the computer will try to adjust the fuel mixture as needed. It will alter the temporary fuel trim or injector pulse width to compensate for abnormal combustion by-products.

Short term fuel trim refers to the temporary adjustment of injector pulse width to correct the fuel mixture. ***Long term fuel trim*** is a permanent adjustment of injector pulse width to compensate for altered operating parameters. The computer uses this data to determine if the vehicle will pass an emissions test.

Minor fuel trim adjustments are normal with part wear. However, if the computer determines the vehicle might flunk an emission test from fuel trim data, it will trip a trouble code to warn the driver and technician.

OBD II Oxygen Sensor Monitoring

Oxygen sensor monitoring is done to keep the normally closed loop mode of operation efficient. The computer usually checks the upstream oxygen sensor for abnormal voltage, slow response times, and similar problems. It also checks the downstream oxygen sensor for normal voltage output. If abnormal voltages are detected, a trouble code is produced.

Note that many oxygen sensors in OBD II systems are heated to speed warm-up. Quicker oxygen sensor warm-up allows the computer system to go from open loop (startup or cold mode) to closed loop (full operating temperature mode) in less time. In closed loop, the computer can quickly make its own adjustments of fuel mixture based on feedback information from the sensors.

The oxygen sensor ***heater monitor*** checks the action of the heating element in the sensor. It does this by rapidly turning the heating element on and off while checking its response. If the control module detects an abnormal heater response, it trips a trouble code.

Note!
For more information on scanning fuel system–related problems, refer to the text index. Other chapters have relevant information.

EFI Testers

When the early EFI system does not have on-board diagnostics, an EFI tester can sometimes be used to locate system troubles. The tester, also called an EFI analyzer, is connected to the wiring harness of the system.

An ***EFI tester*** uses indicator lights and sometimes a digital meter (volt-ohmmeter-ammeter) to check system operation. The technician refers to the instructions with the tester and uses indicator light action to make various tests.

EFI testers are usually "make" specific. Each tester is designed to test only one make of vehicle. EFI testers are often used in large new car dealerships.

Oscilloscope Tests

An ***oscilloscope*** can sometimes be used to test or view the electrical waveforms (voltage values) at the EFI injector circuits. This provides a quick and easy way of diagnosing injector, wiring harness, and computer or control module problems.

Note!
For information on using oscilloscopes, see Chapter 46, *Advanced Diagnostics.*

Fuel Pressure Regulator Service

A faulty ***fuel pressure regulator*** can cause an extremely rich or lean mixture. If the output pressure is high, too much fuel will spray out of the injectors, causing a rich mixture. If the regulator bypasses too much fuel to the tank (low pressure), not enough fuel will spray out each injector. This causes a lean mixture.

Relieving EFI System Pressure

Warning!
Always relieve fuel pressure before disconnecting any EFI fuel line. Many gasoline injection systems maintain fuel pressure (as high as 60 psi or 414 kPa), even when the engine is *not* running. At this pressure, fuel could spray out with great force, causing eye injury or a fire!

Some EFI systems have a special ***relief valve*** for bleeding pressure back to the fuel tank. In other systems, the pressure regulator may allow pressure relief. Look at **Figure 23-6.**

When a relief valve or a pressure regulator relief is *not* provided, remove the fuse for the fuel pump or disconnect its wires. Start and idle the engine. When the engine stalls from lack of fuel, the pressure has been removed from the system. It is then safe to work.

Testing Fuel Pressure Regulator

Although exact procedures vary, you can test a fuel pressure regulator and fuel pump pressure with a pressure gauge, **Figure 23-7.**

Connect the gauge to the ***Schrader valve*** (fuel pressure test fitting) on the fuel rail. Start the engine and note the pressure gauge reading. If the reading is higher or lower than specs, the pressure regulator may be bad.

With low fuel pressure, check the fuel pump and fuel filters *before* replacing the regulator. A bad electric fuel pump or partially clogged filter could be lowering fuel pressure. High pressure is commonly due to a bad pressure regulator.

To test maximum fuel pump pressure, place a rag over the fuel return hose. Use pliers to squeeze and block the hose. This will prevent fuel pressure regulator fuel return. The pressure gauge reading should then increase to maximum fuel pump pressure. If fuel pressure remains too low with the return line blocked, the fuel pump, not the pressure regulator, is at fault. See **Figure 23-8.**

Fuel Pressure Regulator Replacement

With throttle body injection, the fuel pressure regulator is normally located on the throttle body assembly. With multiport injection, the pressure regulator is normally located on a branch connected to the fuel rail (manifold) or injectors. Look at **Figure 23-9.** Replace the

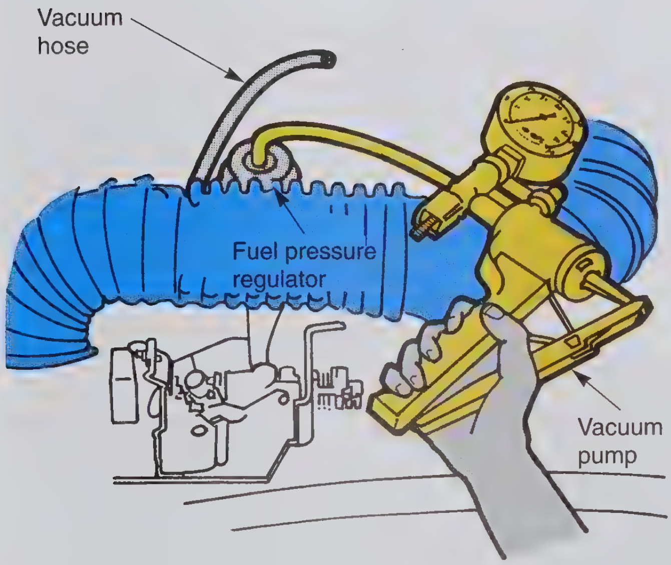

Figure 23-6. Bleed off system pressure before working on the system. When a vacuum-operated pressure regulator is used, applying vacuum to the regulator will relieve the fuel pressure. Fuel flows back to the fuel tank. (Fiat)

Figure 23-7. To check the pressure regulator, fuel pump, and filters, connect the pressure gauge before the injectors. Pressure should be within specs. If not, check the filters and pump before replacing the regulator. (Ford)

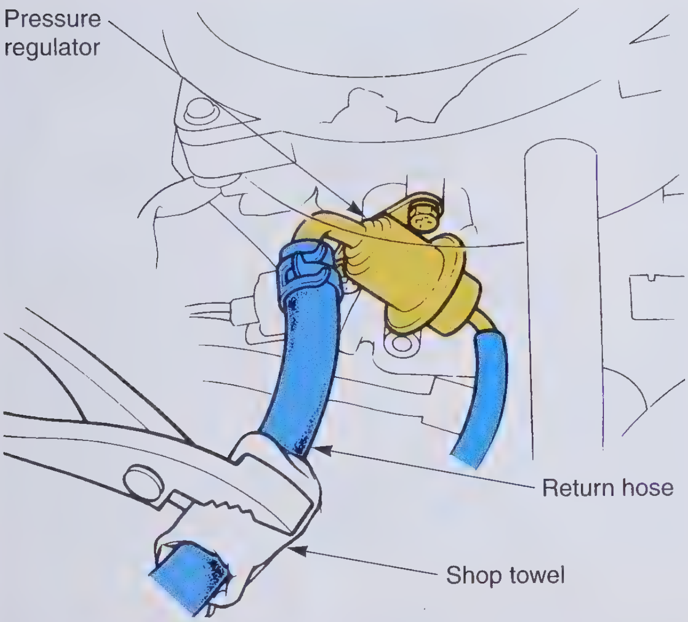

Figure 23-8. If fuel pressure is low, pinch the fuel return hose. This will isolate the trouble to either the fuel pump or the pressure regulator. If pressure increases to above normal with the hose pinched, the regulator is probably bad. (Honda)

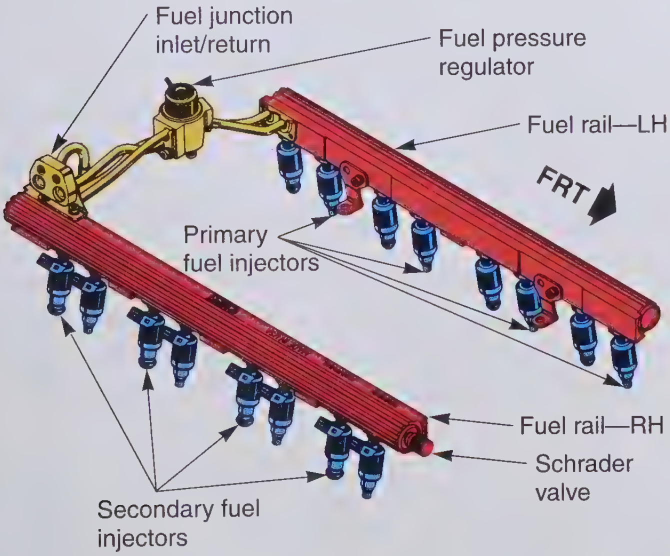

Figure 23-9. Note the location of the pressure regulator and service valve on this multiport injection fuel rail assembly. (Chevrolet)

fuel pressure regulator according to service manual directions. Use new seals or gaskets between the regulator and rail.

Injector Problems

A ***bad injector*** can cause a wide range of problems including rough idle, hard starting, poor fuel economy, and engine miss. It is very important that each fuel injector provide the correct fuel spray pattern.

A ***leaking injector*** richens the fuel mixture by allowing extra fuel to drip from the closed injector valve. The injector valve may be worn or dirty, or the return spring may be weak or broken.

A ***dirty injector*** can restrict fuel flow and make the mixture too lean. If foreign matter collects in the valve, a poor spray pattern and inadequate fuel delivery can result.

An ***inoperative EFI injector*** normally has shorted or open coil windings. Current is reaching the injector, but since the coil is bad, a magnetic field cannot form and open the injector valve.

A continuous injector that does not use a solenoid will usually operate, but may have a poor spray pattern or weak spring (incorrect opening pressure).

Throttle Body Injector Service

You can quickly check the operation of a throttle body injection system by watching the fuel spray pattern in the throttle body. Remove the air cleaner. With the engine cranking (no-start problem) or running, each injector should form a rapidly pulsing spray of fuel.

Testing TBI injectors

If fuel system pressure is within specifications but the TBI injector does not spray fuel, follow service manual procedures to test for power to the injector solenoid. **Figure 23-10** illustrates some simple tests recommended by one automaker.

No power (current) to the injector would indicate a problem with the wiring harness or electronic control module.

If you have power but no fuel spray pattern, the injector may be bad. Make sure you have adequate fuel pressure before condemning a fuel injector.

Replacing TBI Injectors

Although exact procedures vary with throttle body design, there are a few rules to follow when replacing a TBI injector. These rules include:

- Relieve system fuel pressure before removing any throttle body component.
- Disconnect the negative battery cable.
- Label all hoses and wires before removal, **Figure 23-11.**
- Do not damage the throttle body housing when pulling or prying out the injector, **Figure 23-12.**

An ohmmeter can be used at the other end of the harness. (Ford)

- Install new rubber O-rings. You may need to lubricate the O-ring with approved lubricant to aid new injector installation.
- Double-check that you have installed all injector washers and O-rings correctly.
- Push the injector into the throttle body by hand. Avoid using a hammer or pliers. You may damage the new injector. Look at **Figure 23-11.**

Figure 23-11. When removing the throttle body, label wires and hoses. Unscrew the four fasteners and lift off unit. When installing, double-check the connection of wires and hoses. Torque the fasteners properly using a crisscross pattern.

- Make sure the injector is fully seated in the throttle body. Normally, a tab must fit into a notch, ensuring correct alignment.
- Check for fuel leaks after TBI injector installation. Test drive the car.

Throttle Body Rebuild

A ***throttle body rebuild***, like a carburetor rebuild, involves replacing all gaskets, seals, and other worn parts. You must remove and disassemble the throttle body, making sure all plastic, rubber, and electrical parts are removed.

The metal parts are soaked in carburetor cleaner, washed in cold soak cleaner, and blown dry.

Warning!
Carburetor cleaner is a very powerful solvent. Wear eye protection and rubber gloves when working this type of cleaner. Follow the directions on the solvent label in case of an accident.

Inspect each part carefully for signs of wear or damage. Then, reassemble the TBI unit following the instructions in a manual.

Install the throttle body on the engine as you would a carburetor. Use a new base plate gasket. Tighten the hold-down fasteners equally and to the proper torque. Make sure all vacuum hoses are connected to the correct vacuum port on the throttle body. Start the engine. Check for leaks and smooth system operation.

C—If needed, use new O-rings and washers. D—Carefully align and push the injector into the throttle body with your thumbs. (General Motors)

Note!
Chapter 22, *Gasoline Injection Fundamentals,* covers subjects related to rebuilding a throttle body assembly.

Tech Tip!
Icing or freeze up can occur in the throttle body of fuel injection systems. This can happen when the thermostatic flap in the air inlet system sticks in the open position. Only cool outside air, not engine preheated warm air, is flowing through the throttle body. Throttle body icing can occur even when the outside temperature is well above freezing.

Servicing EFI Multiport Injectors

The service of an injector for a multiport EFI system is like the service procedures for a TBI system. However, multiport injectors are located in the intake manifold runners instead of in the throttle body assembly.

Testing EFI Multiport Injector Operation

To quickly make sure each EFI injector is opening and closing, place a ***stethoscope*** (listening device) against each injector, **Figure 23-13.** A clicking sound means the injector is opening and closing. If you do *not* hear a clicking sound, the injector is not working. The injector solenoid, wiring harness, or control module control circuit may be bad.

With the engine off, you can check the condition of the coils on the inoperative injector. Use an ohmmeter. Measure the resistance across the injector coil. If the coil is open (infinite resistance) or shorted (zero resistance to ground), you must replace the injector.

An injector coil tester is available for more accurately testing the electrical condition of the fuel injectors. Its use is demonstrated in **Figure 23-14.**

If the injector tests good, you may need to check the wiring going to that injector. Following the service manual, check supply voltage to the inoperative injector. You may also need to measure the resistance in the

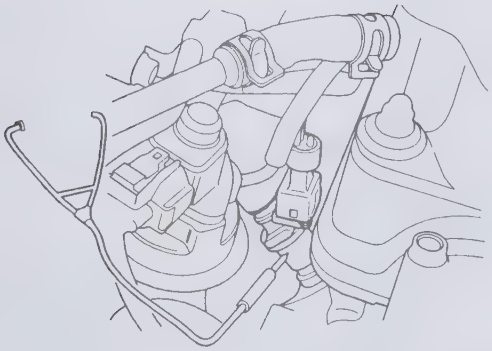

Figure 23-13. If the engine is missing and you suspect an injector, place a stethoscope on the side of the injector. A clicking sound shows that power is reaching the injector and the injector is opening and closing. (Honda)

Figure 23-14. This injector tester checks the injector coil for problems. It is faster and more accurate to use than a voltmeter or an ohmmeter alone, because it sends normal current through the injector. Since injector coil resistance and current flow drops as the injector warms, use the lowest reading obtained during the test. If the reading jumps up and down, suspect a partially open winding in the coil. A—Connections for using a fuel injector coil tester and digital multimeter. B—Compare readings from all injectors to determine if any are bad. Note that injector No. 5 is low and should be replaced. (Chevrolet)

circuit between the injector solenoid and the control module. A high resistance would indicate a frayed wire, broken wire, or poor electrical connection.

Injector Noid Light Test

A ***noid light*** is a special test light for checking electronic fuel injector feed circuits, **Figure 23-15.** Different noid lights are made to fit wiring harnesses from each auto manufacturer. Usually the makes of vehicles the noid light will fit are printed on the tool.

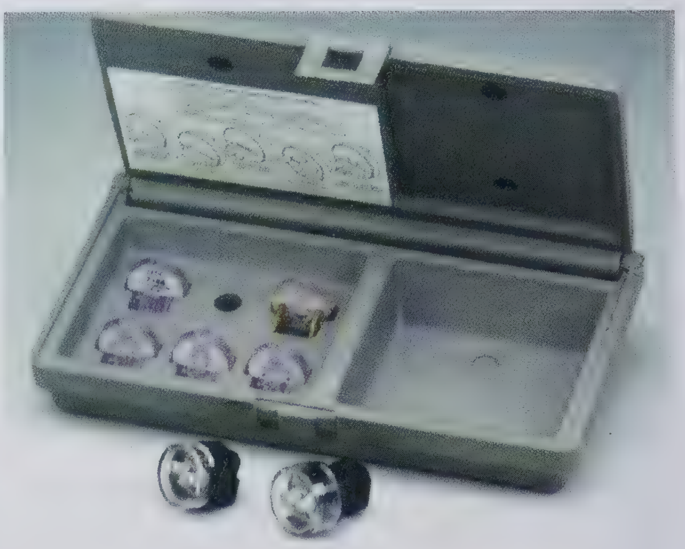

Figure 23-15. Noid lights are designed to check for normal current pulse being sent to each injector. Correct noid light must be used to prevent wiring connector damage. (OTC)

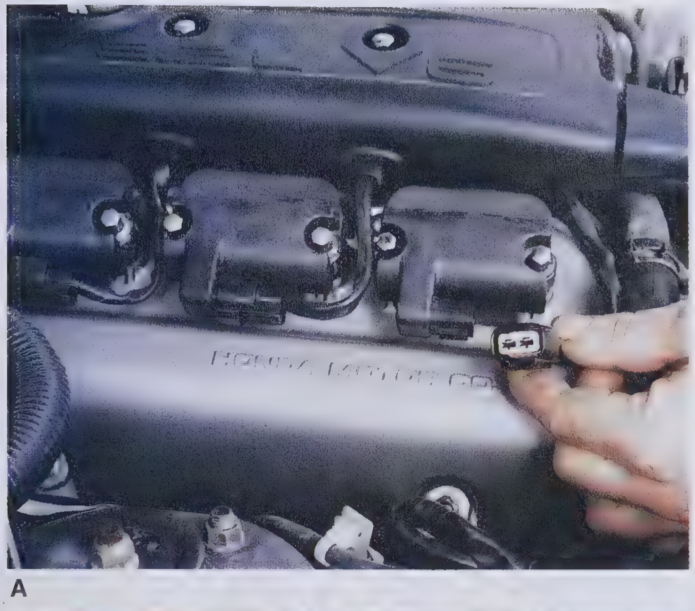
To use a noid light:

1. Disconnect the wiring harness from the fuel injector, **Figure 23-16A.** Make sure you release the connector properly to prevent part damage. Most harness connectors use a positive lock to keep the wiring from vibrating loose.
2. Fit the correct style noid light into the injector harness connector, **Figure 23-16B.**
3. Start the engine and check the light.
4. If the noid light flashes, you know that power is reaching the injector from the control module or control unit. If the noid light does *not* flash on and off, something is keeping current from reaching the noid light and injector. You could have an open in the wiring, a bad connection, open injector resistors, or control module troubles.



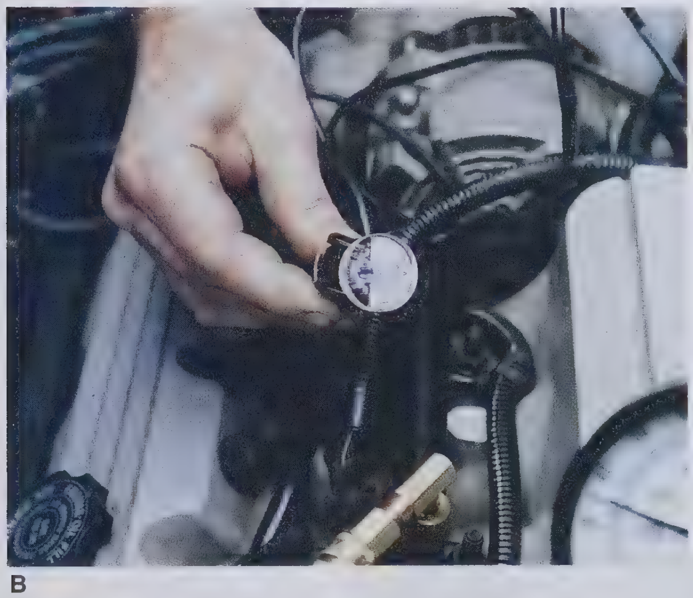


Figure 23-16. A—To use a noid test light, disconnect the harness from the injector. To avoid damage, release the locking mechanism on the connector. Do not force it off. B—Install the noid light into the injector connector. Start the engine. The noid light should flash on and off, showing electrical pulses for the injector. If not, check the wiring, connections, and control unit.

5. Repeat the noid light test on any injector that is not operating. Your stethoscope will quickly tell you which injector is "dead" and not clicking.

Refer to a wiring diagram when solving complex fuel injection electrical problems. The diagram will show all electrical connections and components that can upset the function of the injection system.

Caution!
Some EFI multiport systems use dropping resistors before the injectors. The resistors lower the supply voltage to the injectors. Do *not* connect direct battery voltage to this type of injector, or coil damage may occur.

Injector balance test

An ***injector balance test*** uses a fuel injector tester to measure the amount of fuel flowing through each injector. This is a common test performed on modern multiport, electronic fuel injection systems. It will tell you if any injectors are clogged or not opening fully.

An electronic fuel injector tester is a tool that will fire an injector for a specific amount of time. Instead of the vehicles' computer, the tool feeds current to the injector coil to make it open for a controlled time span. One is shown in **Figure 23-17.**

To perform an injector balance test:

1. Connect a pressure gauge to the test fitting on the fuel rail. Make sure all fittings are tight and not leaking.
2. Close off the valve for measuring fuel volume if provided on the fuel gauge assembly.

Figure 23-17. This is an injector flow balance tester. It can find clogged or partially failed fuel injectors. (OTC)

3. Connect the balance tester wiring to the injector in question and to the battery.
4. Turn the ignition key on to pressurize the system. Then, turn the ignition key off.
5. Press the injector balance tester button while watching the pressure gauge drop. See **Figure 23-18.**
6. Record your pressure drop reading.
7. Repeat this on the other fuel injectors. This will allow you to measure how much fuel each injector is feeding into the engine when energized.

If one of the injector shows a relatively low pressure drop, it is not injecting as much fuel as the others. That injector could be clogged or worn. If an injector shows a higher-than-normal pressure drop, it could be sticking open or not closing properly. Refer to **Figure 23-19.**

Replacing EFI Multiport Injectors

An EFI multiport injector is easy to replace. After bleeding off fuel pressure, simply remove the hose from the injector and fuel rail, **Figure 23-20.** Unplug the electrical connection and remove any fasteners holding the injector. Pull the injector out of the engine.

Sometimes, you must remove the fuel rail before you can service the injectors. All the injectors may have to be removed with the fuel rail. Then, each injector can be removed from the rail.

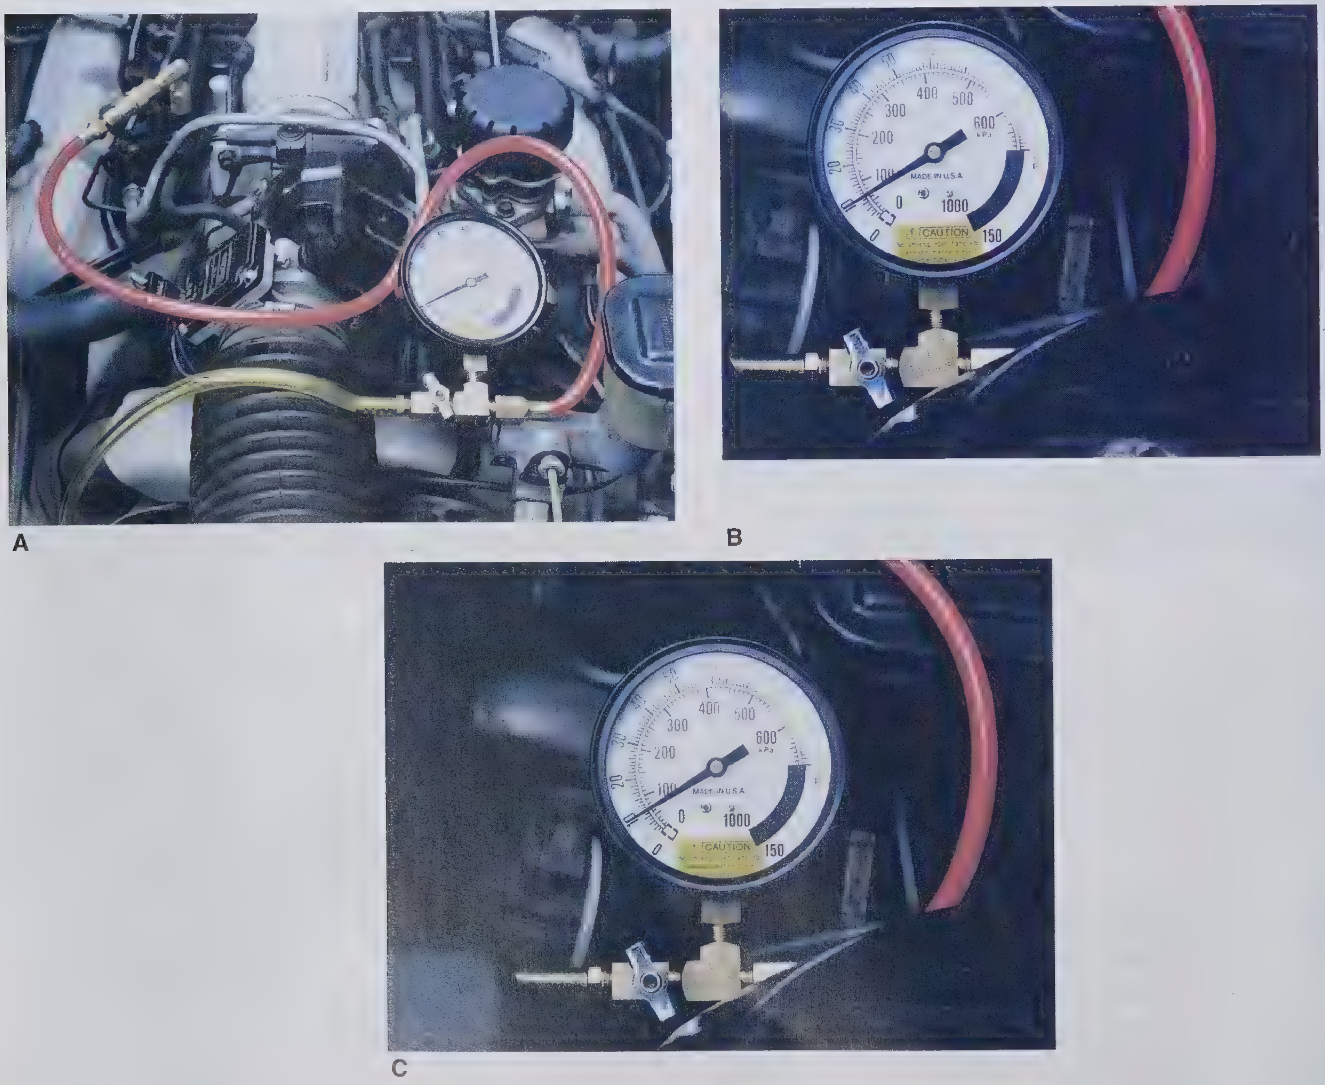

Figure 23-18. An injector flow balance test will find clogged or failing fuel injectors. A—Connect a pressure gauge to the fuel rail test fitting. If necessary, close the gauge valve for measuring fuel volume. B—Connect the injector balance tester to the injector terminals. Pressurize the system by turning the ignition key on or starting the engine. Then, shut the engine off. C—Press the button on the tester to fire the injector. Note the pressure drop after the injector has been fired. Compare all injector readings to determine if any are bad.

Faulty (more)
C

Retest injectors that appear faulty. Replace any injectors that have a 10 kPa difference (either more or less) in pressure drop.

Figure 23-19. Basic steps for doing a balance test on multiport injectors. A—Disconnect all wires from the injectors. Do not damage plastic connectors during removal. B—Connect the test harness to an injector and connect the pressure gauge to the test fitting on the fuel rail. Tester normally connects to the battery. Press tester button and note the pressure gauge reading. C—Pressure drop at the gauge should be the same for each injector. Turn the key on or activate the fuel pump between each test so the pressure is the same at each injector. If one injector has less pressure drop when fired, it might be clogged. If pressure drop is excessive, the injector might be worn or sticking. If pressure does not hold, the injector is leaking. (Chevrolet)

A ***fuel injector boot*** is a soft rubber grommet or O-ring that fits between the fuel injector and its opening in the engine. It must seal the opening to prevent engine vacuum leakage.

Inspect the boot and other rubber parts closely. Some manufacturers suggest that you replace the boot, seals, and hose if the injector is removed for service. Refer to **Figure 23-21.**

Install the new or serviced injector in reverse order, **Figure 23-22.** Use the directions in the shop manual for details. Exact procedures can vary.

Electronic Fuel Injector Cleaning

If the EFI injectors fail the balance test and show a low drop, they may be clogged and in need of cleaning, **Figure 23-23.**

A ***fuel injector cleaning tool*** uses shop air pressure to force a cleaning solution through the injectors to remove deposits. As shown in **Figure 23-24,** connect the tool to the fuel rail. Following tool instructions, force the cleaning agent through the injectors. If engine performance improves, the injectors have been successfully

cleaned. The cleaning agent is combustible and will burn as the engine operates.

Warning!
Make sure a shop exhaust hose is connected to the tailpipe when cleaning injectors. Exhaust fumes that occur during cleaning can be more toxic than normal.

Engine Sensor Service

Most EFI engine sensors can be checked with a scan tool. A modern scan tool will give operating values, which can be compared to specs. However, an engine sensor can also be checked with a digital meter or a test light if the vehicle is not equipped with advanced on-board diagnostics.

Caution!
When a service manual directs you to measure voltage or resistance in an EFI sensor, use a high-impedance meter or a digital meter. An inexpensive analog meter can damage some sensors.

Throttle Position Sensor Service

A throttle position sensor should produce a given amount of resistance for different throttle openings. For example, the sensor might have high resistance with the throttle plates closed and a lower resistance when the throttles are open. Compare your ohmmeter readings to specs to determine the condition of a throttle position sensor.

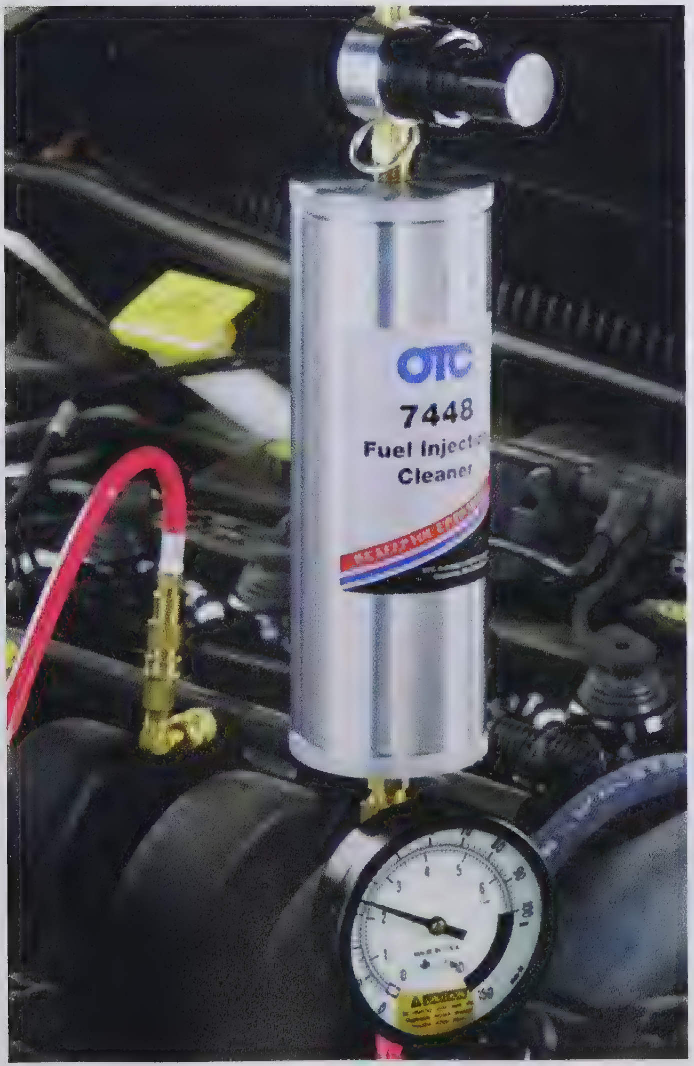

Figure 23-24. Fuel injector cleaner will force solvent through clogged or restricted injectors. Sometimes, this will return them to normal operation without removal. (OTC)

Throttle Position Sensor Service

A ***bad throttle position sensor*** (TPS) can affect fuel metering, ignition timing, and other control module outputs. It can also trip several trouble codes on some systems and can be a frequent cause of problems. Many throttle position sensors use contact points or variable resistors that can wear and fail.

A throttle position sensor signals the control module when the gas pedal is depressed to different positions for acceleration, deceleration, idle, cruise, and full power. It can cause a wide range of performance problems. If shorted, it might make the fuel mixture too rich or, if open, too lean.

The throttle position sensor can sometimes be tested at a special tester terminal in the wiring harness. Some manuals say you should measure voltage drops across the sensor at specified throttle positions. A reference voltage is fed to the sensor by the control module.

Many manuals also recommend checking the resistance of the throttle position sensor at different throttle openings. The manual might have you measure ohms at idle, half throttle, and full throttle. If resistance is within specs, check the wiring leading to the TPS.

Throttle Position Sensor Removal

To remove many throttle position sensors, you must file or grind off stakes (small welds) on the sensor screws. You might also have to drill into the screws from the bottom of the throttle body assembly. This will let you turn and remove the screws and TPS. Refer to the service manual for details.

Throttle Position Sensor Adjustment

Some throttle position sensors must be adjusted; others cannot be adjusted. Many are mounted so they can be rotated on the throttle body. Either a special tester or an ohmmeter is commonly used to adjust a throttle position sensor.

Basically, you must measure sensor resistance or note tester output with the throttle at specific positions. You may have to insert a feeler gauge under the throttle lever or have the throttle plates at curb idle, for example. With the throttle plates at the correct angle, the TPS should trigger the tester or show a specified ohms value. If an adjustment is needed and possible, loosen the sensor mounting screws. Rotate the TPS until the correct ohms reading is obtained. Then, tighten the mounting screws and recheck the adjustment.

Manifold Absolute Pressure Sensor Service

A ***bad manifold pressure sensor*** can affect the air-fuel ratio when the engine accelerates and decelerates. It senses changes in engine vacuum caused by changes in engine load or speed. Its signal is used by the ECM to determine the proper air-fuel mixture. It might also have some effect on ignition timing and a few other control module outputs.

To test a manifold pressure sensor, use your scan tool or measure sensor circuit voltage or sensor resistance while applying vacuum to the unit. Use a vacuum pump on the vacuum fitting of the sensor. Apply specified vacuum levels while measuring the output of the MAP sensor.

Some manuals instruct you to measure sensor voltage at a specified test terminal. Others might have you disconnect the wires from the sensor and compare ohmmeter readings to specs. In any case, sensor values must be within limits at the various vacuum levels. If testing at the test terminal, check the wiring harness before condemning the sensor. A poor connection or short could upset a reference voltage flowing to the sensor.

Oxygen Sensor Service

A ***bad oxygen sensor*** will primarily upset the fuel injection system or the computerized carburetor system. The voltage signal from the sensor represents air-fuel ratio. If the oxygen sensor produces a false output (incorrect voltage), the control module cannot precisely control how much fuel is metered into the engine. A rich mixture or lean misfire condition could result.

Tech Tip!
Oxygen sensors should be replaced at periodic intervals. After prolonged service, they become coated or fouled with exhaust by-products. As this happens, fuel economy and emissions will be adversely affected. If gas mileage is 10% to 15% lower than normal, suspect the oxygen sensor of slow response. One- and two-wire sensors should be replaced at about 50,000–60,000 miles (80,000–96,000 km). Heated three-wire oxygen sensors should be replaced at about 100,000 miles (160,000 km).

Oxygen Sensor Contamination

Depending on the type, an oxygen sensor can be expected to last from 50,000–100,000 miles. However, its life can be shortened by contamination, blocked outside air, shorts, and poor electrical connections.

Oxygen sensor contamination can be caused by:

- ***Leaded fuel.*** Leaded racing fuel or aftermarket performance products containing lead can cause oxygen sensor contamination. Lead coats the ceramic element and the sensor cannot produce enough voltage output for control module.

- ***Silicone.*** Sources are antifreeze, RTV silicone sealers, waterproofing sprays, and gasoline additives. Silicone forms a glassy coating.
- ***Carbon.*** Carbon contamination results from rich fuel mixtures. Carbon in fuel coats the sensor.

Carbon and moderate lead contamination can sometimes be reversed. Run the engine at high speeds with a large vacuum hose (PCV hose, for example) removed. This will sometimes burn off light lead and most carbon deposits. The sensor may start working normally again.

Oxygen Sensor Inspection

Also, check that the outside of the sensor and its electrical connection are free of oil, dirt, undercoating, and other deposits. If outside air cannot circulate through the oxygen sensor, the sensor will not function.

An oxygen sensor generates only a tiny voltage (an average of about 0.5 volts). A poor electrical connection can prevent this small voltage from reaching the control module. Always check the sensor's electrical connections.

Oxygen Sensor Testing

Discussed earlier, most on-board diagnostic systems will produce a trouble code and give operating voltages indicating when the output from the oxygen sensor is *not* within normal parameters. This would tell you to do further tests on the oxygen sensor and its circuit.

Many systems have a limp-in mode. If the oxygen sensor or some other sensor fails and produces an incorrect output, the system will go into this emergency limp-in mode. A predetermined oxygen sensor voltage (0.5 volts for example) will be simulated by the control module and used to keep the engine running well enough to drive in for repairs.

A digital voltmeter can also be used to test the output of an oxygen sensor. Warm the engine to full operating temperature to shift the system into closed loop. The sensor must be hot (about 600°F or 315°C) to operate properly. You may have to warm the engine at fast idle for up to 15 minutes with some cars. Note that a few systems can drop out of closed loop at idle.

Caution!
Only use a high-impedance digital meter to measure oxygen sensor voltage. A conventional analog or low-resistance meter can draw too much current and damage the oxygen sensor.

Oxygen Sensor Output Voltage

In most cases, ***oxygen sensor output voltage*** should cycle up and down from about 0.2–0.8 volts (200–800 mV). A 0.2 volt or low reading would show a lean air-fuel ratio and a 0.8 volt or high reading would show a richer condition. A high or low reading does not always mean the oxygen sensor is bad. Another problem (leaking or clogged fuel injector, for example) could make the sensor read high or low.

A quick test to see if the oxygen sensor reacts to a change in air-fuel mixture is to pull off a large vacuum hose, like the hose to the PCV valve. This extra air should make the oxygen sensor try to richen the fuel mixture and compensate for the air leak (lean condition). The output voltage will normally go *down* (to about 0.2 or 0.3 volts), to signal a need for more fuel to adjust for the vacuum leak or extra air.

When the engine throttle is snapped open and closed, oxygen sensor output should also cycle up and down to show the change in air-fuel mixture.

If you block the air inlet at the air cleaner or inject propane gas into the air inlet (creating a rich mixture), the oxygen sensor voltage should *increase* (go up to about 0.8 to 0.9 volts). The sensor should try to signal the computer that too much fuel, or not enough air, is entering the combustion chambers.

If the oxygen sensor is lazy or its voltage does not change properly as you simulate rich and lean air-fuel ratios, the oxygen sensor is faulty. You might try running the engine at high speed, with a large vacuum hose removed, to clean off light carbon contamination.

A faulty oxygen sensor will usually be locked at one voltage level and will not cycle voltage up and down. It also may not produce enough voltage.

Testing Oxygen Sensor Circuit

If the oxygen sensor has normal voltage, you should check the circuit leading to the sensor. Measure the resistance of the wires leading to the oxygen sensor. You can use long test leads. You can also ground one end of the sensor wire and check it for continuity at the other end.

Oxygen Sensor Replacement

Disconnect the negative battery cable. Then, separate the sensor from the wiring harness by unplugging the connector. Never pull on the wires themselves, as damage may result.

The oxygen sensor may have a permanently attached pigtail. Never attempt to remove it. Use a wrench to unscrew the sensor. Inspect its condition. Some sensors may be difficult to remove at temperatures below 120°F. Use care to avoid thread damage.

Tech Tip!
When attempting to remove an oxygen sensor with seized threads, you can unintentionally round off the hex nut with a slotted sensor socket. If this happens, cut off the sensor wires

and use a six-point deep-well or spark plug socket. If the sensor's hex nut is not badly damaged, the socket should grasp and turn the "stubborn" oxygen sensor.

Coat the threads of the new sensor with anti-seize compound. Start the sensor by hand. Then tighten it with a wrench. Do not overtighten the sensor, or it may be damaged. Check fuel injection system operation after sensor installation.

Remember the following rules when installing an oxygen sensor:

- Do not touch the sensor element with anything (water, solvents, etc.).
- Do not use silicone-based sealers on or around the exhaust system components. To prevent oxygen sensor contamination, use only "low-volatile" silicone sealers on engine components Be sure to use these sealers sparingly. The PCV system can draw silicone fumes into the engine intake manifold and over the sensitive, easy-to-contaminate oxygen sensor.
- Before sensor replacement, repair any engine oil or coolant leaks that might contaminate the new oxygen sensor.
- Hand start the sensor to prevent cross threading.
- Do not overtighten the oxygen sensor. Overtightening can cause damage.
- Make sure the outside vents are clear so air can circulate through the sensor.
- Make sure wiring is reconnected securely to the sensor.
- Check oxygen sensor output and fuel system operation after installing sensor.

Reading Oxygen Sensor

Reading an oxygen sensor can indicate fuel system problems, silicone contamination, and other troubles. To ***read an oxygen sensor***, inspect the color of the sensor's tip. See **Figure 23-25.**

- A *light gray tip* is normal for an oxygen sensor.
- A *white sensor tip* might indicate a lean mixture or silicone contamination. Sensor must usually be replaced.
- A *tan sensor tip* could be lead contamination. It can sometimes be cleaned away, but a new sensor is usually needed.
- A *black sensor tip* normally indicates a rich mixture and carbon contamination, which can sometimes be cleaned after correcting the cause.

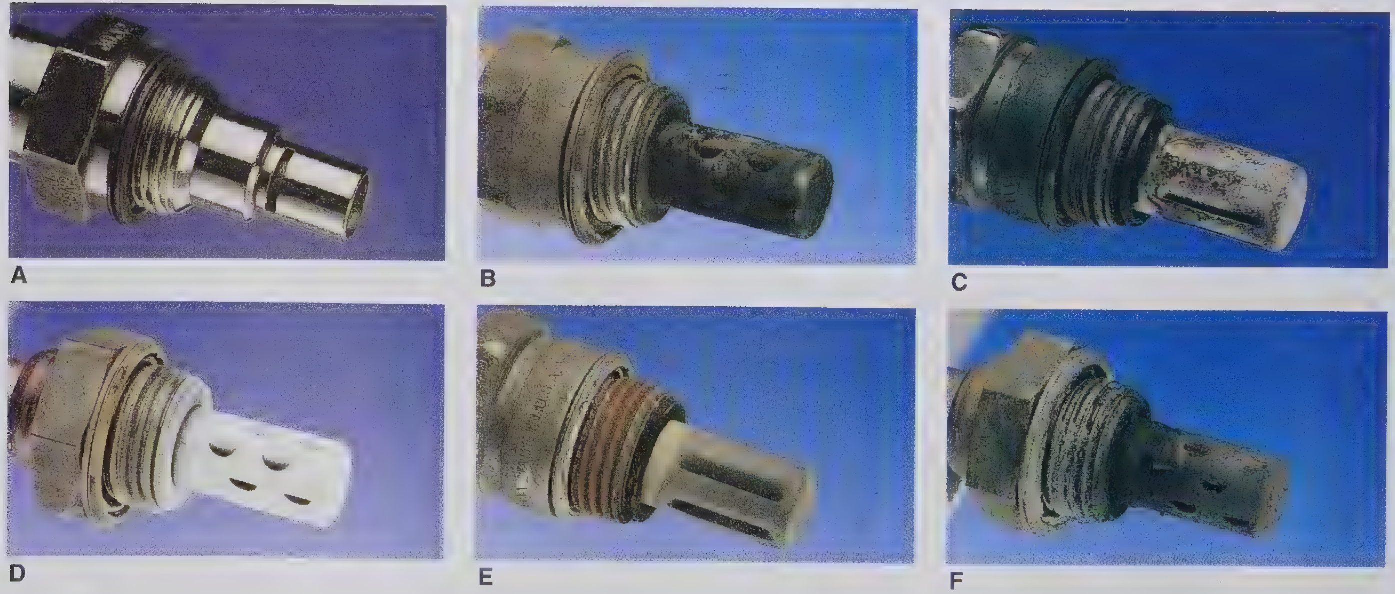

Figure 23-25. After removing an oxygen sensor, note the color of its tip. This can give you information about the condition of the engine and its support systems. A—The new oxygen sensor must be identical to and have the same part number as the old one. This is a high-quality platinum oxygen sensor that is designed to provide long service life. B—A rich mixture caused by a fuel system problem has coated this sensor with black soot. C—Antifreeze contamination was caused by a leaking head gasket or a crack in the engine. D—Silicone contamination resulted from the use of too much silicone sealer during an engine rebuild. E—Lead contamination was caused by using leaded racing fuel or a lead octane additive. Check the fuel tank filler neck for modification. F—Oil contamination caused by worn piston rings and valve seals. (Tomco Inc.)

Note that some manufacturers recommend oxygen sensor replacement after only 12,000 miles (19,308 km) when the sensor is removed. Therefore, the oxygen sensor is normally replaced with a new one when unscrewed from the exhaust system.

Oxygen Sensor Signal Generator

An ***oxygen sensor signal generator*** is a tool for sending a false 200–800 mV signal to the control module for testing purposes. You can then alter air-fuel ratio (simulate vacuum leak for example) and perform other testing functions. Since the control module thinks it is closed loop, you can do tests without the control module tripping a trouble code or trying to compensate for your intentional modifications of engine operating conditions.

Temperature Sensor Service

Most EFI systems use both an engine coolant temperature sensor and an intake air temperature sensor. If these sensors are bad, they will make the engine run either rich or lean. Usually, the internal resistance of these sensors changes with temperature.

Engine Coolant Temperature Sensor Service

A ***bad engine coolant temperature sensor*** can affect air-fuel ratio and ignition timing by sending an incorrect signal to the computer. The coolant temperature sensor richens the mixture when cold and leans the mixture when hot. If open, the sensor might affect cold engine driveability. If shorted, it might affect warm engine driveability.

If the on-board diagnostics indicate a problem, a digital ohmmeter is often recommended for pinpoint testing an engine coolant temperature sensor. The service manual will give resistance values for various temperatures. If the ohmmeter test readings are not within specs for each temperature value, the sensor is bad and must be replaced.

Note!
Temperature sensor operation and ratings can vary. When purchasing any new sensor, make sure you have the *right one*. If you install the wrong sensor, it will upset the operation of the engine management system and negatively affect engine performance.

When replacing an engine coolant temperature sensor, use a deep socket or six-point wrench to unscrew the old unit. You might want to coat the sensor threads with an approved sealer. Then, start the sensor in the engine by hand and tighten it with your wrench. Do not overtighten the sensor or it could bottom out in the engine and be ruined.

Intake Air Temperature Sensor Service

A ***bad intake air temperature sensor*** usually will not have a pronounced effect on engine operation. It allows the computer to make fine adjustments of air-fuel ratio and timing with changes in outside air temperature. If the sensor fails, it will normally trigger a trouble code, signaling you to test the sensor and its circuit. A faulty air temperature sensor can make the engine hard to start or cause the engine to run lean after it has warmed up.

A scan tool or an ohmmeter is commonly used for checking an intake air temperature sensor. As with an engine coolant temperature sensor, the unit is frequently a thermistor that changes internal resistance with temperature. The sensor's resistance must be within specifications for certain temperatures.

Airflow Sensor Service

A ***bad airflow sensor*** can make the engine run a little lean or rich. It may also cause the system to go into limp-in mode, as will several other sensors. If the sensor is shorted or open, the computer will begin to operate on preprogrammed values. The vehicle will perform poorly and get lower fuel economy.

Since there are various types of airflow sensors, you must refer to the shop manual for exact testing procedures. Some variable resistance–type sensors can be tested with an ohmmeter. Other airflow sensors contain integrated circuits. Special testing methods are required to prevent sensor damage to these sensors. On late-model vehicles, the scan tool will indicate a problem with an airflow sensor.

If the airflow sensor is faulty, it must be replaced. During replacement, make sure you have the correct unit. Also, tighten all fittings carefully. An *air leak* after the airflow sensor will upset its operation, and can trigger trouble codes.

Servicing Other EFI Sensors

The other sensors in an electronic fuel injection system are tested using the same general procedures just discussed. You would use the self-diagnosis mode, a special analyzer, or a digital meter to check each sensor. Refer to a service manual for exact procedures.

Note!
For detailed information on sensor service, refer to index. Sensor testing and replacement is covered in numerous chapters.

Control Module Service

When diagnostic trouble codes and/or pinpoint tests indicate a faulty control module, the module must generally be replaced. Procedures for replacing a control module vary from manufacturer to manufacturer. Always refer to an appropriate service manual for specific instructions.

As discussed in Chapter 17, a ***PROM*** (programmable read only memory) is an integrated circuit chip found in all control modules. In many late-model vehicles, this chip cannot be removed from the control module. In older vehicles (pre-OBD II), however, the original PROM can be removed from the faulty control module and reused in the new unit. This will ready the new control module for a specific vehicle. See **Figure 23-26.**

The control module is normally mounted under the dash. This keeps the electronic circuits away from engine heat and vibration. In a few vehicles, however, the control module is in the engine compartment.

Note!
Control module system operation, diagnosis, and repair are detailed in Chapters 17, 18, and 19.

Gasoline Injection Adjustments

There are several tune-up adjustments needed on a gasoline injection system. These include:

- Engine idle speed adjustment, **Figure 23-27.**
- Throttle plate stop adjustment.
- Idle air-fuel mixture adjustment.
- Throttle cable adjustment.

Since there are so many types of systems, refer to a service manual for exact procedures. **Figure 23-28** shows a wiring diagram for a typical electronic fuel injection system.

Tech Tip!
Many automakers warn against making some adjustments on a gasoline injection system. For example, only make mixture adjustments when major problems exist or an exhaust analyzer shows high emission levels. If you must make large adjustments, there are usually other problems in the system.

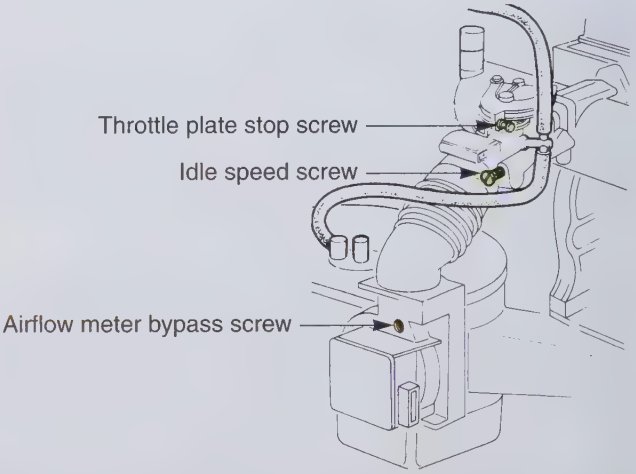

Figure 23-27. Adjustments and their access locations will vary with the particular model and type of gasoline injection system. These are typical of one system.

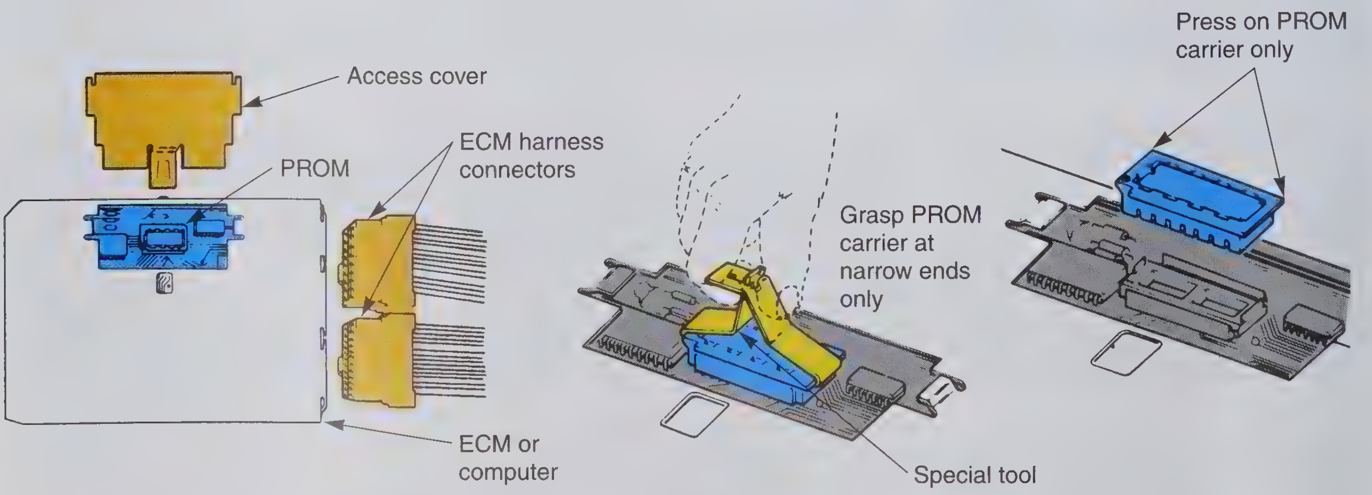

Figure 23-26. When tests find a faulty control module, you may need to replace the entire module. Sometimes, however, the PROM (computer chip calibrated for exact engine) must be reused. A—Unplug the control module and remove the access cover. B—Pull the PROM out using a special tool. C—When installing a new PROM, keep your fingers off the chip itself. Press only on the outer carrier. (General Motors)

Testing Idle Control Motor

A ***bad idle speed motor*** may not be able to maintain the correct engine idle speed. Engine idle speed may be too low or too high for conditions. The servo motor could have shorted windings, open windings, worn internal parts, or other problems.

To check an idle speed motor, jump battery voltage to specific terminals on the servo motor. This should make the idle speed motor plunger retract and extend as the connections are reversed. Pulling off a large vacuum hose should also make the idle motor plunger retract, lowering idle speed. A faulty motor will usually not function.

If the idle speed motor works when jumped to battery voltage, check wiring leading to motor. The wiring harness could have an open or short. A control module or relay problem could also prevent motor operation.

Idle Air Control Valve Service

A ***bad idle air control valve*** will upset engine idle speed like a bad idle speed motor. It uses solenoid action to open and close an air passage that bypasses the throttle plates. In this way, it can increase or decrease engine idle rpm. If it fails, engine rpm will be constant and may not increase with a cold engine or decrease as the engine warms to operating temperature.

To check the idle air control valve, jump battery voltage to the windings. This should trigger the solenoid and change engine speed. If the engine speed does not change, check for carbon buildup and blockage in the passage at the idle air control valve before replacing the unit. An ohmmeter may also be recommended to check the windings.

Idle Air Control Motor Tester

An ***idle air control motor tester*** energizes the solenoid or servo motor to check its affect on engine idle speed. See **Figure 23-29.** Disconnect the wiring going to the idle air motor. Connect the tester harness to the motor.

As you press the up arrow on the tester, engine idle speed should increase. As you press the down arrow, engine idle speed should decrease. If engine idle speed does not change, you may have a bad idle air control motor, clogged passage, or bad vacuum leak.

If the tester shows a functioning idle air control motor, check that the control module is sending the right amount of voltage to the motor. You could have an open in the wiring or control module problem.

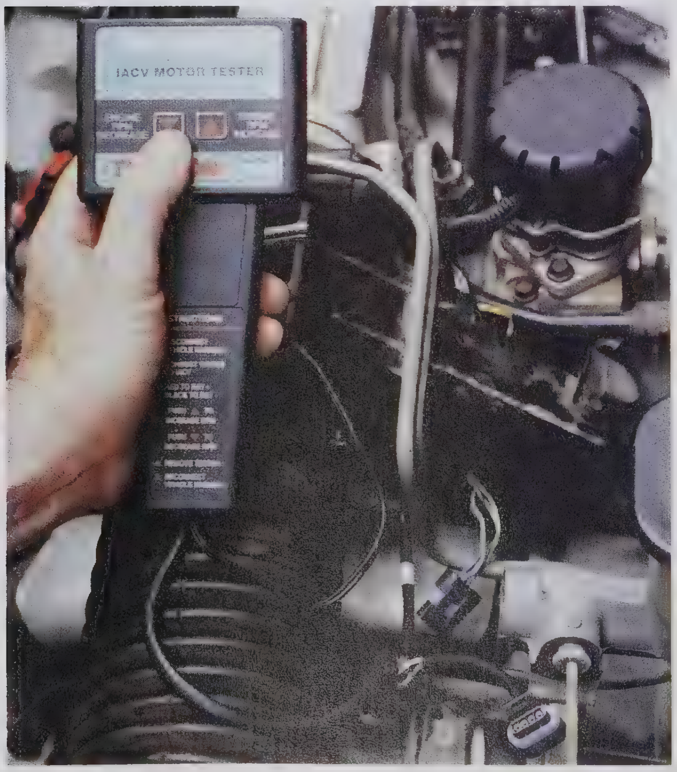

Figure 23-29. Idle air control motor tester will quickly determine if the motor is capable of altering engine idle speed. Install the tool on the idle air control motor connector and idle the engine. Pushing the buttons should allow you to increase and decrease engine idle speed. If not, check for passage restrictions or a failed motor.

Multiport Throttle Body Service

The service of a multiport throttle body usually involves replacing dried, deteriorated gaskets and seals. Basically, remove the throttle body from the engine. Disassemble the unit while keeping all parts organized. Inspect moving parts for wear. The throttle shaft and its bushings can wear with prolonged service, requiring replacement. Install new gaskets and seals and reassemble the unit in reverse order of disassembly.

Figure 23-30 shows an exploded view of a modern throttle body assembly. Note the location of the seals and gaskets that must sometimes be replaced.

Duff's Garage

Problem: Mr. Buckley walks into the shop, upset because no one has been able to fix his 1999 Jeep Cherokee. He explains to Duff that he has taken the car to three shops and none of them has corrected the problem. As he was driving the car home from another repair shop, it stalled right in front of Duff's garage.

Diagnosis: Duff questions Mr. Buckley about the exact nature of the problem. Mr. Buckley explains that the car runs fine for about a half hour and then the engine just stops. He adds that other shops have checked the fuel pressure, the injectors, and the ignition system. A new fuel filter, ignition module, and air filter have been installed. The strange thing, according to Mr. Buckley, is that the engine will start again after about 15 minutes and will run fine for another half hour.

Duff starts the vehicle and allows it to run until it stalls. He then cranks the engine to verify the no-start condition. After allowing the vehicle to sit for a while, Duff is able to restart the engine. Duff turns the job over to one of the shop's experienced service technicians, who knows to check for "spark and fuel" when there is a no-start problem.

The technician starts the engine and allows it to run until it stalls. She then pulls a plug wire and checks for spark. A strong electric arc is seen jumping to ground.

The technician then suspects that the fuel system may be at fault. When she uses a screwdriver to depress the service valve on the fuel rail, no fuel squirts out. This indicates that there is no fuel pressure. She hooks up a fuel pressure gauge and starts the vehicle. The gauge indicates normal system pressure.

Figure 23-30. Service of throttle body for multiport fuel injection is similar to if not easier than servicing a TBI unit. Gaskets and seals sometimes require replacement. Check the throttle shaft for wear. Reinstall the sensors and IAC motor properly. (Chevrolet)

At this point, the technician suspects that something is restricting fuel flow to the engine at the time of the malfunction. She removes the fuel tank sending unit and inspects the inlet filter. The sock-type filter is coated with fuel residue. A crease in the filter indicates that the filter has been collapsing, stopping fuel flow. She determines that suction from the fuel pump is causing the restricted filter to collapse.

Repair: The technician installs a new in-tank fuel filter. She then starts the vehicle and allows it to run long enough to make sure the problem has been solved. Finally, she releases the vehicle to its owner.

Summary

- Most EFI systems have self-diagnostic (self-test) abilities which means the on-board control module can detect and record possible faults.
- When a malfunction indicator light in the dash glows, it tells the driver and technician that something is wrong.
- A scan tool will find and display many problems related to an electronic fuel injection system.
- A faulty fuel pressure regulator can cause an extremely rich or lean mixture. A bad injector can cause a wide range of problems: rough idle, hard starting, poor fuel economy, engine miss, etc.

- A throttle body rebuild involves replacing all gaskets, seals, and other worn parts.
- To quickly make sure each EFI injector is opening and closing, place a stethoscope (listening device) against each injector.
- A noid light is a special test light for checking electronic fuel injector feed circuits.
- An injector balance test uses a fuel injector tester to measure the amount of fuel flowing through each injector.
- A fuel injector cleaning tool uses shop air pressure to force a cleaning solution through the injectors to remove deposits.

Review Questions—Chapter 23

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What four things must be used when diagnosing problems in a gasoline injection system?
2. Explain the EFI self-diagnostic mode found on many late-model cars.
3. How does an EFI tester work?
4. An oscilloscope can sometimes be used to view the electrical waveforms at the injectors for checking the control module, wiring, and injector coil. True or False?
5. Many EFI systems can maintain a fuel pressure as high as _____ psi or _____ kPa.
6. Which of the following does *not* pertain to a fuel pressure regulator?
   (A) Can cause a rich fuel mixture.
   (B) Can cause a lean fuel mixture.
   (C) Tested with a dwell meter.
   (D) Tested with a pressure gauge.
7. Where are the locations of the fuel pressure regulators with throttle body and multiport injection?
8. An engine with electronic multiport injection has a rough idle, as if one cylinder is dead (not firing). The ignition system and engine are in good condition. Technician A says that a stethoscope should be used to listen to each injector. One of the injectors may not be operating (making a clicking sound). Technician B says that all the injectors should be removed and checked for a proper spray pattern. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. An engine with electronic throttle body injection will not run. The ignition is producing adequate spark and the engine is in good condition. Technician A says that the fuel pressure should be measured. The pressure regulator may be bad or there may be a clogged fuel filter. Technician B says that you should remove the air filter and look inside the throttle body while trying to start the engine. This will show you if the EFI system is working. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. List nine rules to follow when replacing a throttle body injector.
11. An ohmmeter can be used to check an EFI injector coil for shorts or opens. True or False?
12. Why is injector fuel volume output important?
13. How do you perform an electronic fuel injector balance test?
14. When testing EFI sensors, a digital meter is better than a conventional needle-type meter because it draws less current. True or False?
15. A throttle position sensor should produce a given amount of _____ for different throttle openings.
16. An oxygen sensor is very sensitive and can be damaged if tested improperly with a VOM. True or False?

17. A(n) _____ _____ is often recommended for testing an EFI temperature sensor.
18. What is an EFI system PROM?
19. Where is the EFI system control module normally mounted?
20. List and explain four gasoline injection system adjustments.
21. Many automakers warn against making some gasoline injection system adjustments unless absolutely necessary. True or False?
22. Oxygen sensors are normally designed to last about _____ miles or _____ km.
23. A faulty oxygen sensor will usually be locked at _____ _____ _____ and will *not* _____.
24. How do you adjust a throttle position sensor?
25. A black oxygen sensor tip normally indicates a(n) _____ mixture and _____ contamination.

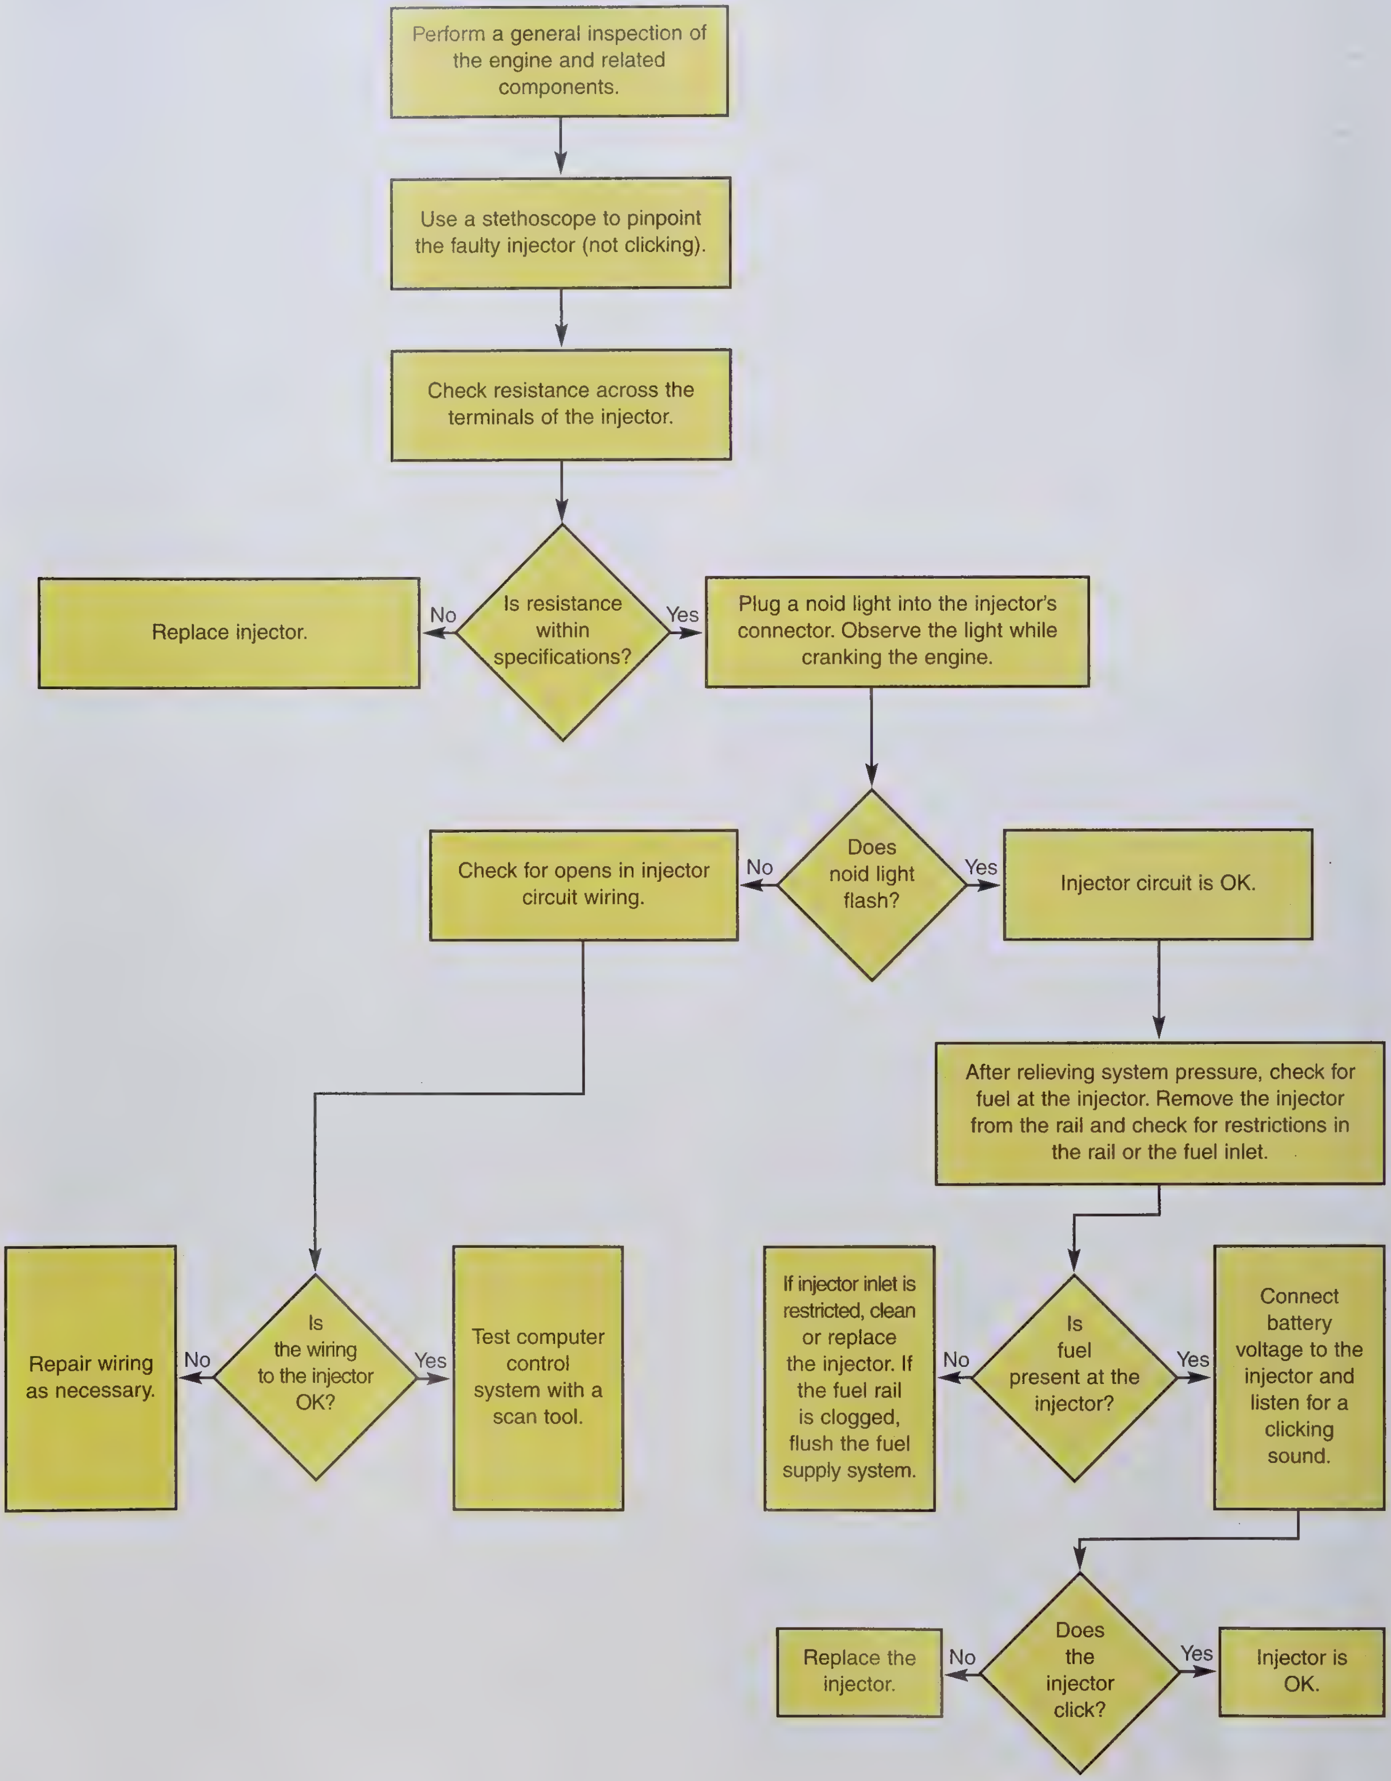
ASE-Type Questions

1. Which of the following can be used to test voltage values at EFI injectors?
   (A) Oscilloscope.
   (B) Milliammeter.
   (C) Ohmmeter.
   (D) All of the above.
2. A faulty fuel pressure regulator can cause:
   (A) an extremely rich fuel mixture.
   (B) an extremely lean fuel mixture.
   (C) Either A or B.
   (D) Neither A nor B.
3. After testing a fuel pressure regulator and finding pressure low, Technician A suggests checking the fuel pump before actually replacing the regulator. Technician B proposes checking the fuel filters before replacing the regulator. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
4. Which of the following is *not* a common fuel pressure regulator location?
   (A) On the fuel rail.
   (B) On control solenoid.
   (C) On throttle body assembly.
   (D) On a branch connected to fuel injectors.
5. Which injector problem can create a lean air-fuel mixture?
   (A) Dirty injector.
   (B) Leaking injector.
   (C) Stuck open injector.
   (D) All of the above.
6. Electronic fuel injection pressure can reach:
   (A) 20 psi.
   (B) 30 psi.
   (C) 60 psi.
   (D) 100 psi.
7. Which of the following can be used to *quickly* check EFI multiport injector operation?
   (A) Ohmmeter.
   (B) Oscilloscope.
   (C) EFI analyzer.
   (D) Stethoscope.
8. If an EFI multiport injector is removed for service, manufacturers suggest replacing the:
   (A) boot.
   (B) hose.
   (C) seals.
   (D) All of the above.
9. An injector balance test shows a below normal pressure drop on one injector. Technician A says to try running cleaning solution through the injector. Technician B says that the injector is bad and should be replaced. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
10. Typical oxygen sensor output should be about:
    (A) 0.5 volts.
    (B) 0.6 volts.
    (C) 0.8 volts.
    (D) 0.10 volts.

Activities—Chapter 23

1. Study the fuel injection section of any shop manual given to you by your instructor. Develop a "diagnosis tree" for an injector that is not working.
2. Develop an overhead transparency showing various injector spray patterns. Using the transparency, explain the patterns to the class.
3. Demonstrate the proper procedure for replacement of a multiport injector.

Gasoline Injection System Diagnosis



Perform a general inspection of the engine and related components.
Use a stethoscope to pinpoint the faulty injector (not clicking).
Check resistance across the terminals of the injector.
Is resistance within specifications?
No
Replace injector.
Yes
Plug a noid light into the injector's connector. Observe the light while cranking the engine.
Does noid light flash?
No
Check for opens in injector circuit wiring.
Yes
Injector circuit is OK.
After relieving system pressure, check for fuel at the injector. Remove the injector from the rail and check for restrictions in the rail or the fuel inlet.
Is the wiring to the injector OK?
No
Repair wiring as necessary.
Yes
Test computer control system with a scan tool.
Is fuel present at the injector?
No
If injector inlet is restricted, clean or replace the injector. If the fuel rail is clogged, flush the fuel supply system.
Yes
Connect battery voltage to the injector and listen for a clicking sound.
Does the injector click?
No
Replace the injector.
Yes
Injector is OK.

24

Carburetor Fundamentals

After studying this chapter, you will be able to:

- Describe and identify the basic parts of a carburetor.
- Compare carburetor design differences.
- List and explain the fundamental carburetor systems.
- Explain special carburetor devices.
- Describe the operation of computer-controlled carburetors.
- Correctly answer ASE certification test questions that require a knowledge of the fundamentals of carburetors.

Even though gasoline engines now have electronic fuel injection, millions of older cars and trucks on the road today are equipped with carburetors. These vehicles commonly need service and repair. This makes a basic understanding of carburetor operation and repair important to today's technician.

This chapter introduces the fundamental principles of carburetion. It discusses carburetor systems, design differences, auxiliary control devices, and computer control. It will prepare you to study the service and repair of carburetors in the next chapter.

Basic Carburetor

A ***carburetor*** is basically a device that mixes air and fuel in the correct proportions (amounts) for efficient combustion.

The carburetor bolts to the engine's intake manifold. The air cleaner fits over the top of the carburetor to trap dust and dirt. See **Figure 24-1.**

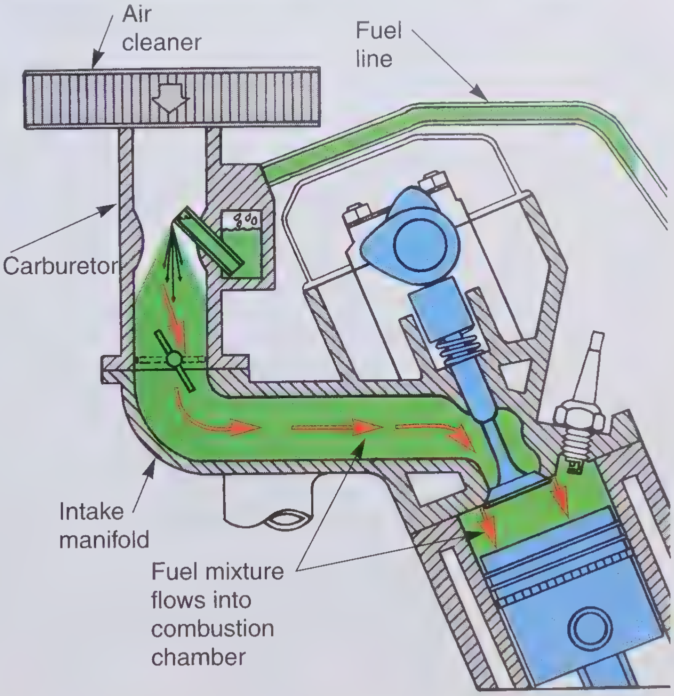


Figure 24-1. The carburetor bolts to the engine intake manifold. It meters and mixes fuel with incoming air.

When the engine is running, downward-moving pistons on their intake strokes produce a suction (low-pressure area) in the intake manifold. Air rushes through the carburetor and into the engine to fill this low-pressure area. The airflow through the carburetor is used to meter fuel and mix it with the air.

Basic Carburetor Parts

Many carburetor parts perform the same functions as corresponding gasoline injection system parts, **Figure 24-2**. The basic parts of a carburetor are shown in **Figure 24-3**. Refer to this illustration as these parts are introduced.

The ***carburetor body*** is a cast metal housing for the other carburetor components. It contains cast and drilled passages for air and fuel. The main discharge tube, venturi, and fuel bowl are normally integral parts of the

Carburetor System	Gasoline Injection System	Part Function
Choke	Engine temperature sensor, manifold temperature sensor, or cold start injector	Meters in more fuel for cold engine operation
Float	Fuel pressure regulator, electric fuel pump	Provides additional supply of fuel
Idle circuit	Air bypass valve, idle control motor, engine speed sensor	Meters air/fuel at low speeds
Accelerator pump	Throttle position switch, manifold pressure sensor	Enriches fuel mixture for acceleration
Fast idle cam	Throttle positioner or air bypass valve	Increases idle speed of cold engine
Power valve or metering rod	Manifold pressure sensor, throttle position switch, oxygen sensor	Enriches mixture for rapid acceleration
Fuel metering jets or mixture control solenoid	Injector valves, fuel pressure regulator	Meters fuel into right amount of air
Throttle valves	Throttle valves	Controls engine speed and power
Carburetor body	Throttle body	Houses throttle valve and idle speed device
Venturi and main discharge	Airflow sensor	Measures amount of air entering engine
System computer (if used)	System computer	Monitors and controls system
System sensors (if used)	System sensors	Measure operating conditions

Figure 24-2. A carburetor fuel system can be compared to a gasoline injection system. Study the parts and their functions. This will help you understand carburetor operation.

carburetor body. A flange on the bottom of the body allows the carburetor to be bolted to the engine.

The carburetor ***air horn,*** also called ***throat*** or ***barrel,*** routes outside air into the engine intake manifold, **Figure 24-3.** It contains the throttle valve, venturi, and outlet end of the main discharge tube.

The ***throttle valve*** is a butterfly valve located in the air horn. It controls the power output of a gasoline engine. When the throttle valve is closed, it restricts airflow through the carburetor. This reduces the amount of fuel flowing into the engine.

A ***venturi*** produces sufficient suction to pull fuel out of the main discharge tube. Venturi action is illustrated in **Figure 24-4.** Vacuum is highest inside the venturi. The narrowed airway increases air velocity, forming a low-pressure area in the air horn.

The ***main discharge tube*** uses venturi vacuum to feed fuel into the air horn and engine. Also called ***main fuel nozzle,*** it is a passage in the carburetor body and air horn that connects the fuel bowl to the center of the venturi. Refer to **Figure 24-3.**

The carburetor ***fuel bowl*** holds a supply of fuel that is *not* under fuel pump pressure. Several additional carburetor parts are mounted in the fuel bowl. These will be discussed later.

Basic Carburetor Systems

A ***carburetor system*** is a network of passages and related parts that helps control the air-fuel ratio under a specific engine operating condition. Also called a ***carburetor circuit,*** each system supplies a predetermined

Figure 24-4. A venturi is used to produce vacuum from airflow. Note how the vacuum is highest inside venturi. (Ford)

air-fuel mixture as the temperature, speed, and engine load change.

For example, a gasoline engine's air-fuel mixture may vary from a rich 8:1 ratio to a lean 18:1 ratio, depending on operating conditions. An automotive carburetor, using its various systems, must be capable of providing varying air-fuel ratios:

- 8:1 for cold engine starting.
- 16:1 for idling.
- 15:1 for part throttle.
- 13:1 for full acceleration.
- 18:1 for normal cruising at highway speeds.

The seven basic carburetor systems are the float, idle, off-idle, acceleration, high-speed, full-power, and choke systems.

Float System

The ***float system*** must maintain the correct level of fuel in the carburetor bowl. The float system keeps the fuel pump from forcing too much gasoline into the carburetor bowl. Look at **Figure 24-5.**

The ***carburetor float*** rides on top of the fuel in the bowl to open and close the needle valve. It is normally made of thin brass or plastic. One end of the float is hinged to the side of the carburetor body. The other end is free to swing up and down.

The ***needle valve*** in the top of the fuel bowl regulates the amount of fuel passing through the fuel inlet and needle seat.

The ***needle seat*** works with the needle valve and float to control fuel flow into the bowl. It is a brass fitting that threads into the carburetor body, **Figure 24-5.**

A ***bowl vent*** prevents a pressure or vacuum buildup in the carburetor fuel bowl. Without venting, pressure could form in the bowl as the fuel pump fills the carburetor. This could also cause vacuum to form in the bowl as fuel is drawn out of the carburetor and into the engine.

When engine speed or load increases, fuel is rapidly pulled out of the fuel bowl and into the venturi. Illustrated in **Figure 24-6,** this makes the fuel level and

Needle valve
Float
Bowl

Figure 24-5. Basic parts of a float system. The float opens and closes a needle valve as the fuel level falls and rises. Study the part names.

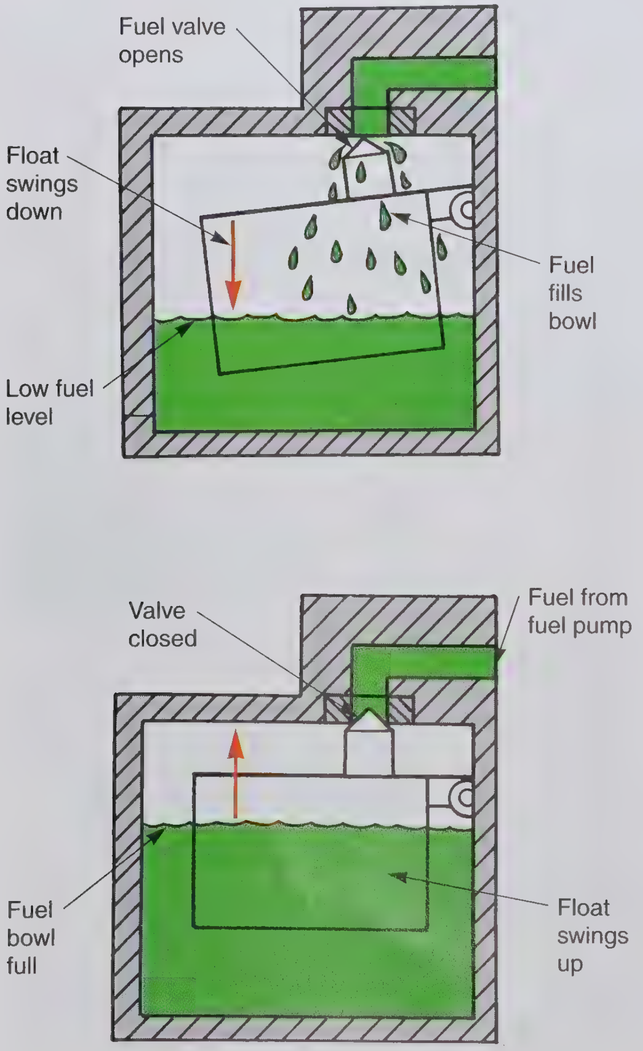
float drop in the bowl. The needle valve also drops away from its seat. The fuel pump can then force more fuel into the bowl.

As the fuel level in the bowl rises, the float pushes the needle valve back into the seat. When the fuel level is high enough, the float closes the opening between the needle valve and seat.

When the engine is running, the needle valve usually lets some fuel leak into the bowl. As a result, the float system maintains a stable quantity of fuel. This is very important because the fuel level in the bowl can affect the air-fuel ratio.

Idle System

A carburetor's ***idle system*** provides the engine's air-fuel mixture at speeds below approximately 800 rpm or 20 mph (32 km/h).



Fuel valve opens
Float swings down

Figure 24-6. Basic float operation.

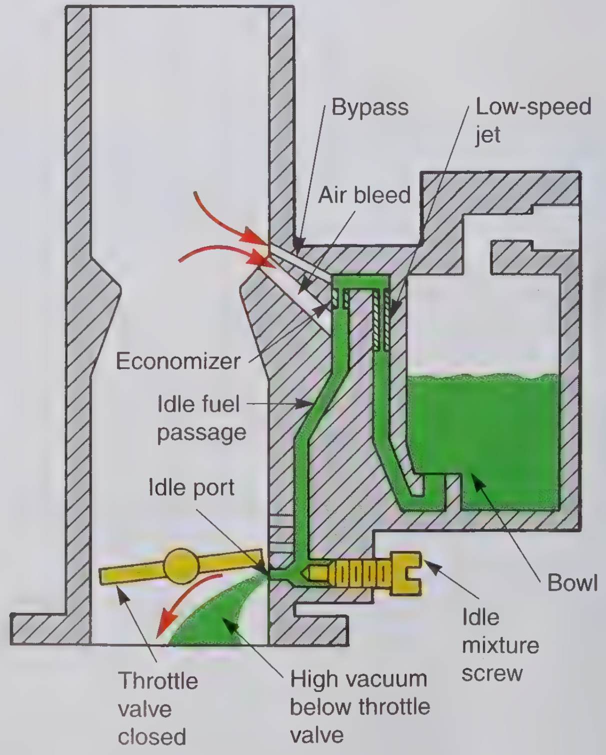
When an engine is idling, the throttle valve is almost closed. Airflow through the air horn is too restricted to produce enough vacuum in the venturi. Venturi vacuum cannot pull fuel out of the main discharge tube. Instead, the high intake manifold vacuum *below* the throttle plate and a separate idle circuit are used to feed fuel into the air horn. The parts of an idle system are shown in **Figure 24-7.**

The ***low-speed jet*** is a restriction in the idle passage that limits maximum fuel flow in the idle circuit. It is placed in the fuel passage before the idle air bleed and economizer.

The ***idle air bleed*** works with the ***economizer*** and ***bypass*** to add air bubbles to the fuel flowing to the idle port. The air bubbles help break up, or atomize, the fuel. This makes the air-fuel mixture burn more efficiently once in the engine.

The ***idle passage*** carries the air-fuel slurry (mixture of liquid fuel and air bubbles) to the idle screw port. The ***idle screw port*** is an opening into the air horn below the throttle valve.

The ***idle mixture screw*** allows adjustment of the size of the opening in the idle port. Turning the idle screw *in* reduces the size of the idle port. This reduces the amount of fuel entering the air horn, producing a leaner fuel



Bypass

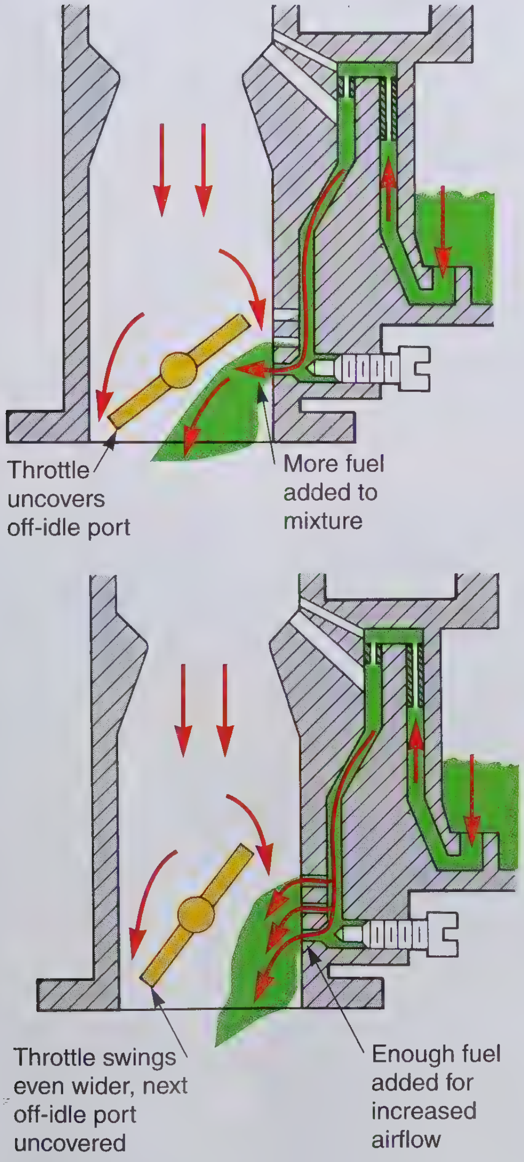
High vacuum below throttle valve

Figure 24-7. The idle system feeds fuel into the air horn when the throttle is closed for low engine speed operation. High vacuum below the throttle pulls fuel out of the idle port. A mixture screw allows adjustment of the mixture at idle. An air bleed helps premix the air and fuel.

mixture at idle. Turning the idle screw *out* increases the size of the idle port and the amount of fuel flowing into the air horn, enriching the fuel mixture at idle.

Tech Tip!
Idle mixture screw adjustment is critical to exhaust emissions. Therefore, most late-model carburetors have ***sealed idle mixture screws.*** These idle mixture screws are covered with metal plugs to prevent tampering with the factory idle mixture setting.
Sometimes, plastic ***limiter caps*** are pressed over the heads of the idle mixture screws. The caps restrict how far the screws can be turned toward either rich or lean settings.



Throttle uncovers off-idle port
More fuel added to mixture
Throttle swings even wider, next off-idle port uncovered
Enough fuel added for increased airflow

Figure 24-8. Off-idle system feeds fuel to the engine when the throttle is opened slightly. It adds a little extra fuel to the extra air flowing around throttle valve.

For the idle system to function, the throttle plate must be closed. Then, high intake manifold vacuum can pull fuel out of the idle circuit.

Off-Idle System

The ***off-idle system,*** often termed the ***part throttle circuit,*** feeds more fuel into the air horn when the throttle plates are partially open. Look at **Figure 24-8.** This system is an extension of the idle system. It functions *above* 800 rpm or 20 mph (32 km/h).

Without the off-idle system, the fuel mixture would become too lean slightly above idle. The off-idle system helps supply fuel during the transition (change) from idle circuit to high-speed circuit. The off-idle system begins to function when the driver presses lightly on the accelerator, cracking open the throttle plates.

Figure 24-9 shows the bottom of a carburetor air horn. Notice the idle screw port, idle screw tip, and off-idle ports. Note that the throttle plate exposes all the ports to vacuum when it is partially opened.

Acceleration System

The carburetor's ***acceleration system,*** like the off-idle system, provides extra fuel when changing from the idle circuit to the high-speed circuit (main discharge).

The acceleration system "squirts" a stream of extra fuel into the air horn whenever the accelerator is

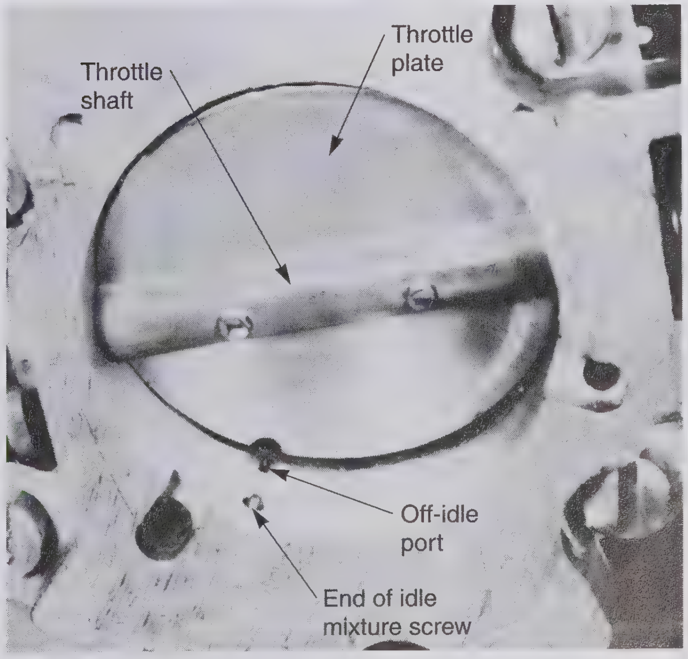


Figure 24-9. Bottom view of a carburetor shows the idle mixture screw tip, idle port opening, and off-idle port. (Carter Carburetor Div.)

pressed (throttle valves swing open). This is illustrated in **Figure 24-10.**

Without the acceleration system, too much air would rush into the engine as the throttle is quickly opened. The mixture would become too lean for combustion, and the engine would *hesitate* or *stall.* The acceleration system prevents a lean air-fuel mixture from upsetting a smooth increase in engine speed.

The ***accelerator pump*** develops the pressure to force fuel out of the pump nozzle and into the air horn. There are two types of accelerator pumps: piston pumps and diaphragm pumps. See **Figures 24-11** and **24-12.**

The ***pump check ball*** allows fuel to only flow into the pump reservoir. It stops fuel from flowing back into the fuel bowl when the pump is actuated.

The ***pump check weight*** prevents fuel from being pulled into the air horn by venturi vacuum. Its weight seals the passage to the pump nozzle and prevents fuel siphoning.

The ***pump nozzle,*** or ***pump jet,*** has a fixed orifice (opening) that helps control fuel flow out of the pump circuit. It also guides the fuel stream into the center of the air horn.

When the driver presses the accelerator, the throttle plates swing open. This causes the accelerator pump piston or diaphragm to compress the fuel in the pump reservoir.

The accelerator pump pressure closes the pump check ball and the fuel flows toward the pump check weight. Pressure lifts the pump check weight off its seat, and fuel squirts into the carburetor air horn, as if from a *toy squirt gun.*

A spring is used on the accelerator pump assembly to produce a smooth, steady flow of fuel out of the pump

nozzle. Throttle opening compresses the spring. Then the compressed spring pushes on the pump piston to pressurize the fuel and produce prolonged fuel flow.

As the accelerator is released, the pump piston or diaphragm retracts. This closes the check weight and opens the pump check ball. Fuel flows out of the bowl to refill the accelerator pump reservoir. The system is then ready to spray another stream of fuel into the air horn when the vehicle accelerates.

High-Speed System

The carburetor's ***high-speed system,*** also called ***main metering system,*** supplies the engine's air-fuel mixture at cruising speeds, **Figure 24-13.**

This circuit begins to function when the throttle plates are open wide enough for venturi action to occur. Airflow through the carburetor must be relatively high for venturi vacuum to draw fuel out of the main discharge tube.

The high-speed system provides the leanest, most fuel efficient air-fuel ratio. It functions from about 20–55 mph (32–90 km/h) or 2000–3000 rpm.

The ***high-speed jet,*** or main jet, is a fitting with a precision hole drilled in its center. This jet screws into a threaded hole in the fuel bowl. One jet is used for each air horn.

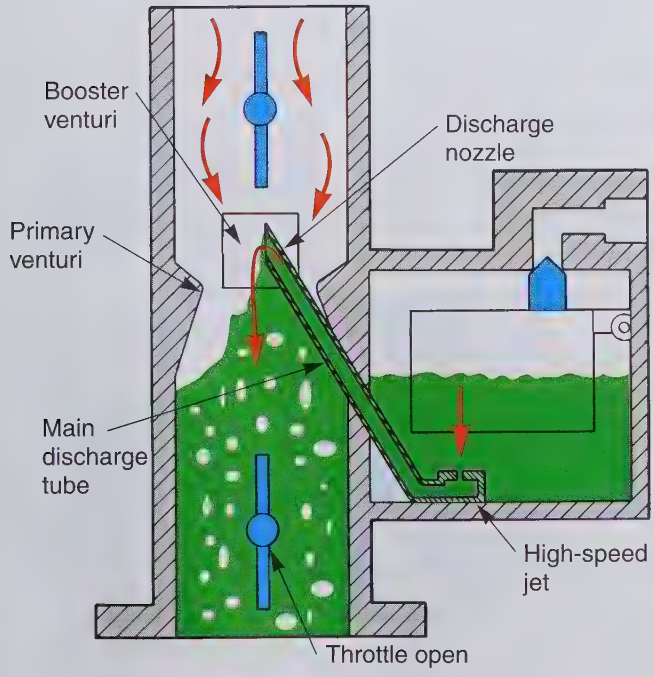

Figure 24-13. The high-speed system is simple. The main jet controls fuel flow and mixture. At higher engine speeds, there is enough airflow through the venturi to produce vacuum. This pulls fuel through the main discharge. Study the part names.

The hole size in the high-speed jet determines how much fuel flows through the circuit. A number is usually stamped on the jet to denote the diameter of the hole. Since jet numbering systems vary, refer to the carburetor manufacturer's manual for information on jet size.

The ***emulsion tube*** and the air bleed add air to the fuel flowing through the main discharge tube. The premixing of air with fuel helps the fuel atomize as it discharges into the air horn.

The ***primary venturi*** is the venturi formed in the side of the carburetor air horn. One or two ***booster venturis,*** or secondary venturis, can be added inside the primary venturi to increase vacuum at lower engine speeds.

When engine speed is high enough, airflow through the carburetor forms a high vacuum in the venturi. The vacuum pulls fuel through the main metering system. Fuel flows through the high-speed jet, which meters the amount of gasoline entering the circuit. Then, the fuel flows into the main discharge tube and emulsion tube.

The emulsion tube causes air from the air bleed to mix with the fuel. The air-fuel mixture is finally pulled out of the main nozzle and into the engine.

Full-Power System

The carburetor ***full-power system*** provides a means of enriching the fuel mixture for high-speed, high-power conditions. This circuit operates when the driver presses the gas pedal to pass another vehicle or to climb a steep hill. A simplified illustration of a full-power system is given in **Figure 24-14.**

The full-power system is usually an addition to the main metering system. Either a metering rod or a power valve (jet) can be used to provide a variable high-speed air-fuel ratio.

Metering Rod

A ***metering rod*** is a stepped rod that moves in and out of the high-speed jet to alter fuel flow. As shown in **Figure 24-15,** when the metering rod is inside the jet, flow is restricted and a leaner fuel mixture results. When the metering rod is pulled out of the jet, more fuel can flow through the system to enrich the mixture for more power output.

Either mechanical linkage, engine vacuum, or an electric solenoid and computer (modified metering rod or valve assembly) can be used to operate a metering rod. The metering rod can be linked to the throttle lever. Then, whenever the throttle is opened wide, the linkage lifts the metering rod out of the jet.

A metering rod controlled by engine vacuum is connected to a diaphragm. When power demands are low, engine vacuum is high. As power demands increase, intake manifold vacuum drops. This vacuum-load relationship is ideal for controlling a metering rod or power valve.

Figure 24-15. Metering rod action.

Power Valve

A ***power valve,*** also known as an ***economizer valve,*** performs the same function as a metering rod: it provides a variable high-speed fuel mixture. A power valve consists of a fuel valve, a vacuum diaphragm, and a spring.

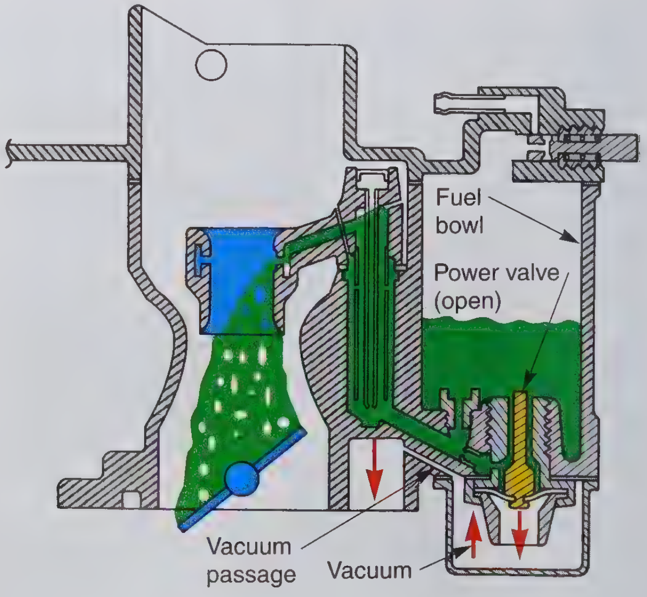
Look at **Figure 24-16.** The spring holds the power valve in the normally open position. A vacuum passage runs to the power valve diaphragm. When the power valve is open, it serves as an extra jet that feeds fuel into the high-speed circuit.

When the engine is cruising at normal highway speeds, engine intake manifold vacuum is high. This vacuum acts on the power valve diaphragm and pulls the valve closed, **Figure 24-17.** No additional fuel is added to the main metering system under normal driving conditions.

However, when the throttle plates are swung open for passing another vehicle or climbing a hill, engine manifold vacuum drops. Then, the spring in the power valve can push the valve open. Fuel flows through the power valve and into the main metering system. This adds more fuel, increasing engine power.

Choke System

The ***choke system*** is designed to supply an extremely rich air-fuel ratio to aid cold engine starting. For the fuel mixture to burn properly, the fuel entering the intake must atomize and vaporize.



Fuel bowl
Power valve (open)
Vacuum passage
Vacuum

Figure 24-16. A power valve serves the same function as a metering rod. It enriches the air-fuel mixture under high load, low intake manifold vacuum conditions. When vacuum is low, a spring opens the power valve. Extra fuel can then flow through the valve and into the main discharge.

Exhaust manifold

Figure 24-18. Basic choke system parts. The thermostatic spring is the main control of choke operation. When the engine is cold, the spring closes the choke. High vacuum below the choke pulls a large amount of fuel out of the main discharge. When the engine warms, hot air causes the spring to open the choke. The vacuum piston cracks the choke upon engine starting to prevent flooding.

When the engine is cold, the fuel entering the intake tends to condense into a liquid. As a result, not enough fuel vapors enter the combustion chambers and the engine will miss or stall. A choke is used to prevent this lean condition. See **Figure 24-18.**

The ***choke plate*** is a butterfly (disc) valve located near the top of the carburetor air horn. When the choke plate is closed, it blocks normal airflow through the carburetor. This causes high intake manifold vacuum to form below the choke plate. Vacuum pulls on the main discharge tube, even though air is not flowing through the venturi. Fuel is pulled out to prime the engine with extra fuel.

A ***thermostatic spring*** may be used to open and close the choke. The thermostatic spring is a ***bimetal spring*** (spring made of two dissimilar metals). The two metals have different rates of expansion that make the spring coil tighter when cold. It uncoils when heated. This coiling-uncoiling action is used to operate the choke.

Before the engine starts, the cold thermostatic spring holds the choke closed. When the engine is started, the closed choke causes high vacuum in the carburetor air horn. This pulls a large amount of fuel out the main discharge. The rich mixture helps keep the cold engine running.

As the engine and thermostatic spring warm, the spring uncoils and opens the choke. This produces a leaner mixture. A warm engine would not run properly if the choke were to remain closed.

Manual and Automatic Chokes

A ***manual choke*** simply uses a cable mechanism that allows the driver to open or close the choke plate. Manual chokes were used on early model vehicles. They are still found on small gas engines and heavy equipment. ***Automatic chokes,*** which open and close the choke plate with changes in temperature, are more common.

An ***integral choke*** is mounted on the side of the carburetor. It uses *warm air* from the engine to heat the thermostatic spring. An integral choke may also use engine coolant instead of warm air.

In a ***nonintegral choke,*** the thermostatic spring is mounted in the top of the intake manifold. Then, as the engine and manifold warm, the thermostatic spring uncoils to open the choke plate.

An ***electric assist choke*** uses both hot air and an electric heating element to operate the thermostatic spring. The electric assist choke system uses a temperature-sensitive switch to operate a choke heating element.

An ***all electric choke*** uses neither hot air nor coolant to aid thermostatic spring action. Instead, a two-stage heating element provides full control of choke operation. See **Figure 24-19.**

When the engine is cold, only the first stage of the heating element is activated. The thermostatic spring warms slowly to keep the choke partially closed. When the engine warms, both stages of the heating element operate. The element heats up very quickly to make the thermostatic spring open the choke.

Mechanical Choke Unloader

A ***mechanical choke unloader*** physically opens the choke plate whenever the throttle swings fully open. Look at **Figure 24-20.**

A mechanical choke unloader uses a metal lug on the throttle lever. When the throttle lever moves to the fully open position, the lug pushes on the choke linkage (fast idle linkage). This gives the driver a means of opening the choke. Air can then enter the air horn to help clear a flooded engine (engine with too much liquid fuel in the cylinders and intake manifold).

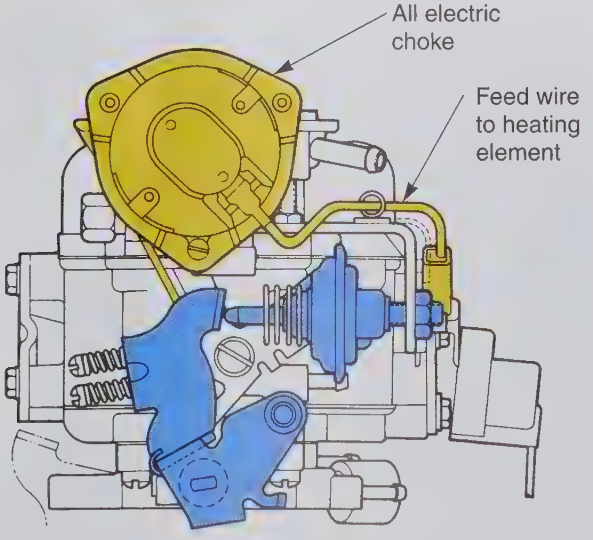

Figure 24-19. An all electric choke has a two-stage heating element. One stage warms the thermostatic spring when the engine is cold. When the engine is partially warm, both heating stages function. (Ford)

Figure 24-20. A choke unloader physically opens the choke when the accelerator pedal is pushed to the floor. The unloader lug moves the choke linkage. This lets the driver clean out a flooded engine. (Carter)

Vacuum Choke Unloader

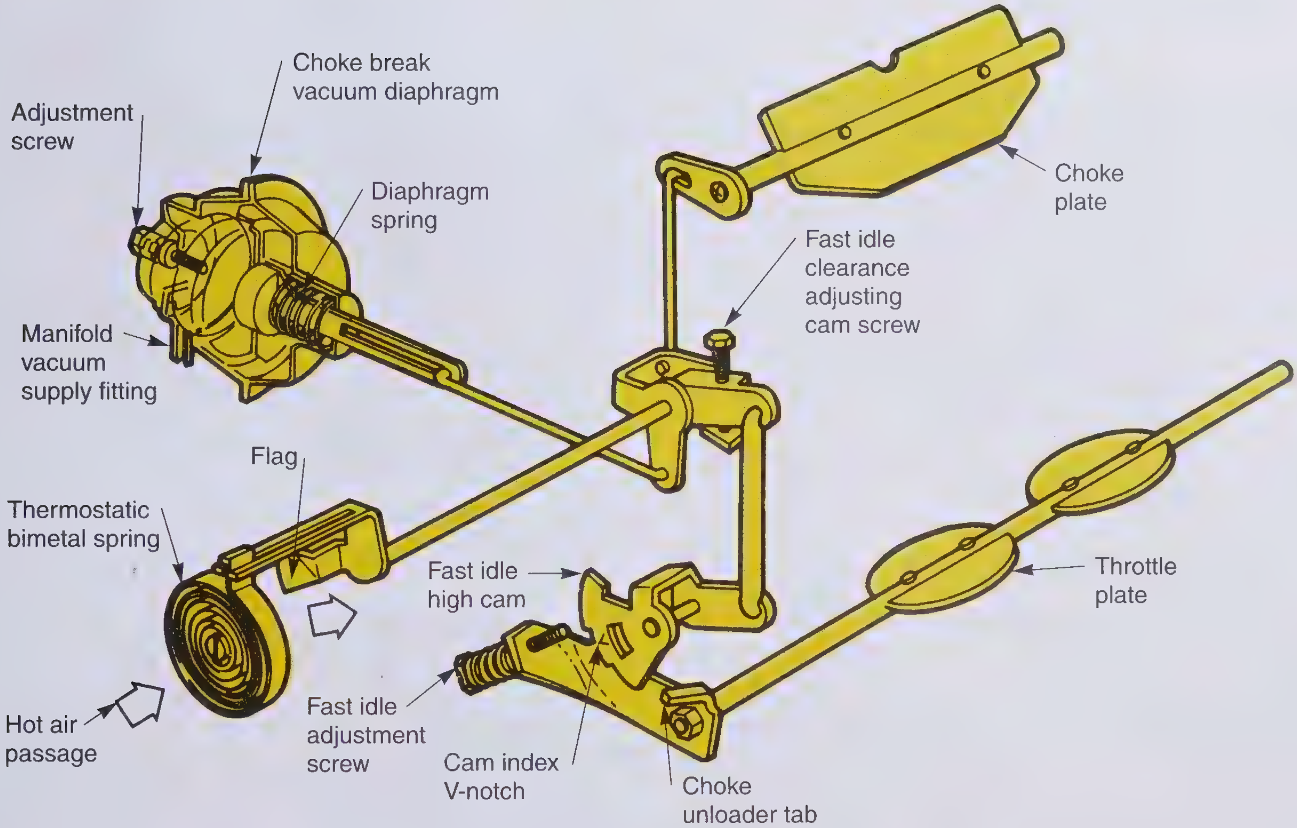
A ***vacuum choke unloader,*** also called ***choke break,*** uses engine vacuum to crack open the choke plate as soon as the engine starts. It automatically prevents the engine from flooding with too much fuel.

A vacuum choke unloader consists of a manifold vacuum fitting, vacuum hose, vacuum diaphragm (choke break), and linkage connected to the choke lever.

Before the engine starts, the choke spring holds the choke plate almost completely closed. This primes the engine with enough fuel for starting. Then, as the engine starts, intake manifold vacuum acts on the choke break diaphragm. The diaphragm pulls on the choke linkage and lever to swing the choke plate open slightly. This helps prevent an overly rich mixture and improves cold engine driveability.

Carburetor Devices

Various carburetor devices have been used over the years to increase efficiency. A few of these devices will be summarized in the following sections.



Choke break vacuum diaphragm
Adjustment screw
Diaphragm spring
Choke plate
Manifold vacuum supply fitting
Fast idle clearance adjusting cam screw
Flag
Thermostatic bimetal spring
Fast idle high cam
Throttle plate
Hot air passage
Fast idle adjustment screw
Cam index V-notch
Choke unloader tab

Figure 24-21. Note relationship of these parts. They work together to provide smooth engine operation when the engine is cold. (Ford)

Fast Idle Cam

A ***fast idle cam*** increases engine idle speed when the choke is closed. It is a stepped cam fastened to the choke linkage, **Figure 24-21.**

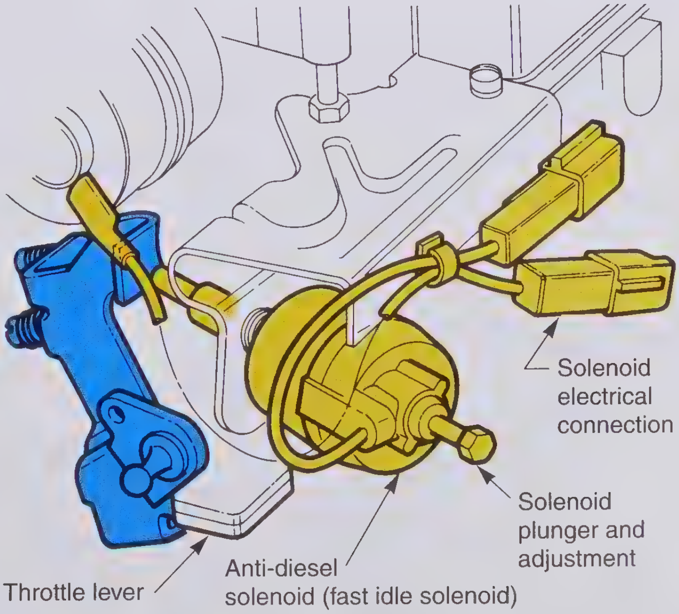
When the choke closes, the fast idle cam swings around in front of a fast idle screw. The fast idle screw is mounted on a throttle lever. As a result, the fast idle cam and fast idle screw prevent the throttle plates from closing. Engine idle speed is increased to smooth cold engine operation and prevent stalling.

As soon as the engine warms and the choke opens, the fast idle cam is deactivated. When the throttle is opened, the choke linkage swings the cam away from the fast idle screw and the engine returns to curb idle (normal, hot idle speed).

Fast Idle Solenoid

A fast idle solenoid opens the carburetor throttle plates during engine operation but allows the throttle plates to close as soon as the engine shuts off. In this way, a faster idle speed can be used while still avoiding dieseling (engine keeps running even though ignition key is turned off).

Sometimes termed an ***anti-dieseling solenoid,*** the fast idle solenoid is mounted on the carburetor so that it contacts the throttle lever, as in **Figure 24-22.**



Solenoid electrical connection
Solenoid plunger and adjustment
Anti-diesel solenoid (fast idle solenoid)
Throttle lever

Figure 24-22. A fast idle solenoid holds the throttle open when the engine is running. When the ignition key is turned off, the solenoid allows the throttle to close more. This keeps engine from dieseling, or after-running. (Ford)

Throttle Return Dashpot

A ***throttle return dashpot*** causes the carburetor throttle plates to close slowly, **Figure 24-23.** Often called an ***anti-stall dashpot,*** it is commonly used on carburetors for cars equipped with automatic transmission.

Without a throttle return dashpot, the engine could stall when it returns too quickly to an idle. The drag of the automatic transmission could "kill" the engine.

Hot Idle Compensator

A ***hot idle compensator*** is a carburetor device that prevents engine stalling or a rough idle under high engine temperature conditions. It is a temperature-sensitive valve that admits extra air into the engine to increase idle speed and smoothness.

Altitude Compensator

An ***altitude compensator*** can be used to change the carburetor's air-fuel mixture with changes in the vehicle's altitude (distance above or below sea level). An altitude compensator normally has an ***aneroid*** (bellows device that expands and contracts with changes in atmospheric pressure).

When a car is driven up a mountain, for example, the density of the air around the car decreases. This tends to make the air-fuel mixture richer. The reduced air pressure causes the aneroid to expand, opening an air valve. Extra air flows into the air horn and the air-fuel mixture becomes leaner as needed.

Carburetor Vacuum Connections

A carburetor has numerous vacuum connections. Look at **Figure 24-24.** When the vacuum connection or port is *below* the carburetor throttle plate, the port *always* receives full intake manifold vacuum. However, when the vacuum port is *above* the throttle plate, vacuum is only present at the port when the throttle is opened.

Typical components operated off carburetor vacuum connections include:

- ***EGR valve***—exhaust emission control device.
- ***Distributor vacuum advance***—diaphragm for advancing ignition timing.
- ***Charcoal canister***—emission control container for storing fuel vapors.
- ***Choke break***—diaphragm for partially opening choke when engine is running.

Carburetor Barrels

Multiple barrel carburetors are used to provide increased air intake ("engine breathing"). The amount of fuel and air that enters the engine is a factor limiting engine horsepower output. Extra carburetor barrels allow more air and fuel into the engine at wide-open throttle. This allows the engine to develop more power. See **Figure 24-25.**

Primary and Secondary

Inline two-barrel carburetors and all four-barrel carburetors have two sections: the primary and the secondary.

The ***primary*** of a carburetor includes the components that operate under normal driving conditions. In a four-barrel carburetor, the primary consists of the two front throttle plates and related components. Refer to **Figure 24-26.**

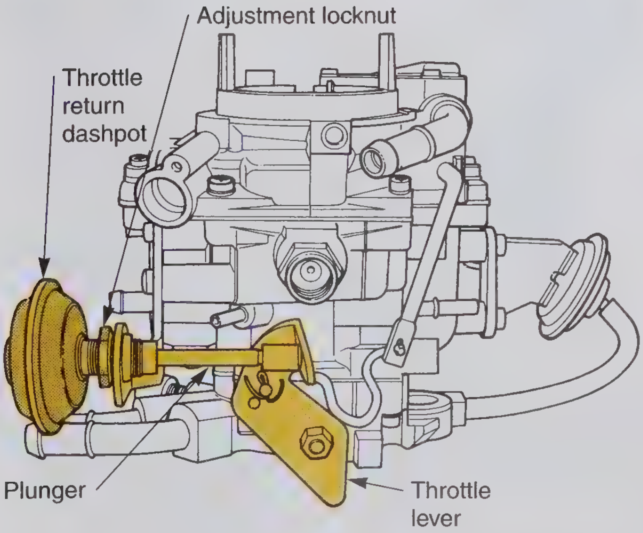


Figure 24-23. A throttle return dashpot keeps the engine from stalling when quickly returned to an idle. It is normally used on cars with an automatic transmission. The dashpot makes throttle plates close slowly. (DaimlerChrysler)

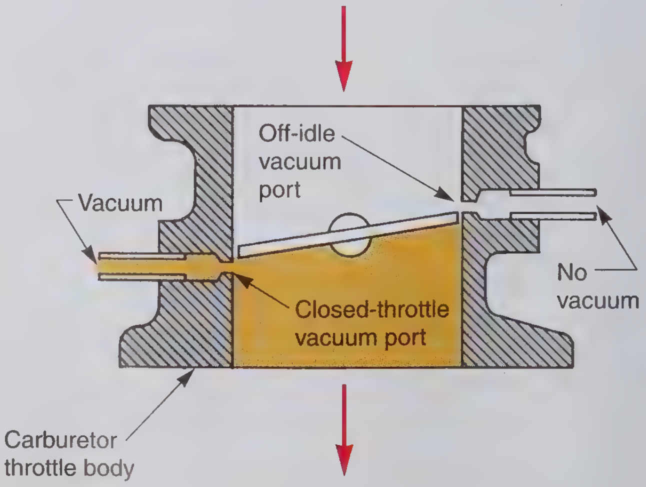

Figure 24-24. The position of the vacuum port in the carburetor determines when vacuum is present. When the port is below the throttle valve, vacuum is present at idle. When the port is above the throttle, vacuum is present above idle. (Ethyl Corp.)

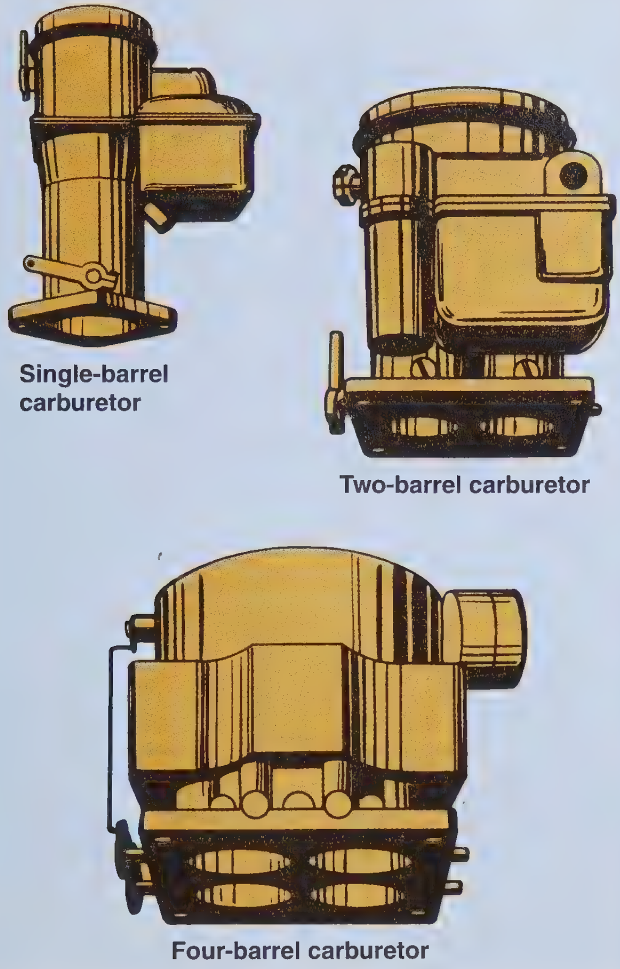


Single-barrel carburetor
Two-barrel carburetor
Four-barrel carburetor

Figure 24-25. Carburetors have one, two, or four barrels. More barrels, or air horns, are used with larger engines.

The ***secondary*** of a carburetor consists of the components or circuits that function under high engine power output conditions, **Figure 24-26.** In a four-barrel carburetor, secondary would include the two rear barrels. They only function when more fuel is needed for added power.

A ***secondary diaphragm*** is normally used to open the secondary throttle plates, causing the secondary circuits to function. As illustrated in **Figure 24-26,** a diaphragm is connected to the secondary throttle lever. A vacuum passage runs from this diaphragm to the venturi in the primary throttle bore.

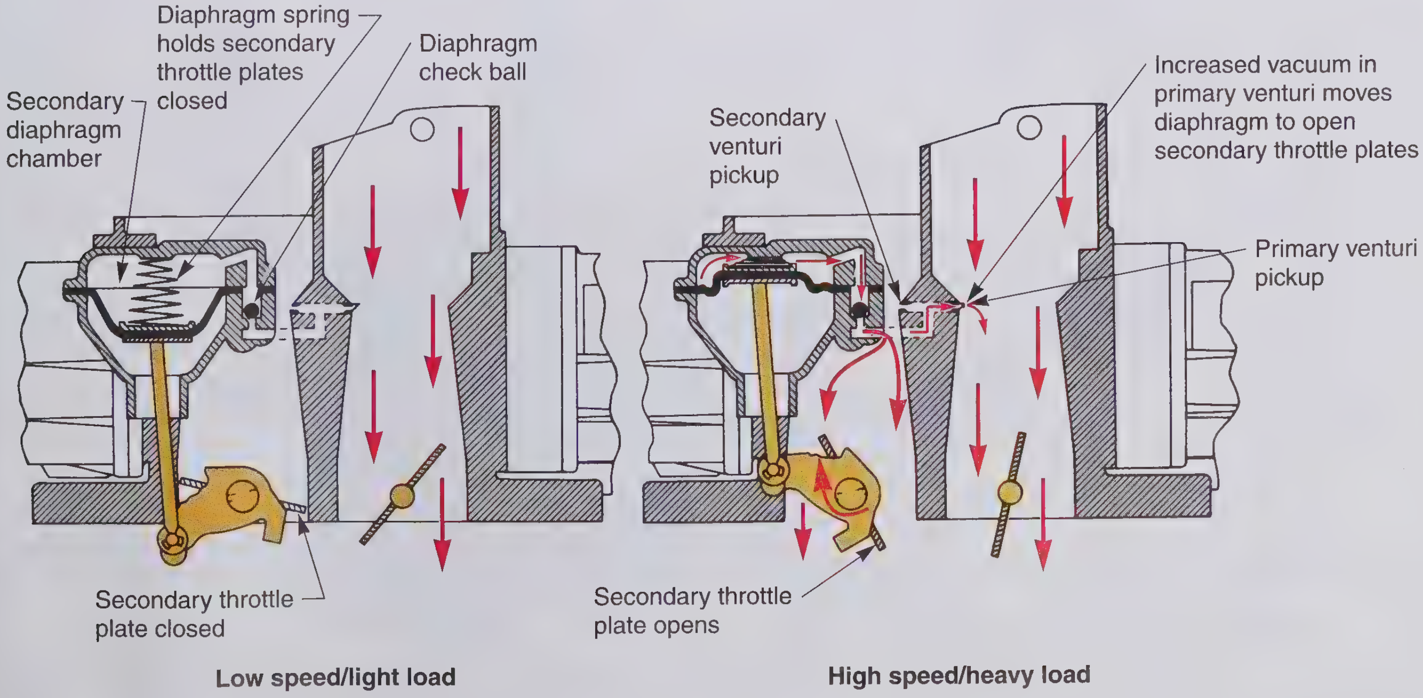
Under normal driving conditions, vacuum in the primary is *not* high enough to actuate the secondary diaphragm and throttles. The engine will run using only the primary of the carburetor.

Increased airflow in the primary (if the driver passes another vehicle, for example) produces enough vacuum to actuate the secondary diaphragm. Vacuum pulls on the diaphragm and compresses the diaphragm spring. This opens the secondary throttle plates for increased engine horsepower.

Figure 24-27 shows many of the parts just discussed. Can you explain their function?

Carburetor Size

Generally, ***carburetor size*** is stated in CFM (cubic feet of air per minute). This is the amount of air that can



Diaphragm spring holds secondary throttle plates closed
Diaphragm check ball
Secondary diaphragm chamber
Secondary throttle plate closed

flow through the carburetor at wide-open throttle. CFM is an indication of maximum airflow capacity.

Usually, small-CFM carburetors are more fuel efficient than larger carburetors. Air velocity, fuel mixing, and atomization is better with small throttle bores. A larger CFM rating would be desirable for high engine power output.

Variable Venturi Carburetor

A ***variable venturi carburetor*** adjusts the diameter of the venturi to maintain a relatively constant air speed in the carburetor. Many foreign cars and some American cars use this type of carburetor.

Figure 24-28 shows a variable venturi, slide-type carburetor. A piston slides in and out to regulate the size of the venturi. This type of carburetor is commonly used on motorcycles and some foreign cars.

Computer-Controlled Carburetors

A ***computer-controlled carburetor*** normally uses a solenoid-operated valve to respond to commands from a computer (control module). A typical system is shown in **Figure 24-29.**

Air-fuel mixture to engine

Figure 24-28. A slide-type, variable venturi carburetor. A cylinder-shaped slide moves in and out of the air horn to help control fuel and airflow. A conventional throttle valve is connected to the accelerator pedal.

The system uses various sensors to send information to the computer. Then, the computer calculates how rich or lean to set the carburetor's air-fuel mixture.

An ***electromechanical carburetor*** has both electrical and mechanical control devices. This type is shown in **Figure 24-30.** It is commonly used with a computer control system.

A ***mixture-control solenoid*** in the computer-controlled carburetor alters the air-fuel ratio. Electrical signals from the computer activate the solenoid to open and close air and fuel passages in the carburetor. See **Figure 24-31.**

An ***idle speed actuator*** may also be used to allow the computer to change engine idle speed. It is usually a tiny electric motor and gear mechanism that holds the carburetor throttle lever in the desired position.

Computer-Controlled Carburetor Operation

In a computer-controlled carburetor, the air-fuel ratio is maintained by cycling the mixture-control solenoid on and off several times a second. **Figure 24-32** shows how the control signals from the computer can be used to meter different amounts of fuel out of the carburetor.

When the computer sends a rich command to the solenoid, the signal voltage to the mixture-control solenoid is *off* more than it is on. This causes the solenoid to stay open more. During a lean signal from the computer, the signal has more *on* time. This causes less fuel to pass through the solenoid valve. The mixture becomes leaner.

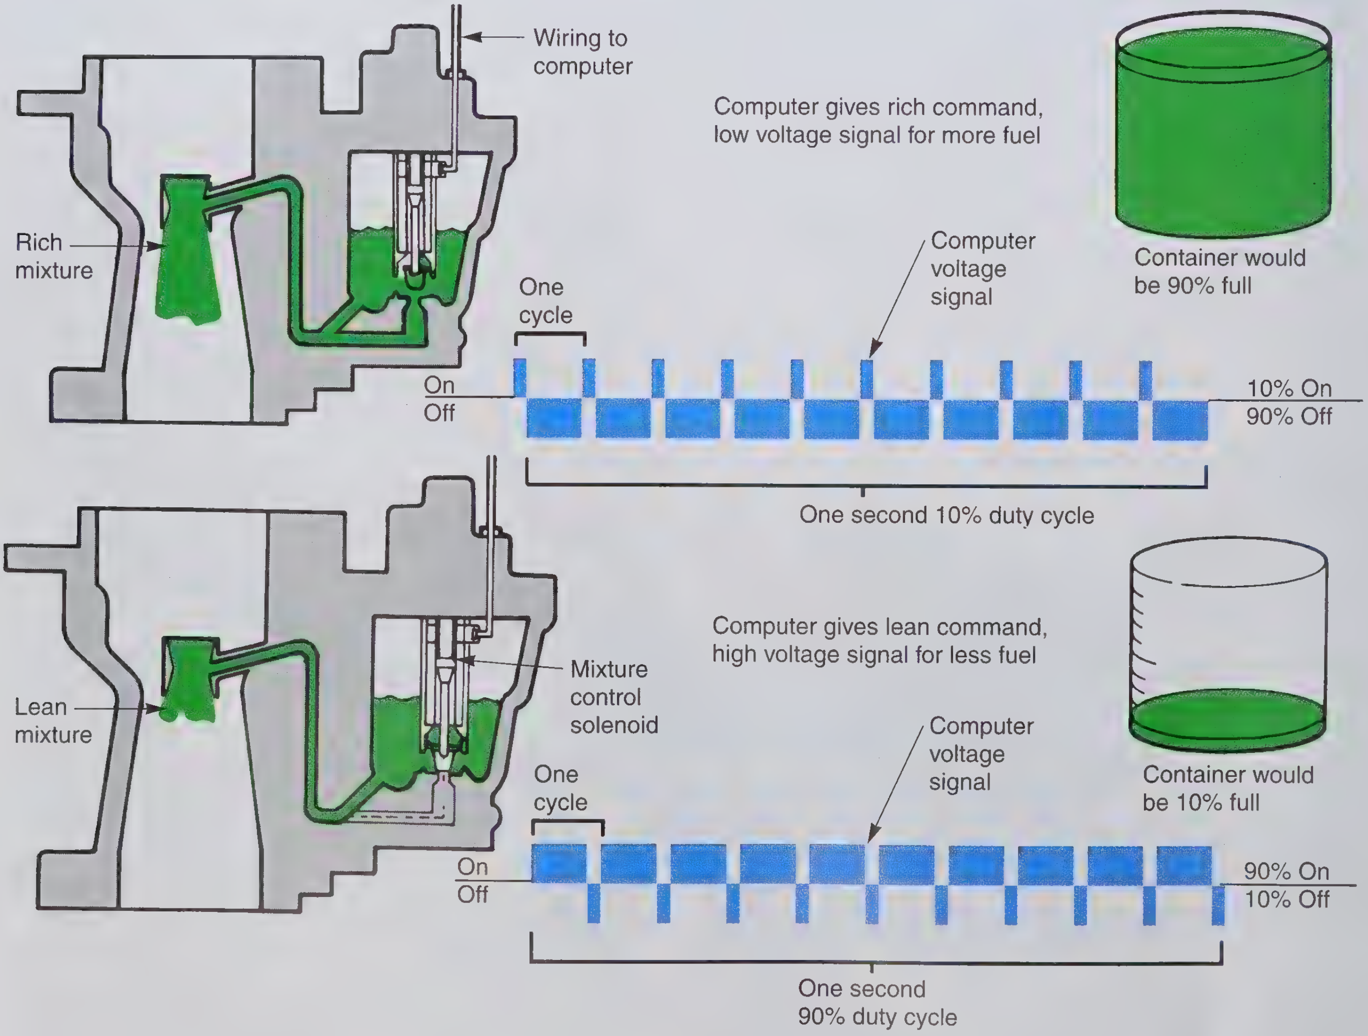
Highway History

In the 1960s people wanted speed, power, and styling in their cars. They liked big, loud, *muscle cars* with huge V-8 engines. Chrysler stuffed a 426 cubic inch Hemi Head engine, with two 4-barrel carburetors and 425 horsepower, into a small Dodge Challenger. Chevrolet "shoehorned" a 454 cubic in big block into a Chevelle. Ford stuffed a 429 Hemi into a Mustang. The Corvette had a 427 with either three two-barrel carburetors or, if even more power was desired, two four-barrel carburetors. These classic American icons are still increasing in value on the collectors' market.

Summary

- A carburetor is basically a device for mixing air and fuel n the correct proportions (amounts) for efficient combustion.



Wiring to computer
Computer gives rich command, low voltage signal for more fuel
Rich mixture
Computer voltage signal
Container would be 90% full
One cycle
On
Off
10% On
90% Off
One second 10% duty cycle
Computer gives lean command, high voltage signal for less fuel
Lean mixture

90% duty cycle

Figure 24-32. Computer rapidly pulses mixture control solenoid ON and OFF to control the air-fuel ratio. With this carburetor, note how longer OFF time enriches the mixture. Shorter OFF time makes the mixture lean. (DaimlerChrysler)

- The float system must maintain the correct level of fuel in the carburetor bowl.
- The off-idle system, often termed the part throttle circuit, feeds more fuel into the air horn when the throttle plates are partially open.
- The carburetor's high-speed system, also called main metering system, supplies the engine's air-fuel mixture at normal cruising speeds.
- The carburetor full-power system provides a means of enriching the fuel mixture for high-speed, high-power conditions.
- The choke system is designed to supply an extremely rich air-fuel ratio to aid cold engine starting.
- A computer-controlled carburetor normally uses a solenoid-operated valve to respond to commands from a microcomputer (control module).

Review Questions—Chapter 24

Please do not write in this text. Place your answers on a separate sheet of paper.

1. A carburetor is basically a device for _____ air and fuel in the correct _____ for efficient combustion.
2. List and explain the five major parts of a carburetor.
3. The air horn is the main fuel passage in the carburetor. True or False?
4. A carburetor _____ is a network of passages and related parts that controls the air-fuel ratio under specific operating conditions.
5. A venturi is used to produce vacuum in the carburetor air horn. True or False?
6. Which of the following is *not* a typical air-fuel ratio for a gasoline engine?
   (A) 8:1
   (B) 16:1
   (C) 3:1
   (D) 18:1
7. List and explain the seven major carburetor systems or circuits.
8. The carburetor _____ rides on top of the fuel to open and close the needle valve as needed.
9. A bowl vent is used to prevent a pressure or vacuum buildup in the bowl. True or False?
10. The carburetor _____ system provides the engine's air-fuel mixture at speeds below about _____ rpm or 20 mph (32 km/h).
11. What is the purpose of an idle air bleed?
12. What happens when you turn the idle mixture screw in and out?
13. Why are idle mixture screws sometimes covered with a metal plug?

14. A carburetor accelerator pump squirts fuel into the air horn when the throttle is opened for acceleration. True or False?
15. The _____ _____ carburetor system provides the leanest, most efficient air-fuel mixture at normal cruising speeds.
16. What is a high-speed jet?
17. Which of the following could *not* be included in the full-power system?
    (A) Power valve.
    (B) Metering rod.
    (C) Economizer valve.
    (D) Choke plate.
18. What is the function of a carburetor choke?
19. List and explain four types of automatic choke.
20. A mechanical choke unloader uses a metal lug on the throttle lever to physically open the choke plate at full throttle. True or False?
21. How does a vacuum choke break work?
22. What carburetor component is used to prevent dieseling?
23. Describe the difference between the primary and secondary of a carburetor.
24. How do you measure carburetor size?
25. Explain the purpose and operation of a mixture control solenoid used in a computer-controlled carburetor system.

ASE-Type Questions

1. A basic carburetor consists of each of these *except:*
    (A) venturi.
    (B) vacuum.
    (C) air horn.
    (D) fuel bowl.
2. The device that routes outside air into the engine intake manifold is called the carburetor:
    (A) barrel.
    (B) throat.
    (C) air horn.
    (D) All of the above.
3. Which of the following creates suction (vacuum) that pulls fuel from the main discharge tube?
    (A) Venturi.
    (B) Main discharge tube.
    (C) Fuel bowl.
    (D) Throttle valve.
4. For idling, carburetors must provide an air-fuel ratio of about:
    (A) 13:1.
    (B) 15:1.
    (C) 16:1.
    (D) 18:1.
5. Which of the following is *not* one of the seven basic carburetor systems?
    (A) Float.
    (B) Injection.
    (C) Full-power.
    (D) High-speed.
6. Which carburetor system provides air-fuel mixture at speeds below 20 mph?
    (A) Idle.
    (B) Choke.
    (C) Off-idle.
    (D) Acceleration.
7. The two types of accelerator pumps are the:
    (A) throttle and spring.
    (B) thermal and vacuum.
    (C) piston and diaphragm.
    (D) primary and secondary.
8. High-speed carburetor circuits consist of each of the following components *except:*
    (A) primary venturi.
    (B) air bleed.
    (C) high speed jet.
    (D) emulsion tube.
9. While figuring metering rod action, Technician A states that an engine vacuum is used to operate a metering rod. Technician B says that an electric solenoid and computer are used to operate a metering rod. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
10. Which of the following provides a variable high-speed fuel mixture?
    (A) Power valve.
    (B) Metering rod.
    (C) Economizer valve.
    (D) All of the above.

Activities—Chapter 24

1. On a carburetor of your instructor's choice, demonstrate your understanding of its systems by naming its parts and explaining their purpose.
2. Draw a simple carburetor cutaway and show how fuel and air are mixed.

25

Carburetor Diagnosis, Service, and Repair

After studying this chapter, you will be able to:

- Diagnose common carburetor problems.
- Properly remove and replace a carburetor.
- Disassemble and reassemble a carburetor while following the procedures in a service manual.
- Perform basic carburetor adjustments.
- Describe and observe all safety rules and cautions relating to carburetor service.
- Correctly answer ASE certification test questions about carburetor diagnosis and repair.

Since carbureted engines can potentially produce much more air pollution than late-model fuel-injected engines, you must be able to diagnose, service, and repair carburetors to help protect the earth's atmosphere. If a carburetor passage becomes clogged with dirt or a gasket or seal deteriorates, engine performance and emissions can suffer. Mechanical part wear of linkages and throttle shafts also affects performance and efficiency.

Carburetor Problem Diagnosis

The first step in carburetor problem diagnosis is to determine whether the carburetor or another system is at fault. Troubles in the ignition system, emission control systems, and engine can produce the same general symptoms as a faulty carburetor (missing, poor fuel economy, engine not starting).

A visual inspection of the carburetor may provide clues to the problem, **Figure 25-1.** Remove the air cleaner. Look for leaking fuel, a sticking choke, binding linkage, and missing or disconnected vacuum hoses. A heavy covering of road dirt usually indicates that the carburetor has been in service for a long time. Adjustments or repairs may be needed.

While inspecting the carburetor, check the rest of the engine compartment. Look for disconnected wires and hoses. Listen for the hissing sound of a vacuum leak. Make sure the distributor cap is not cracked. Try to locate anything that could upset normal engine operation.

Exhaust Gas Analyzer

An ***exhaust gas analyzer*** is a testing device that measures the chemical content of the engine exhaust gases. It can be used to determine the air-fuel mixture of a fuel injection system or carburetor.

The exhaust gas analyzer draws a sample of the exhaust gases (combustion byproducts) from the vehicle's tailpipe. It measures the amount of carbon monoxide (CO), hydrocarbons (HC), carbon dioxide (CO_2), oxygen (O_2), and nitrogen oxides (NO_x) in the exhaust. This information indicates combustion efficiency (how efficiently the engine is burning its fuel).

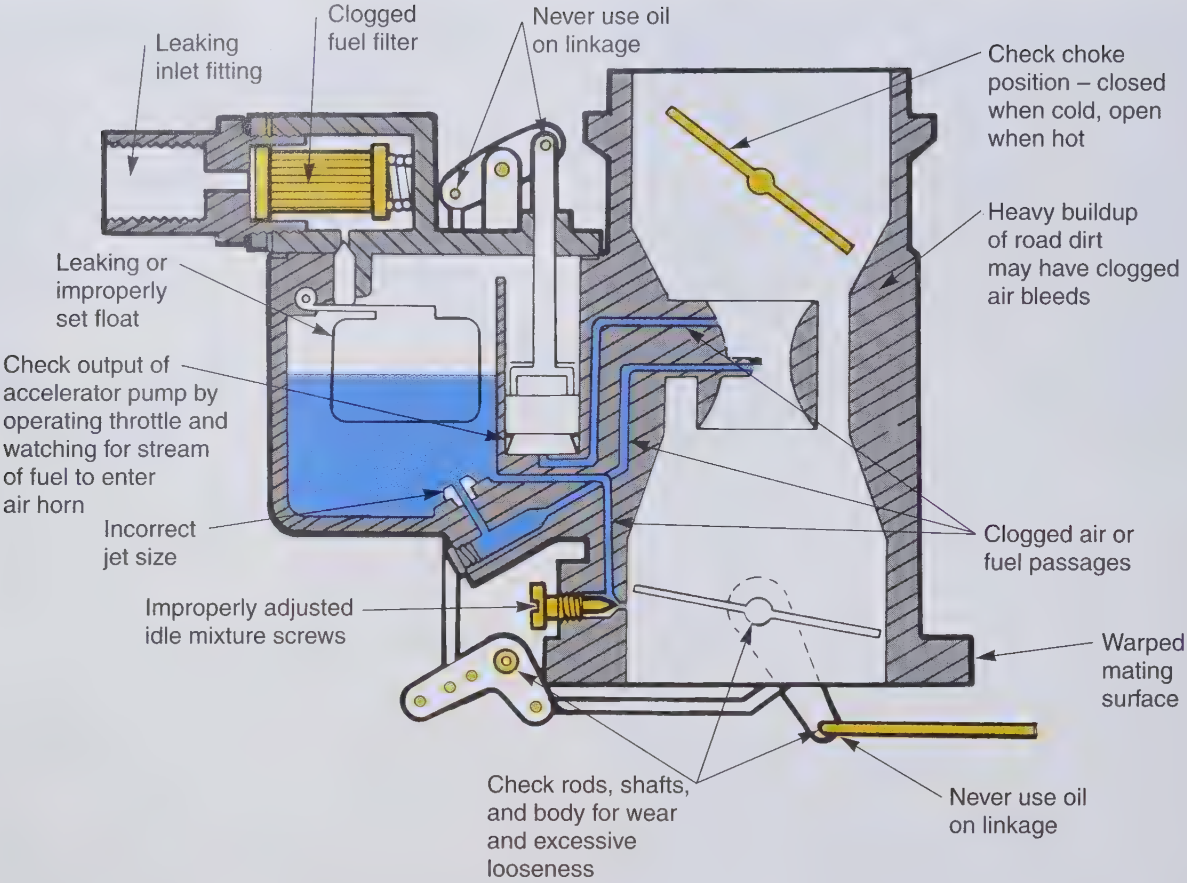
Carburetor Problems

When diagnosing carburetor problems, try to determine which system is at fault. For example, if the engine only runs poorly when cold, think of things (mechanical parts, sensors, actuators) that would be affected by cold temperatures. Check the choke and fast idle systems or the engine temperature sensor on a computer-controlled fuel system. Use this type of logic to narrow down the possible sources of problems.

Carburetor float system troubles can cause a wide range of performance problems: flooding, rich fuel mixture, lean fuel mixture, fuel starvation (no fuel), stalling, low-speed engine miss, and high-speed engine miss. See **Figure 25-2.**

Float problems can affect the operation of the engine at all speeds. The float system provides fuel for all the other carburetor circuits.

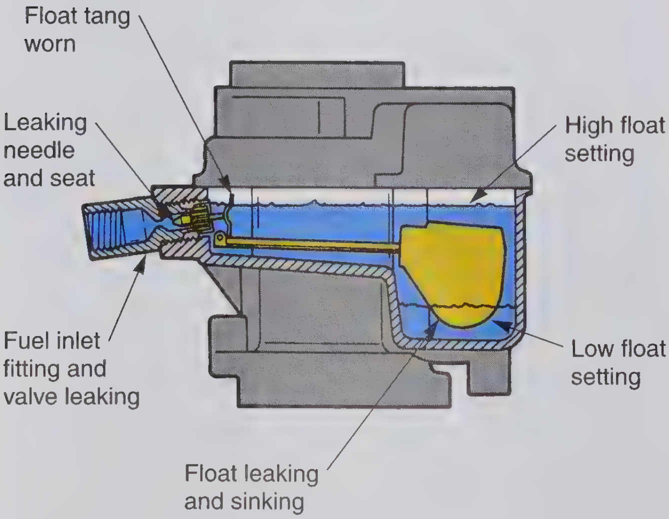
Carburetor flooding occurs when fuel pours out the top of the carburetor (vent, air bleed, or main discharge) or leaks around the bowl gasket. This problem arises



Leaking inlet fitting
Clogged fuel filter
Never use oil on linkage
Check choke position – closed when cold, open when hot
Heavy buildup of road dirt may have clogged air bleeds
Leaking or improperly set float
Check output of accelerator pump by operating throttle and watching for stream of fuel to enter air horn
Incorrect jet size
Clogged air or fuel passages
Improperly adjusted idle mixture screws
Warped mating surface
Check rods, shafts, and body for wear and excessive looseness
Never use oil on linkage

Figure 25-1. An external check of the carburetor can sometimes find the source of the problem. A few possible problems are illustrated here. (DaimlerChrysler)

when the float needle valve does not stop fuel flow from the fuel pump. The carburetor bowl overflows.



Float tang worn
Leaking needle and seat
High float setting
Fuel inlet fitting and valve leaking
Low float setting
Float leaking and sinking

Figure 25-2. Float system problems can cause flooding, fuel starvation, and poor performance at all engine speeds.

Warning!

If a carburetor floods, shut off the engine immediately. Gasoline leaking onto the intake manifold could be ignited by a spark or the hot exhaust manifold.

To correct carburetor flooding, disassemble the carburetor. Check the needle valve and seat for wear. They may need replacement. If fuel has leaked into the float, the float must be replaced. A carburetor bowl that is full of debris can also cause the needle valve to stick open. A complete carburetor overhaul is usually necessary to correct this problem.

Engine flooding is a problem resulting from too much fuel in the intake manifold and combustion chambers. Excess fuel can foul the spark plugs (fuel keeps sparks from jumping gaps), keeping the engine from running.

Engine flooding may be due to any number of reasons besides a float system problem. For example, if the driver pumps the gas pedal repeatedly, operating the accelerator pump, the engine could flood. A weak spark, stuck choke, or bad choke break diaphragm could also lead to engine flooding.

A ***high float level*** richens the air-fuel mixture. It can cause high fuel consumption, rough idling, and, possibly, black engine exhaust. To check the float setting, start the engine and let it idle. While wearing safety glasses, check for fuel dripping from the main discharge tube (venturi). If fuel leaks out the main nozzle at idle, the float setting may be too high.

A ***low float level*** can produce a lean air-fuel mixture. It can cause a high-speed miss, stalling when cornering, and other symptoms common to fuel starvation. Usually, you need to remove the air horn or bowl cover to check for a low fuel level. A few carburetors, however, have a glass inspection window or a fuel level screw on the side of the fuel bowl.

A high or low float level can usually be corrected by adjusting the float mechanism. This adjustment will be discussed later in the chapter.

Idle System Problems

Carburetor ***idle system problems*** normally show up as a rough idle, an incorrect idle speed, or stalling at low speeds. The engine may run fine at higher speeds, but poorly at idle. **Figure 25-3** points out common idle system problems.

A ***clogged idle passage*** can restrict fuel flow to the idle port. This causes a very lean mixture and poor idle. The jets in the idle circuit are very small. A tiny bit of dirt can easily upset idle circuit operation.

A ***clogged idle air bleed*** can enrich the mixture by obstructing the premixing of air, upsetting engine operation at idle. Since most of the air bleed jets are at the top of the carburetor, inspect the air bleeds and clean them, if needed.

To check for idle system problems on older cars, adjust the idle mixture screws. If turning the screws has little or no effect on idle speed and smoothness, the idle circuit is not functioning properly. The carburetor probably needs an overhaul.

Tech Tip!

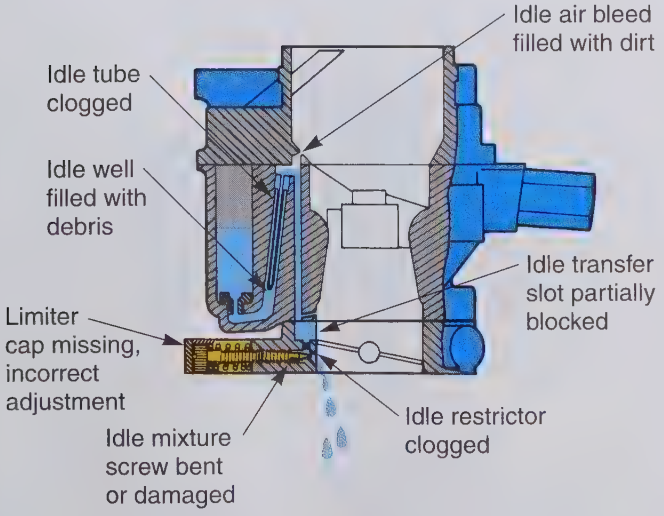
Sometimes you can clear out idle passages by revving the engine to high rpm and placing a leather glove over the carburetor air inlet. This will create a powerful suction to pull debris out of the tiny passages.

Acceleration System Problems

Carburetor ***acceleration system problems*** usually cause the engine to hesitate, stall, pop, or backfire when the car first moves. If the accelerator pump does not squirt a strong stream of fuel into the air horn as the throttles open, the mixture will be too lean for proper engine acceleration. Look at **Figure 25-4.**

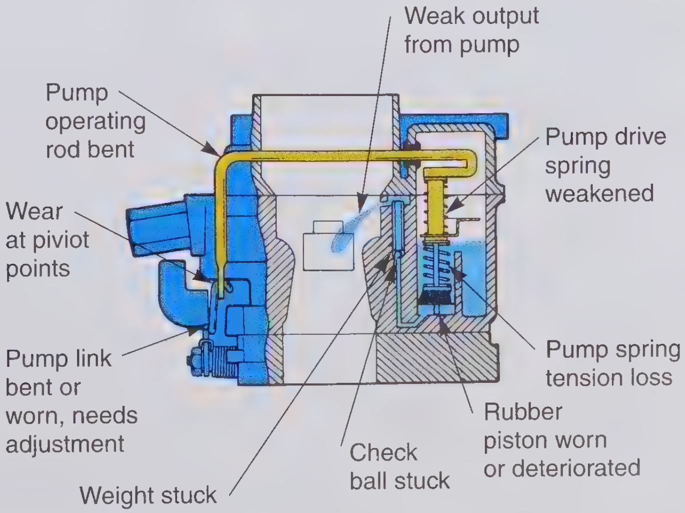
To check accelerator pump operation, shut the engine off and remove the air cleaner. Open and close the throttle while looking inside the carburetor air horn.

Each time the throttle is opened, a strong stream of fuel should spray into the air horn. The stream should start as soon as you move the throttle open. It should



Idle air bleed filled with dirt
Idle tube clogged
Idle well filled with debris
Idle transfer slot partially blocked
Limiter cap missing, incorrect adjustment
Idle restrictor clogged
Idle mixture screw bent or damaged

Figure 25-3. Idle system problems show up at very low engine speeds. Jets and passages are so small they can be clogged by tiny dirt particles. Improper adjustment of mixture screw is another common trouble. (DaimlerChrysler)



Weak output from pump
Pump operating rod bent
Pump drive spring weakened
Wear at piviot points
Pump link bent or worn, needs adjustment
Pump spring tension loss
Rubber piston worn or deteriorated
Check ball stuck
Weight stuck

Figure 25-4. A bad accelerator pump will make the engine hesitate upon acceleration. Worn or misadjusted linkage, a deteriorated pump or diaphragm, or other problems may keep fuel from squirting out of the nozzle when the throttle opens. (DaimlerChrysler)

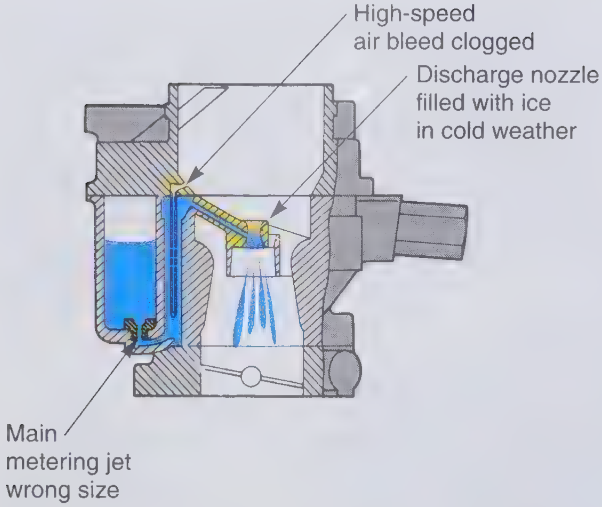


Figure 25-5. The main metering system is very simple and dependable.

continue for a short time after full throttle opening. If the stream is weak, adjust or repair the accelerator pump.

High-Speed System Problems

High-speed system problems normally show up as a lean air-fuel mixture (miss at cruising speeds) or a rich mixture (poor fuel economy). Refer to **Figure 25-5.** The high-speed system is the simplest and most dependable carburetor circuit.

Engine surge is a condition in which engine power at cruising speeds seems to alternately increase and decrease. It is frequently caused by an extremely lean air-fuel mixture. Surge is a common problem stemming from the extremely lean, high-efficiency mixtures of today's carburetors.

A ***faulty mixture control solenoid*** or computer-control circuit can upset high-speed, midrange, and low-speed carburetor operation.

Full-Power System Problems

Full-power system problems can reduce fuel economy or limit engine power in high-power situations, such as passing another car. Depending on the type of carburetor (power valve, mechanical metering rod, vacuum metering rod, or solenoid metering valve), you must use various techniques to locate and correct a full-power systems problem.

A ***bad power valve*** can allow fuel to leak into the vacuum passage. A common problem, it causes a rough idle and poor gas mileage. When the power valve diaphragm ruptures, fuel may be pulled through the diaphragm and into the air horn by vacuum. This richens the mixture. The ruptured diaphragm can also affect high-speed engine performance.

A ***faulty metering rod*** mechanism will generally upset only high-speed, high-power engine operation. If the metering rod is adjusted too far into the jet, the mixture will be too lean. If set too far out of the jet, the mixture will be too rich. A vacuum-operated metering rod can cause problems if the diaphragm ruptures or the vacuum piston sticks.

Choke System Problems

Carburetor ***choke system problems*** will usually make the engine perform poorly when cold or right after warm-up. The choke should operate only when the engine is cold. Problems usually occur during or right after starting. **Figure 25-6** shows some choke-related problems.

If the choke sticks closed, a super-rich air-fuel mixture will pour into the engine. The engine will run extremely rough, and black smoke will blow out the vehicle's tailpipe. The engine will lack power and may stall as it warms.

If the choke sticks open, the engine may not start when cold. Pumping the gas pedal several times will help. However, the engine will accelerate poorly and may stall several times after cold starting.

A slightly ***rich choke setting*** can cause the engine to run poorly after reaching operating temperature. By remaining partially closed, the choke pulls too much fuel into the engine. A slight engine miss or roll and a small amount of black exhaust smoke may result.

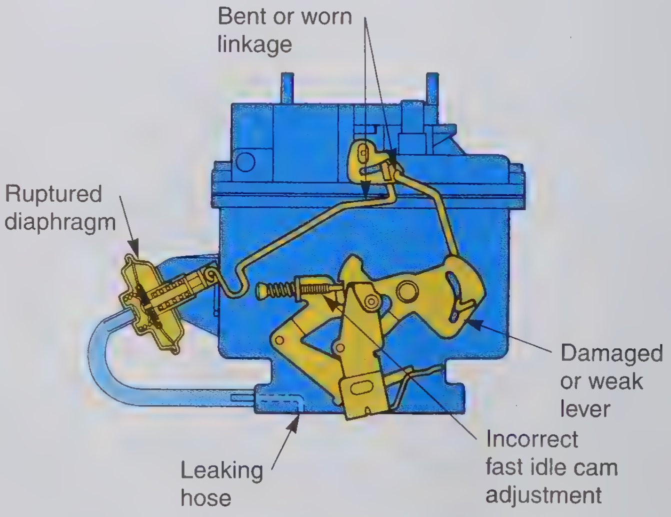

Figure 25-6. Choke malfunctions cause problems when the engine is started cold. The engine may not start easily, may stall, or may run roughly. (DaimlerChrysler)

A ***lean choke setting,*** as with an open choke, will make the engine hard to start in cold weather. No problems may be noticed in warm weather. A lean choke adjustment can cause the engine to stall when trying to accelerate with the engine cold.

Fast idle cam problems can make the engine idle too fast or too slow, usually when cold. If the fast idle is too high, a cold engine may race for extended periods. If the fast idle is too slow, a cold engine will stall right after start-up. Fast idle cam problems may stem from choke problems or an incorrect linkage adjustment.

Factory Diagnosis Charts

Use a factory or service manual ***diagnosis chart*** when you have difficulty locating a carburetor problem. Such charts are designed for each type of carburetor.

Carburetor Removal

When diagnosis points to ***internal carburetor problems*** (dirt-clogged passages, leaking gaskets or seals, worn parts), carburetor removal is usually necessary. Begin by removing the air cleaner and all wires, hoses, and linkages that would prevent removal of the carburetor.

Warning!
Wrap a shop rag around the fitting when removing a fuel line. This will keep fuel from leaking on the engine, which would create a fire hazard.

You may want to label vacuum hoses and wires that connect to the carburetor. This will simplify reassembly. See **Figure 25-7.** If the hoses and wires are not labeled before carburetor removal, you may have to trace color codes on a wiring diagram.

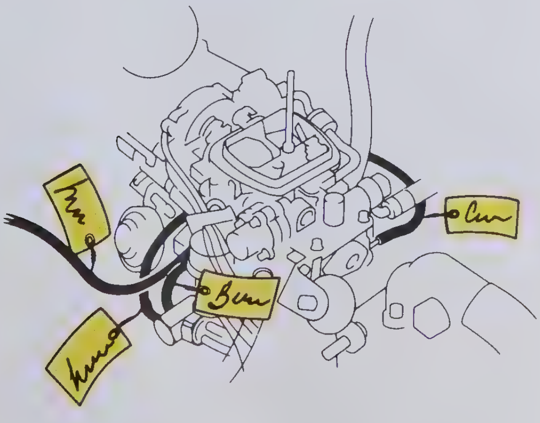

Figure 25-7. Always mark or tag wires and hoses when servicing a carburetor. This can save time and avoid confusion when reassembling. (Toyota)

Remove the four nuts or bolts that secure the carburetor to the engine intake manifold. Carefully lift the carburetor off the engine while holding it in a level position. Do not splash the fuel in the bowl around. This would stir up any dirt in the bottom of the bowl.

Tech Tip!
To prevent foreign objects from entering the intake manifold, place a shop rag or towel in the manifold's inlet opening after the carburetor has been removed. If you accidentally drop a washer or nut into the manifold, you may be doing major engine disassembly operations for free! The washer or nut can bend valves, knock holes in a piston, or score cylinder walls.

Carburetor Body Sections

Automotive carburetors are usually constructed in three sections: air horn body, main body, and throttle body, **Figure 25-8.** Sometimes, the main body and throttle body are combined into a single casting.

The ***air horn body,*** or ***upper body,*** fits on the top of the main body and serves as a lid for the fuel bowl. Shown in **Figure 25-8,** it is held on the main body with screws. A gasket fits between the main body and the air horn body. The parts that normally fasten to the air horn body are the choke, hot idle compensator, fast idle linkage rod, choke vacuum break, and, sometimes, the float and pump mechanisms.

The ***main body*** is the largest section of the carburetor. It forms the air horn and fuel bowl. Small passages are cast or drilled in this section to carry fuel and air. Usually, the main body houses the fuel bowl, main jets, air bleeds, power valve, pump checks, diaphragm-type accelerator pump, venturis, circuit passages, and float mechanism.

The ***throttle body*** is the lower section of the carburetor and contains the throttle valves. It fastens to the bottom of the main body with screws. A throttle shaft passes through the sides of the throttle body to provide a hinge for the throttle valves. A gasket between the throttle body and the main body makes the joint leakproof. The main parts found on a throttle body, besides the throttle butterflies and throttle shaft, are the throttle levers, idle mixture screws, idle speed screw, fast idle cam, dashpot, and fast idle solenoid.

Carburetor Rebuild

A ***carburetor rebuild,*** or ***overhaul,*** is needed when carburetor passages become clogged, gaskets or seals leak, rubber parts deteriorate, or components wear and fail.

A carburetor rebuild generally involves:

1. Disassembly and cleaning of major parts.
2. Inspection for wear or damage.
3. Installation of a ***carburetor rebuild kit*** (new gaskets, seals, needle valve and seat, pump diaphragm or cup, and other nonmetal parts).
4. Reassembly of the carburetor.
5. Major adjustments.

When disassembling a carburetor, follow the kit directions or the detailed directions in a service manual. Generally, remove all plastic and rubber parts. Remove any part that will prevent thorough cleaning of the carburetor passages. If not worn or damaged, the throttle plates and shaft can be left in place.

To prevent part damage, always use proper disassembly techniques. When unscrewing jets, use a special jet tool or the correct size screwdriver.

During disassembly, keep parts organized. Note the location of each part. Jet sizes are sometimes different. Therefore, jets must be reinstalled in the same location.

Carburetor cleaner, also known as ***decarbonizing cleaner,*** removes deposits. A very powerful cleaning agent, it will remove gum, carbon, oil, grease, and other deposits from inside air and fuel passages and on external parts. Place metal components in a tray and lower them into the cleaner. Allow the carburetor parts to soak for the recommended amount of time. Do not allow carburetor cleaner to contact plastic and rubber parts. The cleaner will ruin nonmetallic parts.

⚠ **Warning!**
Carburetor cleaner can cause serious chemical burns to the skin and eyes. Wear rubber gloves and eye protection when working with any chemical.

After soaking the carburetor parts, rinse them with clean water, kerosene, or cold soak cleaning solution. Dry the parts with compressed air. Force air through all passages to make sure they are clear. Do *not* use wire or a drill bit to clean out carburetor passages. This could scratch and enlarge the passages, upsetting carburetor operation.

Inspect each cleaned carburetor part carefully. Check for:

- Wear and excessive play between the throttle shaft and throttle body.
- Binding of the choke plate and linkage.
- Warpage, cracks, and other problems with carburetor bodies.
- Float leakage or a bent hinge arm.
- Nicks, burrs, and dirt on gasket mating surfaces.
- Damaged or weakened springs and stripped fasteners.
- Damage to tips of idle mixture screws.

Replace all parts that show wear or damage.

Carburetor Reassembly

To reassemble a carburetor, follow the detailed directions in the service manual. Some car makers have as many as twenty different carburetors for a single model year. This results in thousands of different reassembly procedures and adjustments. Each is critical to proper performance.

Basically, the carburetor is assembled in reverse order of disassembly. An exploded view of the carburetor, **Figure 25-9,** shows how parts fit together.

As you assemble the carburetor, several adjustments must be completed. Check a service manual for details. Adjustments typically include:

- Float drop adjustment—The float drop is the distance the float can move down in the bowl. It must be properly set to keep the float from hitting and possibly sticking to bottom. The float drop is usually set by bending a tang on the float. See **Figure 25-10.**
- Float level adjustment—Dry float level is usually set by measuring the distance from the float to the air horn cover or the top of the bowl. To change the float level, bend the other metal tang on the float. See **Figure 25-11.** Wet float level is set by checking how much fuel enters the bowl before the needle valve closes.
- Idle mixture screw "rough" adjustment—Rough adjustment of idle mixture screws typically involves bottoming screw lightly, then backing out about 2 1/2 turns, **Figure 25-12.** Final adjustment is done with the engine running.
- Choke linkage and spring adjustments—Choke adjustment is done so that the choke is almost fully closed when the engine is cold and fully open when the engine is warm. Adjustment procedures vary, so refer to the service manual for specific instructions. You may have to rotate a choke spring housing, bend linkage rods, or perform similar adjustments.
- Antistall dashpot adjustment—The throttle return dashpot is adjusted by moving the unit closer to or farther from the throttle lever. To check adjustment, depress the plunger and measure the distance between the plunger and the throttle lever with a feeler gauge. See **Figure 25-13.**
- Accelerator pump adjustment—Basically, an accelerator pump should be adjusted so that fuel squirts into the air horn as soon as the throttle is moved off idle. Adjustments are done by bending linkage rods or arms and changing rods in their holes. Refer to the service manual for details.

Carburetor Installation

To install a carburetor, place a new base plate gasket on the intake manifold. Then, fit the carburetor on the manifold. Install the fasteners that secure the carburetor to the intake manifold and torque them to specification.

Caution!
Do not overtighten the carburetor hold-down nuts or bolts. Overtightening can damage threads or warp the carburetor base plate.

Reinstall all the hoses, lines, wires, and linkages. Double-check that the vacuum hoses have been installed in their correct positions. Hand operate the throttle to make sure the throttle plates are not binding or hitting on the base plate gasket.

Figure 25-13. Adjusting the throttle return dashpot. (Ford)

To set the cold fast idle or fast idle speed, connect a tachometer to the engine. Warm the engine to operating temperature. Set the emergency brake and block the wheels of the car.

While following service manual instructions, set the fast idle cam to hold the throttle open for a fast idle. The fast idle screw must contact a specified step on the fast idle cam, **Figure 25-14.**

Turn the fast idle screw until the tachometer reads within specifications. Cold fast idle speeds vary from 750–950 rpm. Some specifications are given with the automatic transmission in drive.

Many carburetors use a solenoid to control the hot idle speed of the engine. When the engine is running, the solenoid acts on the throttle lever to hold the throttle open for the correct idle speed. Sometimes, a solenoid is used to maintain idle speed when the air conditioner is turned on. In any case, you must use factory recommendations to adjust the solenoid.

Look at **Figure 25-15.** To set hot idle speed, turn the solenoid adjusting screw until the tachometer reads correctly. Sometimes the adjustment is on the solenoid mounting bracket or on the solenoid plunger itself. Typically, hot idle speed is from about 650–850 rpm. It is lower than cold idle speed but higher than curb idle speed.

Curb Idle Speed Adjustment

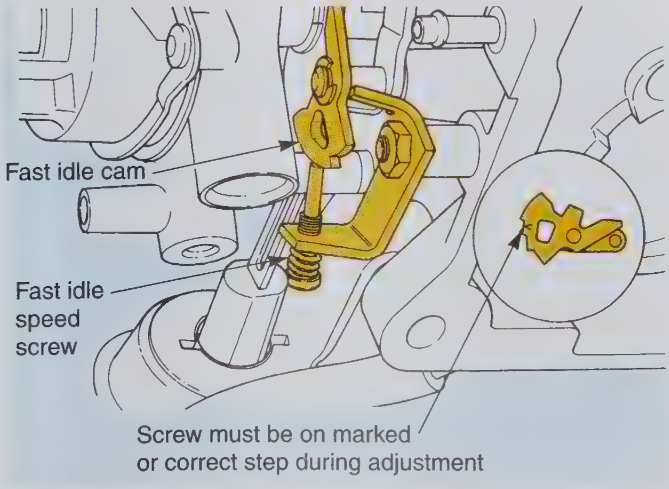
Curb idle speed is the lowest idle speed setting. On older carburetors, it is the idle speed setting that controls engine speed under normal, warm engine conditions.

However, on carburetors using a fast idle solenoid, curb idle can also be termed ***idle drop*** or ***low idle speed.*** In this case, it is a very low idle speed that only occurs as the ignition is turned off. When the solenoid is de-energized, the throttle plates drop to the curb idle setting to keep the engine from dieseling.

To adjust curb idle, disconnect the wires going to the idle speed solenoid. Then, turn the curb idle speed screw until the tachometer reads within specifications. See **Figure 25-16.** Curb idle speed is usually very low (500–750 rpm).

Idle Mixture Adjustment

After setting the idle speed, you may also need to adjust the carburetor idle mixture. There are several methods for doing this. With older, pre-emission



Fast idle cam
Fast idle speed screw
Screw must be on marked or correct step during adjustment

Figure 25-14. Fast idle speed adjustment involves turning the fast idle screw with the screw contacting the correct step on the cam. A tachometer is used to measure engine speed.

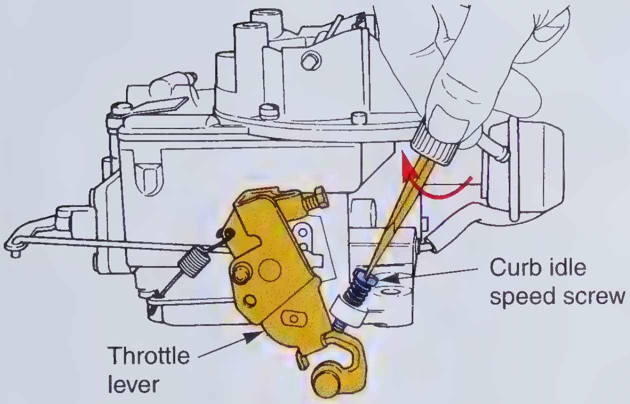
Figure 25-15. When an idle solenoid is used, energize the solenoid and adjust the engine speed to specifications by moving the solenoid or solenoid plunger. Also, note curb idle screw for lowest speed setting. (Ford)



Curb idle speed screw
Throttle lever

Figure 25-16. The curb idle speed screw simply moves the throttle when turned. Adjust to specifications using a tachometer. (Ford)

carburetors, the idle mixture screw is adjusted until the smoothest idle mixture is obtained.

To adjust idle mixture:

1. Turn the mixture screw in until the engine misses ***(lean miss).***
2. Turn the same screw out until the engine rolls ***(rich miss).***
3. Set the mixture screw halfway between the lean miss and rich roll settings.
4. Perform steps 1-3 on the other mixture screw, if needed (two- and four-barrel carburetors).
5. Recheck the idle speed. If you must reset the idle speed, then the idle mixture must be readjusted.

Propane idle mixture adjustment is required on some carburetors. A bottle of propane is connected to the air cleaner or intake manifold. The propane enriches the fuel mixture during carburetor adjustment. Following service manual procedures, you must meter a certain amount of propane into the engine while adjusting the mixture screws. This will provide a leaner setting, producing fewer exhaust emissions.

Tech Tip!

Many carburetors have sealed idle mixture screws that are preset at the factory. Unless major carburetor repairs have been made, do not tamper with these screws. To avoid a violation of federal law, follow the manufacturer's procedures for carburetor adjustments.

An ***exhaust gas analyzer*** can be used to adjust the idle mixture on some cars. The mixture screws are adjusted until the exhaust sampling is within specified limits. See **Figure 25-17.**

Figure 25-19. Some computer-controlled carburetor systems can be checked with a dwell meter. The dwell meter measures the duration of voltage pulses from computer. Dwell readings may also be used when adjusting the idle mixture. Follow the service manual directions; procedures vary for particular systems. (DaimlerChrysler)

Note!
For information on using an exhaust gas analyzer, refer to Chapter 44, *Emission Control System Testing, Service, and Repair.*

Computer-Controlled Carburetor Service

A computer-controlled carburetor system requires specialized service techniques, **Figure 25-18.** Some computer-controlled carburetor systems have a self-diagnostic, or on-board diagnostic feature. The computer will produce a trouble code that represents the possible problem source. This topic is discussed in several places in this textbook. Refer to the index as needed.

Figure 25-19 shows testing methods used on one computer-controlled carburetor system. A tachometer and a dwell meter are connected to the system. The tachometer measures engine speed. The dwell meter measures the duration of the computer's electrical signal going to the mixture-control solenoid in the carburetor. This allows the technician to determine whether the computer or the mixture-control solenoid is causing a problem.

Figure 25-20 shows the relationship between the dwell meter reading and the computer output. Note that

with this system, a high dwell signal indicates a lean command. A low dwell meter reading indicates a rich command. The computer will switch from rich (low dwell) to lean (high dwell) to maintain the correct air-fuel ratio.

Under certain operating conditions, such as wide-open throttle, the vehicle's computer may produce a fixed output. Refer to a shop manual for exact dwell specifications and test methods.

To test an older carburetor idle mixture solenoid, a hand vacuum pump is connected to the mixture solenoid. Then, the leak-down rate of the unit is measured in both the energized and de-energized positions. If leakage is not within manufacturer's specifications, the mixture control solenoid must be replaced.

Accident Report

When rebuilding the carburetor on his boss's 1965 Mustang, a poorly trained technician accidentally set the float level too high. Although the engine started fine, gasoline sprayed out of the top of the vent tube like water from a small fountain. Before the technician could shut off the engine, an ugly plume of flames rose from the engine compartment. An arcing spark plug wire ignited the gasoline.

Because of the technician's thoughtlessness, all nonmetal parts in the engine compartment were melted. Even the aluminum carburetor body was partially melted. Over $3000 worth of damage had been done to the collector car.

Summary

- Troubles in the ignition system, emission control systems, and engine can produce the same general symptoms as carburetor problems (missing, poor fuel economy, engine not starting).
- An exhaust gas analyzer is a testing device that measures the chemical content of the engine exhaust gases.
- Carburetor float system troubles can cause a wide range of performance problems: flooding, rich fuel mixture, lean fuel mixture, fuel starvation (no fuel), stalling, low-speed engine miss, and high-speed engine miss.
- Carburetor idle system problems normally show up as a rough idle, stalling at low speeds, or incorrect idle speed.
- Carburetor acceleration system problems usually cause the engine to hesitate, stall, pop, backfire, or stumble when the car first moves from a standstill.
- When diagnosis points to internal carburetor problems (dirt clogged passages, leaking gaskets or seals, worn parts), carburetor removal is usually necessary.
- Various carburetor adjustments must be made during assembly and after installation.

Review Questions—Chapter 25

Please do not write in this text. Place your answers on a separate sheet of paper.

1. The first step in diagnosis is to determine whether the _____ or _____ is at fault.
2. What should you look for when inspecting a carburetor?
3. Describe the symptoms of a lean air-fuel mixture.
4. Describe the symptoms of a rich air-fuel mixture.
5. List some causes for lean and rich air-fuel mixtures.
6. How can an exhaust gas analyzer be used when troubleshooting carburetor problems?
7. When diagnosing carburetor problems, try to determine which carburetor _____ is at fault.
8. Carburetor float system problems can cause flooding, a rich fuel mixture, a lean fuel mixture, stalling, missing, and other performance problems. True or False?

9. Define the terms "carburetor flooding" and "engine flooding."
10. A clogged idle air bleed usually tends to richen the air-fuel mixture. True or False?
11. A car tends to hesitate or lose power when accelerating from a dead stop with the engine both cold and warm. Technician A says that the choke is set too rich and that a choke adjustment may be needed. Technician B says that the accelerator pump may need adjustment or replacement because a lean mixture is indicated. Who is correct?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
12. What is engine surge?
13. List and explain the three major body sections of a carburetor.
14. Describe the five major steps for a carburetor rebuild.
15. Explain a method for testing a mixture control solenoid in a computer-controlled carburetor system.

ASE-Type Questions

1. A carburetor must adjust an air-fuel mixture as the engine's:
   (A) load changes.
   (B) speed changes.
   (C) temperature changes.
   (D) All of the above.
2. Which of these air-fuel mixtures will cause a high-speed miss?
   (A) Rich.
   (B) Lean.
   (C) Stoichiometric.
   (D) All of the above.
3. An exhaust gas analyzer measures the amount of each of these in a vehicle's exhaust *except:*
   (A) oxygen.
   (B) hydrocarbons.
   (C) helium.
   (D) carbon dioxide.
4. Which problem will *not* create a rich air-fuel mixture?
   (A) High float level.
   (B) Float system trouble.
   (C) Clogged fuel passage.
   (D) Clogged idle air bleed.
5. A faulty metering rod will generally upset:
   (A) low-speed engine operation.
   (B) high-speed engine operation.
   (C) midrange-speed engine operation.
   (D) All of the above.
6. While discussing choke system problems, Technician A states that when a choke sticks closed, black smoke blows from the car's tailpipe. Technician B says a closed choke will prevent the engine from starting when cold. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. When diagnosing problems, carburetor removal is usually necessary when there are:
   (A) worn parts.
   (B) dirt-clogged passages.
   (C) leaking gaskets or seals.
   (D) All of the above.
8. Which of the following fits on top of the main body and serves as a lid for the fuel bowl?
   (A) Air horn body.
   (B) Throttle body.
   (C) Vacuum hose.
   (D) Float assembly.
9. Each of these parts is found on a throttle body *except:*
   (A) dashpot.
   (B) butterflies.
   (C) pump lever.
   (D) fast idle solenoid.
10. To set cold idle speed, connect this to the engine:
    (A) tachometer.
    (B) dwell meter.
    (C) speed sensor.
    (D) hand vacuum pump.

Activities—Chapter 25

1. Diagnose carburetor problems from symptoms given to you by your instructor or by a customer of the automotive shop.
2. Disassemble and clean a carburetor in preparation for overhaul.
3. Determine specifications for a selected carburetor and set the float drop accurately using the appropriate measuring tool.

Carburetor Diagnosis		
Condition	**Possible Cause**	**Correction**
Flooding.	1. Defective inlet needle valve. 2. Float level too high. 3. Dirty inlet needle valve. 4. Excessive fuel pressure. 5. Float sunk. 6. Binding float. 7. Heavy fuel flow pulsations. 8. Internal circuit leakage.	1. Replace inlet needle valve and seat. 2. Adjust float level. 3. Clean needle valve, fuel lines, and filters. 4. Reduce pressure. 5. Reset float level or replace float. 6. Align float. 7. Install or replace pulsation damper. 8. Repair or replace carburetor.
Stalling and/or rough idling.	1. Idle speed too slow. 2. Inoperative throttle return dashpot. 3. Improperly adjusted throttle dashpot. 4. Improper fuel level in bowl. 5. Improperly adjusted idle mixture screw or screws. 6. Clogged idle system. 7. Inoperative or misadjusted choke. 8. Carburetor flooding. 9. Clogged air cleaner. 10. Vacuum leak. 11. Ruptured vacuum power jet diaphragm. 12. Idle mixture needles grooved. 13. Inoperative hot idle compensator (air valve). 14. Clogged bowl vent. 15. Clogged idle air bleeds. 16. Defective float needle valve. 17. Exhaust heat valve stuck open. 18. Incorrect distributor vacuum advance. 19. Restricted air cleaner and/or exhaust. 20. Secondary throttle sticking open. 21. Inoperative fast idle solenoid. 22. Contaminated fuel.	1. Increase idle speed. 2. Replace dashpot. 3. Adjust dashpot. 4. Adjust fuel level. 5. Adjust mixture screws. 6. Clean carburetor. 7. Repair or adjust choke. 8. See *Carburetor flooding.* 9. Clean or replace air cleaner. 10. Repair leak. 11. Replace power jet diaphragm. 12. Replace needles. 13. Replace air valve. 14. Open vent. 15. Clean carburetor. 16. Replace needle valve. 17. Free heat valve or replace. 18. Adjust to specifications. 19. Repair restriction or replace restricted part. 20. Free throttle. 21. Replace solenoid. 22. Flush system. Add fresh, clean fuel.
Idle speed varies.	1. Defective or improperly adjusted throttle return dashpot. 2. Loose or defective power valve. 3. Dirty throttle linkage. 4. Weak throttle return spring. 5. Sticking accelerator pedal. 6. Sticking fuel inlet valve. 7. Sticking fast idle cam. 8. Defective air cleaner vacuum motor.	1. Replace or adjust dashpot. 2. Tighten or replace power valve. 3. Clean linkage. 4. Replace with stronger spring. 5. Clean and lubricate accelerator cable and/or linkage. 6. Clean or replace valve. 7. Free cam linkage. 8. Replace motor.
Poor acceleration.	1. Disconnected accelerator pump linkage. 2. Improperly adjusted accelerator pump linkage. 3. Ruptured accelerator pump diaphragm. 4. Worn or cracked accelerator pump piston. 5. Dirty or defective accelerator pump check valve.	1. Connect linkage. 2. Adjust correctly. 3. Replace diaphragm. 4. Replace piston. 5. Clean or replace check valve.

(Continued)

Carburetor Diagnosis		
Condition	**Possible Cause**	**Correction**
Poor acceleration. *(Cont.)*	6. Clogged accelerator jets. 7. Fuel level in bowl too low. 8. Weak accelerator pump follow-through spring. 9. Exhaust manifold heat control valve stuck. 10. Inoperative power valve. 11. Clogged main fuel passage. 12. Air leaks. 13. Defective secondary diaphragm. 14. Secondary throttle plates stuck. 15. Clogged air cleaner. 16. Clogged fuel filters.	6. Clean jets. 7. Raise fuel level. 8. Replace spring. 9. Free heat control valve. 10. Clean or replace power valve. 11. Clean carburetor. 12. Repair air leaks. 13. Replace diaphragm. 14. Free throttle plates. 15. Clean or replace air filter. 16. Clean or replace filters.
Low top speed.	1. Incorrect throttle linkage adjustment. 2. Choke sticking on. 3. Low or high float level. 4. Air leak. 5. Inoperative secondary throttle valves. 6. Improper secondary throttle adjustment. 7. Main jet too small. 8. Main jet clogged. 9. Obstruction under accelerator pedal.	1. Adjust linkage correctly. 2. Clean and adjust choke. 3. Adjust float level. 4. Repair air leak. 5. Clean and rebuild carburetor. 6. Adjust throttle correctly. 7. Install proper size jet. 8. Clean carburetor. 9. Remove obstruction.
Hard starting when cold.	1. Inoperative or improperly adjusted choke. 2. Flooding from excessive use of accelerator pump or rich choke. 3. Failure to depress throttle to allow choke valve to close. 4. Air leak. 5. Incorrect fuel level in bowl. 6. Clogged bowl vent. 7. No fuel delivery. 8. Stale or contaminated fuel. 9. Gasoline not sufficiently volatile. 10. Vacuum leaks.	1. Clean and adjust choke. 2. Hold throttle in wide open position and crank engine. Advise driver. 3. Advise driver. 4. Repair air leak. 5. Adjust fuel level. 6. Clean bowl vent. 7. Check tank and delivery system. 8. Drain tank. Flush system. Fill with fresh fuel. 9. Change to more volatile fuel. 10. Locate and repair.
Hard starting when hot.	1. Flooding from excessive use of choke or accelerator pump. 2. Vapor lock. 3. Clogged bowl vent. 4. Air leak. 5. Clogged air cleaner. 6. Fuel level incorrect. 7. No fuel delivery. 8. Stale or contaminated fuel. 9. Improper choke unloader adjustment. 10. Vacuum hoses split, kinked, or loose. 11. Fuel vapor boil over. 12. Overheated carburetor.	1. Hold throttle wide open and crank until engine starts. 2. Cool lines. Change to less volatile fuel and protect lines from heat. 3. Clean bowl vent. 4. Repair air leak. 5. Clean or replace air filter. 6. Adjust fuel level. 7. Check delivery system. 8. Drain fuel system. Fill with fresh fuel. 9. Adjust properly. 10. Replace and secure connections. 11. Hold throttle full open while cranking. 12. Check for proper heat shield and/or insulator installation.

26

Diesel Injection Fundamentals

After studying this chapter, you will be able to:

- Explain the operating principles of a diesel injection system.
- Summarize the differences between gasoline and diesel engines.
- Describe the major parts of a diesel injection system.
- Compare variations in the design of diesel injection systems.
- Correctly answer ASE certification test questions that require a knowledge of the fundamentals of diesel injection.

A ***diesel fuel injection*** system is a primarily high-pressure, mechanical system that delivers fuel directly into the engine combustion chambers. It is unlike a lower-pressure, gasoline system, which meters fuel into the engine intake manifold. Diesel fuel injection is relatively simple. It uses a mechanical, high-pressure pump with electronic controls.

Note!
Several earlier chapters discuss information essential to this chapter. If needed, use the index to locate and review coverage of diesel engines, diesel fuel, fuel pumps, fuel filters, compression ratios, and diesel combustion. Diesel engines are quite different from gasoline engines.

Diesel and Gasoline Engine Differences

Before covering the parts of a diesel injection system in detail, you should review the major differences between a gasoline engine and a diesel engine. This will help you understand diesel injection.

- Diesel engines use a very high compression ratio (approximately 17:1 to 25:1). A gasoline engine's compression ratio is only 8:1 or 10:1.
- A diesel engine is a compression ignition engine because it uses the heat from compressed air to ignite the fuel. Gasoline engines are classified as spark ignition engines because they use an electric arc (from the spark plug) to ignite the fuel.
- A diesel engine has no throttle valve to control airflow into the engine. Gasoline engines use a throttle valve to control airflow and engine power. Diesel engines use an injection pump to control engine power output.
- A diesel engine compresses air on its compression stroke. A gasoline engine compresses an air-fuel mixture.
- A diesel engine injects fuel directly into the combustion chambers. A gasoline engine meters fuel into the intake manifold.
- In a diesel engine, speed and power are controlled by the amount of fuel injected into the engine. More fuel produces more power. A gasoline engine controls engine power by regulating air and fuel flow with a throttle valve.

Basic Diesel Injection System

Refer to **Figure 26-1,** which shows a basic diesel injection system.

- ***Injection pump***—high-pressure, mechanical pump that meters the correct amount of fuel and delivers it to each injector nozzle at the proper time.
- ***Injection lines***—high-strength steel tubing that carries fuel to each injector nozzle.
- ***Injector nozzles***—spring-loaded valves that spray fuel into each combustion chamber.
- ***Glow plugs***—electric heating elements that warm air in precombustion chambers to aid starting of cold engine.

Figure 26-1. Basic parts of a simplified diesel injection system. The injection pump plunger produces very high pressure to open injector valve. A glow plug warms the air in the precombustion chamber when the engine is cold.

The *diesel fuel supply system* feeds fuel to the injection pump, normally using an inline electric pump, **Figure 26-2.** The engine-driven injection pump then controls how much fuel is forced to the injector nozzles. The high-pressure injection lines carry fuel to the injectors. The spring-loaded nozzles are normally closed. However, when the injection pump produces enough pressure, each nozzle opens and squirts a fuel charge into the engine *cylinders* to start combustion. A return line carries excess fuel back to the tank.

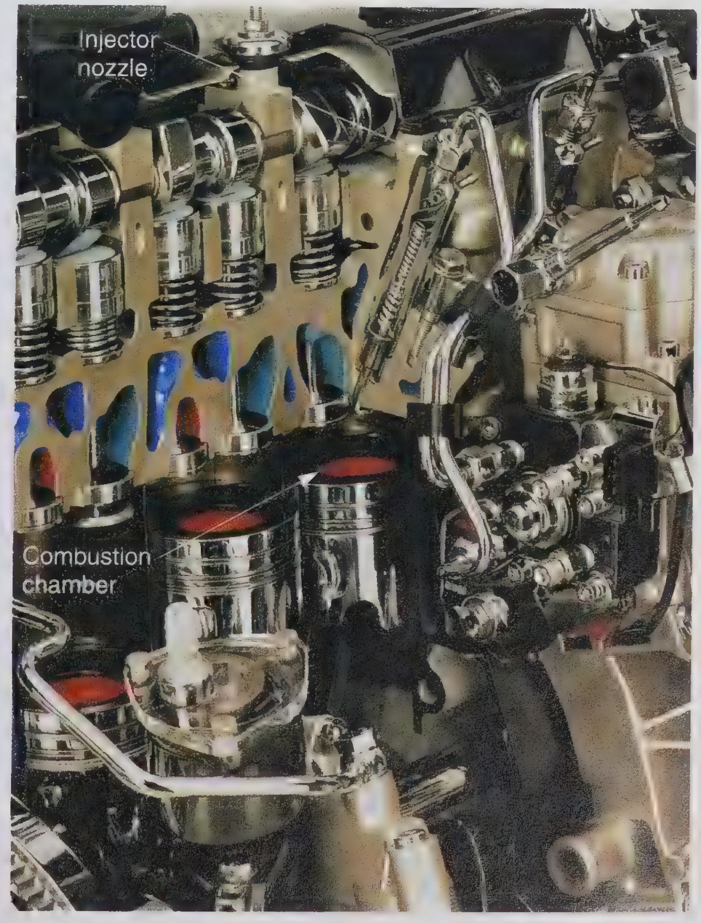
Figure 26-2. Schematic of complete diesel fuel injection system. The lift pump feeds fuel into the injection pump. The injection pump produces high pressure for injection into combustion chambers. (Ford)

Diesel Injection Pumps

A diesel injection pump has several important functions:

- Meters the correct amount of fuel to each injector.
- Circulates fuel through fuel lines and nozzles.
- Produces extremely high fuel pressure.
- Times fuel injection to meet the speed and load of the engine.
- Provides a means for the driver to control engine power output.
- Controls engine idle speed and maximum engine speed.
- Helps close injector nozzles after injection.
- Provides a means of shutting off the engine.

The diesel injection pump is normally bolted to the side or top of the engine. See **Figure 26-3.** The fuel supply system (fuel tank, lines, filters, conventional fuel pump) pushes clean, filtered fuel under low pressure to the injection pump.



Injector nozzle
Combustion chamber

Figure 26-3. This diesel has an injection pump on top of the engine, at upper right of photo. Can you find it? Study other parts. (Audi)

The injection pump then pressurizes the fuel. A camshaft acts on a plunger. The plunger slides up in its barrel (cylinder), compressing and pressurizing the fuel. The fuel then flows through the injection line and out the injector nozzle.

A diesel injection pump is powered by the engine. Power may be transferred by a set of gears, a chain, or a toothed belt. There are two common types of automotive diesel injection pumps: inline pumps and distributor pumps.

Inline Diesel Injection Pumps

An ***inline diesel injection pump*** has one plunger (piston) for each engine cylinder. The plungers are lined up in a row, like the pistons in an inline engine.

The major parts of an inline injection pump are shown in **Figures 26-4** and **26-5.** Refer to these illustrations as the parts are introduced.

The inline ***injection pump camshaft*** operates the plungers. It has lobes like an engine camshaft. When the engine turns the pump camshaft, the lobes push on the roller tappets to move them up and down.

The ***injection pump roller tappets*** transfer camshaft action to the plungers. Like roller lifters in an engine, the roller tappets reduce friction and wear on the cam lobes.

Plunger
Barrel
Delivery valve
AMERICAN BOSCH
Control rack
Roller tappet
Governor assembly
Camshaft
Transfer pump

Figure 26-4. Cutaway shows basic parts of an inline diesel injection pump. (Robert Bosch)

Inline pump plungers are small pistons that push on and pressurize the diesel fuel. When the cam lobe acts on the roller tappet, both the tappet and the plunger are pushed upward.

The ***barrels*** are small cylinders that hold the plungers. When the plunger slides upward in its barrel, extremely high fuel pressure is formed.

The ***plunger return springs*** keep a downward pressure on the plungers and roller tappets. This holds the tappets against the camshaft when the lobes rotate away from the rollers.

Control sleeves alter the amount of fuel pushed to each injector nozzle. See **Figure 26-6** and locate the control sleeve.

A ***control rod,*** or ***rack,*** is a toothed shaft that acts as a throttle to control diesel engine speed and power. It rotates the control sleeves to increase or decrease injection pump output and engine power.

Delivery valves are spring-loaded valves in the outlet fittings to the injection lines. They help ensure quick, leak-free closing of the injector nozzles.

Inline Injection Pump Operation

When the engine is running, the injection pump camshaft rotates at one-half engine speed. When the cam lobe is not pushing on the roller tappet, the lift pump (fuel supply pump) fills the barrel with fuel. Then, as the cam lobe puts pressure on the roller tappet, the plunger is forced upward in its barrel. This forces fuel through the delivery valve, through the injection line, out of the nozzle, and into the engine. See **Figure 26-7.**

As the plunger reaches the end of its stroke, pressure drops and the delivery valve closes. The delivery valve action helps reduce injection line pressure rapidly, keeping fuel from dripping from the injector nozzle.

When the cam lobe moves away from the roller tappet, the plunger return spring pushes the plunger down. Fuel can again fill the barrel. This readies the plunger to supply fuel for another power stroke.

Inline Injection Pump Fuel Metering

To control the amount of fuel injected into the engine, the control rod (or rack) slides across the control sleeves to rotate them. Look at **Figure 26-8.**

Figure 26-8. The control rack is linked to the gas pedal and governor. Two forces work together to control the rack position and amount of fuel injected. (DaimlerChrysler)

A helix-shaped (spiral) groove and a slot are cut into the side of the plunger. When the helix is aligned with the port (hole) in the side of the barrel, the plunger cannot develop pressure. Fuel will flow down the slot, through the helix groove, and out of the port.

The ***effective plunger stroke*** is the amount of plunger movement that pressurizes the fuel. It controls the amount of fuel delivered to the injectors.

When the plunger moves up and the helix is not aligned with the barrel port, fuel is trapped and

pressurized. In this way, rotation of the sleeve can be used to regulate how much fuel is injected into the engine's combustion chambers.

Inline Injection Pump Governor

A ***governor*** is used on an inline injection pump to control engine idle speed and limit maximum engine speed. Look at **Figure 26-9.** A diesel engine can be damaged if allowed to run too fast. **Figure 26-10** shows a cutaway view of an inline injection pump governor.

Notice how the governor uses ***centrifugal*** (spinning) weights, springs, and levers, **Figure 26-11.** The levers are connected to the control rack. If engine speed increases too much, the governor weights are thrown outward. This moves the levers and control rack to reduce the effective stroke of the plungers. Engine speed is limited.

When the driver presses the accelerator pedal for more power, the accelerator linkage moves a throttle lever on the side of the injection pump governor. See **Figure 26-12.** This causes throttle lever spring pressure to overcome governor spring pressure. The control rack is moved to increase fuel delivery and engine power. Only when engine speed reaches a preset level does the governor overcome the full-throttle lever position.

Injection Timing

Injection timing refers to when fuel is injected into the combustion chambers in relation to the engine's piston position. It is similar to spark timing in a gasoline engine.

Injection timing in an inline injection pump is usually controlled by spring-loaded weights. As engine speed increases, the weights fly outward to advance injection timing. This gives the diesel fuel more time to ignite and burn properly.

Inline Injection Pump Fuel Flow

Look at **Figure 26-13.** It illustrates the flow of fuel through a diesel injection system using an inline pump. Note how return fuel lines are provided. This allows a steady flow of excess fuel through the system to help cool and lubricate moving parts.

Distributor Injection Pumps

A ***distributor injection pump*** normally uses only one or two plungers to supply fuel for all of the engine's cylinders. It is the most common type of pump used on passenger cars, **Figure 26-14.**

In many ways, the operation of a distributor pump is similar to the action of an inline injection pump. Both use small plungers to trap and pressurize fuel. Both align and misalign fuel ports to control fuel flow to the injector nozzles. Both use delivery valves, governors, and other similar parts.

Figure 26-14. Single-plunger distributor diesel injection pump. Study the part names. (DaimlerChrysler)

There are two common variations of the distributor injection pump: single-plunger and two-plunger. Both will be discussed.

Single-Plunger Distributor Injection Pump

The major parts of a single-plunger distributor injection pump are shown in **Figures 26-15** and **26-16.** Refer to these illustrations as the parts are discussed.

The ***drive shaft*** uses engine power to operate the parts in the injection pump. The outer end of the shaft holds either a gear, chain sprocket, or a belt sprocket. This provides a drive mechanism for the pump.

A ***transfer pump*** is a small pump that forces diesel fuel into the injection pump. This lubricates the pump and fills the pumping chambers. Most transfer pumps for distributor pumps are vane-type pumps.

A ***distributor plunger*** is a small piston that produces high fuel pressure. It is comparable to an inline plunger.

A ***cam plate*** is a rotating lobed disc that operates the plunger. Like an inline pump camshaft, the cam plate forces the plunger to move and develop injection pressure.

A ***fuel metering sleeve*** can be slid sideways on the plunger to change the effective plunger stroke (plunger movement that causes fuel pressure). It surrounds the plunger. The fuel metering sleeve performs the same function as the sleeves and control rack in an inline pump. The sleeve controls injection quantity, engine speed, and power output.

The ***hydraulic head*** is the housing around the plunger. It contains passages for filling the plunger barrel with fuel and for injecting fuel into the delivery valves.

A ***centrifugal governor*** helps control the amount of fuel injected and engine speed. Flyweight action moves the metering sleeve to limit top speed.

Single-Plunger Distributor Pump Operation. As the injection pump shaft rotates, the fill port in the hydraulic head lines up with the port in the plunger. At this point, the transfer pump can force fuel into the high-pressure chamber in front of the plunger. Refer to **Figure 26-17.**

With more shaft and plunger rotation, the fill port moves out of alignment and an injection port lines up. At this instant, the cam plate lobe pushes the plunger sideways. Fuel is forced out of the injection port to the correct injector nozzle.

This process is repeated several times during each rotation of the injection pump drive shaft. Fuel injection must be timed to occur at each nozzle as that engine piston nears TDC (top dead center) on its compression stroke.

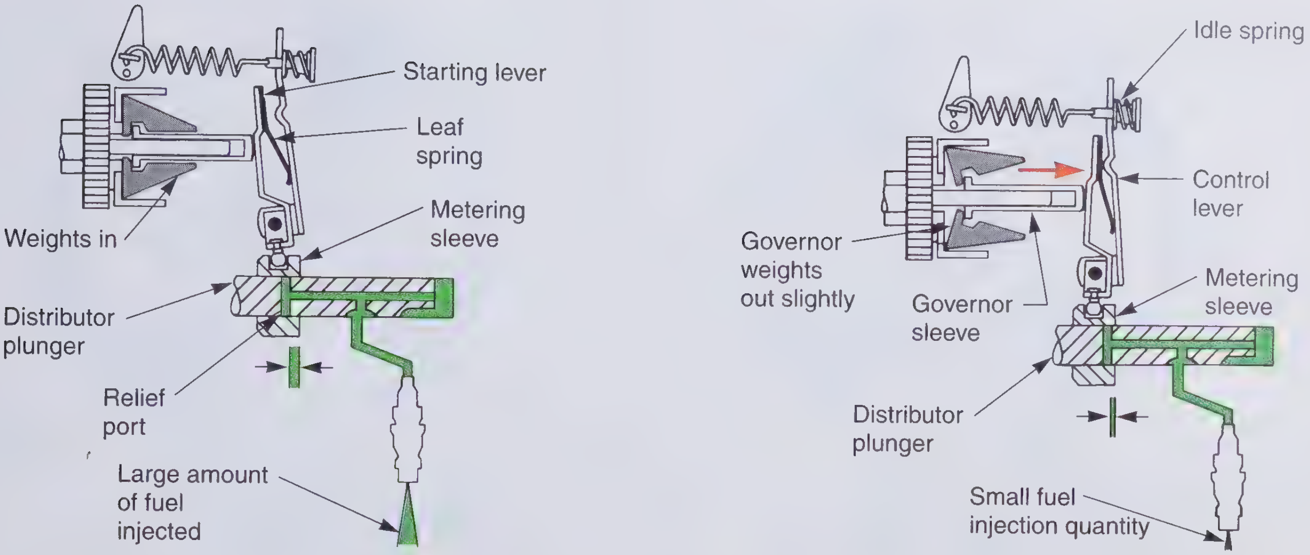
Single-Plunger Distributor Pump Fuel Metering. In a single-plunger distributor injection pump, the amount of fuel injected is controlled by movement of the metering sleeve on the plunger. The sleeve slides one way to increase fuel delivery by covering the spill port (relief port). The sleeve moves the other way to reduce delivery by uncovering the spill port. This allows the fuel to flow into the return line.



Starting lever

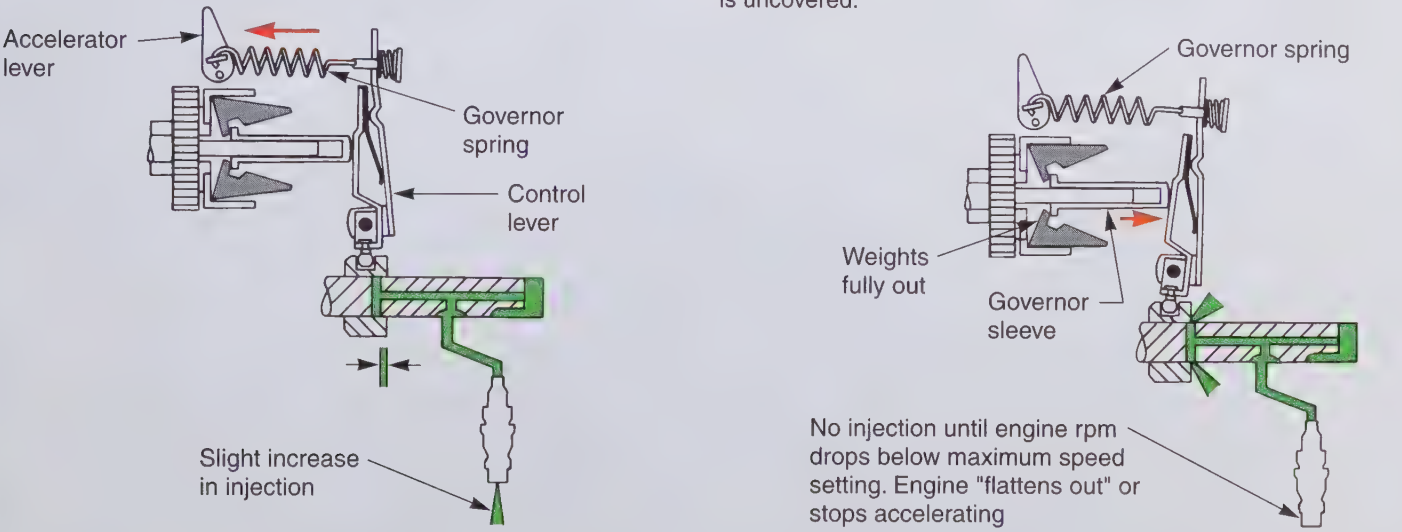
Large amount of fuel injected
Idle spring
Control lever
Governor weights out slightly
Governor sleeve
Metering sleeve
Distributor plunger
Small fuel injection quantity

Starting—Leaf spring presses starting lever to left so metering sleeve moves to right. Distributor plunger moves farther before relief port is exposed. Injection lasts longer.

Idle—Weights in centrifugal governor are partly expanded so governor sleeve moves to right. Metering sleeve moves to left. Distributor plunger now moves a short distance before relief port is uncovered.



Accelerator lever
Governor spring
Control lever
Slight increase in injection
Governor spring
Weights fully out
Governor sleeve
No injection until engine rpm drops below maximum speed setting. Engine "flattens out" or stops accelerating

Acceleration—Control lever is pulled to left by linkage from accelerator pedal. Metering sleeve is moved to right. Engine speed increases until governor "neutralizes" effect of pedal linkage.

Maximum speed—Governor is spinning with enough centrifugal force for governor sleeve to stretch governor spring. Metering sleeve uncovers relief port at beginning of distributor plunger stroke.

Figure 26-17. These illustrations show the basic operation of a single-plunger distributor diesel injection pump.

Single-Plunger Distributor Pump Injection Timing. At the end of the engine compression stroke, diesel fuel must be injected directly into the precombustion chamber. Injection must continue past TDC to make sure all of the fuel burns and adequate power is developed.

As engine speed increases, injection must occur sooner to ensure peak combustion pressure right after TDC. Increased engine speed causes the transfer (vane) pump to spin faster. This increases the pressure output of the transfer pump. The pressure is used to move an injection advance piston. The piston, in turn, causes the cam plate ramps (lobes) to engage the plunger sooner, advancing the injection timing. Look at **Figure 26-18.**

Two-Plunger Distributor Pump

A two-plunger distributor injection pump is pictured in **Figure 26-19.** Besides many of the basic parts already covered, this injection pump consists of:

- ***Two plungers***—two small pistons that move in and out to force fuel to each injector nozzle.
- ***Distributor rotor***—slotted shaft that controls fuel flow to each injector nozzle.

- ***Internal cam ring***—lobed collar that acts as a cam to force plungers inward for injection of more fuel.
- ***Fuel metering valve***—rotary valve that regulates fuel injection quantity by controlling how far the two plungers move apart on the pump's fill stroke.

The other parts of a two-plunger distributor pump (transfer pump, hydraulic head, delivery valve) are almost the same as those found in a single-plunger pump. **Figure 26-20** gives a circuit diagram for a two-plunger distributor pump. Study this illustration carefully.

Two-Plunger Distributor Pump Operation. When the engine is running, the drive shaft turns the transfer (vane) pump. This pulls fuel into the injection pump. When the charging ports line up, fuel fills the high-pressure pumping chamber.

As the shaft continues to turn, the charging ports move out of alignment and the discharge ports line up. At this instant, the plungers are forced inward by the cam ring. This pressurizes the fuel and pushes it out of the hydraulic head to the injector nozzles. Look at **Figure 26-19** to locate the plungers.

Other Diesel Injection Pump Features

There are numerous design variations of injection pumps. For details of each pump design, refer to the pump manufacturer's service manual. It will explain the construction and operation of the particular pump.

A few additional features that many automotive diesel injection pumps have include:

- ***Electric fuel shutoff***—a solenoid that stops fuel injection when the ignition key is turned off. See **Figure 26-19.**
- ***Viscosity compensating valve***—this allows for different fuel weights or thicknesses and temperatures.
- ***Injection pump vent***—a small passage that allows fuel to return to the fuel tank. This helps bleed air out of the system, **Figure 26-20.**

Diesel Injector Nozzles

Diesel injector nozzles are spring-loaded valves that spray fuel directly into the engine precombustion chambers. See **Figure 26-21.**

The injector nozzles are threaded into the cylinder head. One injector is provided for each cylinder. The inner tip of the injector nozzle is exposed to the heat of combustion, like a spark plug in a gasoline engine.

Nozzle

Figure 26-22. Basic diesel injector construction. Note the part names, shapes, and locations. (Robert Bosch)

A ***diesel injector heat shield*** helps protect the injector from engine heat. It also helps make a good seal between the injector and the cylinder head.

The ***injector body*** is the main section of the injector, which holds the other parts. The body threads into the heat shield. The heat shield threads into the cylinder head. Fuel passages are provided in the injector body. A needle seat is formed by the lower opening in the injector body.

The ***diesel injector needle valve*** opens and closes the nozzle (fuel opening). It is a precisely machined rod with a specially shaped tip. When the needle valve is closed, its tip seals against the needle seat in the injector body.

The ***injector spring*** holds the injector needle valve in the normally closed position. It fits around the needle valve and against the injector body. Spring tension helps control injector opening pressure.

An ***injector pressure chamber*** is formed around the tip of the injector needle valve and inner cavity in the injector body. Injection pump pressure forces fuel into this chamber to push the needle valve open.

Diesel Injector Nozzle Operation

When the injection pump produces high pressure, fuel flows through the injection line and into the inlet of the injector nozzle. Look at **Figure 26-23.** Fuel then flows down through the fuel passage in the injector body and into the pressure chamber.

The high fuel pressure in the pressure chamber forces the needle valve upward, compressing the injector spring. This allows diesel fuel to spray out, forming a cone-shaped spray pattern. Some fuel leaks past the injector needle valve and returns to the fuel tank through the return lines.

Diesel Injector Nozzle Types

Several types of injector nozzles are used in diesel engines, **Figure 26-24.** Most automotive diesels use an inward opening, pintle injector nozzle. **Figure 26-25** shows some typical spray patterns.

Glow Plugs

Glow plugs are heating elements that warm the air in precombustion chambers to help start a cold diesel engine. Refer to **Figure 26-26** and **Figure 26-27.**

The glow plugs are threaded into holes in the cylinder head. The inner tip of the glow plug extends into the precombustion chamber.

Glow Plug Control Circuit

A ***glow plug control circuit*** automatically disconnects the glow plugs after a few seconds of operation. **Figure 26-28** shows a typical glow plug circuit.

The ***engine coolant temperature sensor*** checks the temperature of the engine coolant. It feeds this electrical data to a control unit. Thus, if the engine is already warm, the control unit will not turn on the glow plugs.

Indicator lights, also operated by the control unit, inform the driver whether or not the engine is ready to start. The glow plugs need only a few seconds to heat up.

Battery

Figure 26-28. Basic circuit for glow plugs. The control unit monitors engine temperature and informs the driver when glow plugs have been activated long enough for the engine to start. (DaimlerChrysler)

Glow Plug Operation

When the engine is cold and the driver turns the ignition switch to run, a large current flows from the battery to the glow plugs. In a few seconds, the glow plug tips will heat to a dull red glow.

When the glow plug indicator light goes out, the driver can start the engine. The compression stroke pressure and heat, along with the heat from the glow plugs, help the engine start easier.

Diesel Injection System Accessories

Various diesel injection system accessories are used to aid in the dependability of a diesel engine. These accessories are needed because diesel fuel is susceptible to problems caused by moisture and low temperatures.

Water Detector

A ***water detector*** may be used to warn the driver of water in the diesel fuel. Such contamination is very harmful to a diesel fuel system. The water mixes with the fuel and can cause corrosion of the precision parts in the injection pump and injectors. **Figure 26-29** shows a circuit using an in-tank water detector.

Fuel Heater

A ***fuel heater*** is sometimes used to warm the diesel fuel, preventing the fuel from jelling (turning into a semisolid). An optional device, it is needed in very cold climates. The heater is simply an electric heating element in the fuel line ahead of the injection pump. See **Figures 26-29** and **26-30.**

The fuel heater warms the fuel in the line before it enters injection pump. Heat is only needed in cold weather. (General Motors)

Block Heater

A ***block heater*** may be used to warm the engine block in cold weather. It is a heating device that plugs into a home wall electric outlet. It keeps the engine warm overnight to make the diesel engine easier to start on cold mornings.

Vacuum Pump

A ***vacuum pump*** is frequently used on a diesel engine to provide a source of vacuum (suction) for the vehicle. Vacuum is needed for the power brakes, A/C ventilation system, and emission control devices.

A gasoline engine has a natural source of vacuum in the intake manifold. A diesel engine has very little vacuum in the intake manifold because it does not have a throttle valve restriction. For this reason, a vacuum pump is needed.

A vacuum pump on a diesel engine may be a reciprocating diaphragm-type pump bolted to the front or rear of the engine, **Figure 26-31.** It may also be a rotary-type pump at the rear of the alternator, **Figure 26-32.**

A vacuum pump uses the same principle as a fuel pump (see Chapter 21). However, it pumps air, not liquid fuel, out of an enclosed area to reduce pressure and form a vacuum. The diesel engine provides power for the vacuum pump, usually through a belt.

Computer-Controlled Diesel System

A ***computer-controlled diesel system*** uses a computer, sensors, and actuators to increase the efficiency of mechanical diesel injection. A simplified illustration is given in **Figure 26-33.**

In the past, diesel injection was totally mechanical. All of the controls for the system were linkages, levers, rods, and gears. Mechanical controls were heavy and slow to react. Electronic components have been designed to replace many mechanical devices and improve efficiency.

Injection pump solenoids can be used to control injection timing and injection quantity. They react to signals from the computer. When energized or de-energized electrically, they can open or block fuel passages to alter pump operation.

Diesel injection sensors are used to monitor engine temperature, speed, and other variables that affect fuel needs. The sensors feeds signals to the computer. These sensors are similar to those used for gasoline injection.

The ***diesel injection computer*** monitors sensor inputs and calculates the outputs for the actuators. In this way, the computer can more precisely control the mechanical, high-pressure plungers inside the diesel injection pump.

Accident Report

An older diesel-powered car (with a mechanical fuel pump but without computer control) was brought into the shop for service. As the technician was working on the vehicle, the rack in the injection pump broke in the wide-open position. The engine raced to maximum speed. Unfortunately, the fuel cutoff solenoid in the injection pump had also failed and was stuck open.

With the fuel cutoff solenoid not working, turning the ignition key off had no effect. The technician had to break the fuel line between the fuel tank and the supply pump in order to stop the flow of fuel.

This is a rare occurrence. However, it shows how two simultaneous problems can cause strange results. Keep this in mind when troubleshooting problems.

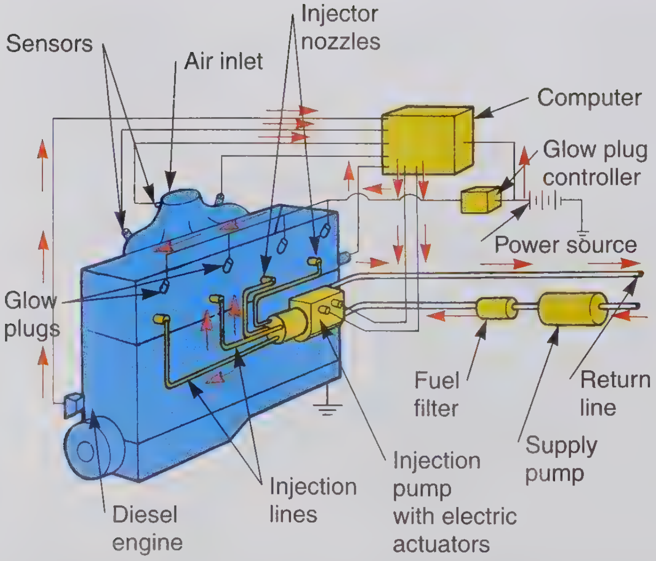

Figure 26-33. Study the basic parts used in an electronic diesel injection system.

Summary

- A diesel fuel injection system is a high-pressure, mechanical system that delivers fuel directly into the engine combustion chambers.
- The injection pump is a high-pressure, mechanical pump that meters the correct amount of fuel and delivers it to each injector nozzle at the proper time.
- Injection lines are high-strength steel tubing that carries fuel to each injector nozzle.
- Injector nozzles are spring-loaded valves that spray fuel into each combustion chamber.
- Glow plugs are electric heating elements that warm air in the precombustion chambers to aid starting of a cold engine.
- Diesel engines use a very high compression ratio (17:1 to 25:1). A gasoline engine's compression ratio is only 8:1 or 9:1.
- A diesel engine is a compression ignition engine because it uses the heat from compressed air to ignite the fuel. Gasoline engines are classified as spark ignition engines because they use an electric arc (from the spark plug) to ignite the fuel.
- A diesel engine has no throttle valve to control airflow into the engine. (Gasoline engines use a throttle valve to control airflow and engine power.) The diesel injection pump controls engine power output.
- A diesel engine compresses air on its compression stroke. A gasoline engine compresses an air-fuel mixture on its compression stroke.
- A diesel engine injects fuel into the combustion chambers. A gasoline engine meters fuel into the intake manifold.

- Injection timing refers to when fuel is injected into the combustion chambers in relation to the engine's piston position.

Review Questions—Chapter 26

Please do not write in this text. Place your answers on a separate sheet of paper.

1. A diesel fuel injection system is a high-pressure, mechanical system that delivers fuel directly to the engine combustion chambers. True or False?
2. Which of the following is *not* related to a diesel engine?
   (A) Spark ignition.
   (B) No throttle valves for air control.
   (C) Fuel quantity controls engine speed.
   (D) All of the above are related to diesel engines.
3. List and explain the four major components of a diesel injection system.
4. There are two common types of diesel injection pumps: ______ and ______ types.
5. What is the function of a plunger in an injection pump?
6. Roller tappets are commonly used in an inline injection pump. True or False?
7. Explain how an inline injection pump alters the amount of fuel forced to the injector nozzles.
8. ______ ______ ______ are spring-loaded valves in the outlet fittings to the injection lines for ensuring quick, leak-free closing of the injector nozzles.
9. Define the term "effective plunger stroke."
10. Why is a governor needed on a diesel engine?
11. ______ ______ refers to when fuel is injected into the combustion chambers in relation to piston position.
12. A(n) ______ ______ ______ normally uses only one or two plungers and is the most common type of diesel injection pump.
13. Which of the following is *not* part of a single-plunger distributor injection pump?
    (A) Drive shaft.
    (B) Fuel metering sleeve.
    (C) Hydraulic head.
    (D) Roller tappet.
14. How does a single-plunger distributor pump develop injection pressure?
15. How does a single-plunger distributor pump control injection quantity?
16. Which of the following is *not* part of a two-plunger distributor injection pump?
    (A) External camshaft.
    (B) Internal cam ring.
    (C) Distributor rotor.
    (D) Fuel metering valve.
17. A vane-type transfer pump is commonly used to pull fuel into the two-plunger distributor injection pump. True or False?

18. An electric fuel shutoff is only used on inline injection pumps. True or False?
19. A diesel _____ _____ is a spring-loaded valve that sprays fuel into the engine precombustion chamber.
20. List and explain the five major parts of a diesel injector.
21. Why are glow plugs needed in a diesel engine?
22. Explain the purpose of a water detector.
23. A(n) _____ _____ can be used to help keep the diesel fuel from jelling in cold weather.
24. A block heater is a heating device operated by the car battery. True or False?
25. Explain why a diesel engine, unlike a gasoline engine, needs a vacuum pump.

ASE-Type Questions

1. Diesel engine compression ratio is about:
   (A) 8:1 to 9:1.
   (B) 10:1 to 12:1.
   (C) 14:1 to 16:1.
   (D) 17:1 to 25:1.
2. Which of the following engine types does *not* use a throttle valve to control airflow into the engine?
   (A) Diesel.
   (B) Gasoline.
   (C) Carburetor.
   (D) None of the above.
3. The spring-loaded valves that spray fuel into each combustion chamber are called:
   (A) injection lines.
   (B) injector pumps.
   (C) injector nozzles.
   (D) supply or lift pumps.
4. Each of the following is a diesel injection pump function *except:*
   (A) produce extremely high fuel pressure.
   (B) open injector nozzles before injection.
   (C) circulate fuel through lines and nozzles.
   (D) control engine idle and maximum speeds.
5. Power is transferred from the engine to the injection pump using a:
   (A) chain.
   (B) set of gears.
   (C) toothed belt.
   (D) Any of the above.
6. With a diesel engine running, Technician A believes the inline injection pump camshaft is rotating at one-half engine speed. Technician B says the camshaft is rotating at engine speed. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Which of the following is used on an inline injection pump to control engine idle speed and limit maximum engine speed?
   (A) Fulcrum.
   (B) Governor.
   (C) Camshaft.
   (D) Control rod.
8. How many plungers does a distributor injection pump use to supply fuel to the engine cylinders?
   (A) One for each cylinder.
   (B) Two for each cylinder.
   (C) One or two for all cylinders.
   (D) None of the above.
9. *All* distributor injection pumps have each of these basic parts *except* a(n):
   (A) delivery valve.
   (B) transfer pump.
   (C) hydraulic head.
   (D) internal cam ring.
10. Which of the following is used to warm start a cold diesel engine?
   (A) Thermo valves.
   (B) Pintaux plugs.
   (C) Glow plugs.
   (D) Thermo sleeves.

Activities—Chapter 26

1. Prepare an overhead transparency showing how the various parts of a diesel injection system are interrelated.
2. Show in a sketch the relationship of a compression ratio of 17:1.
3. Research centrifugal force as a scientific principle, relate this principle to the operation of a governor, and devise a way of demonstrating the principle to the shop class.

27

Diesel Injection Diagnosis, Service, and Repair

After studying this chapter, you will be able to:

- Diagnose typical diesel injection problems.
- List safety precautions pertaining to diesel injection service.
- Test, rebuild, and replace diesel injectors.
- Test and replace glow plugs.
- Perform basic maintenance operations on a diesel injection system.
- Describe basic adjustments common to diesel injection systems.
- Demonstrate safe work habits in diesel injection service.
- Correctly answer ASE certification test questions relating to diesel injection system diagnosis, service, and repair.

It is important for you to understand how to work on a diesel injection system because almost all auto manufacturers offer a diesel engine. While diesel injection service procedures are different from those for a gasoline injection system, they are still relatively simple.

Diesel Injection Maintenance

Refer to a service manual for details on periodic maintenance of a diesel injection system. You must change or clean filters periodically. Maintenance also involves inspecting the system for signs of trouble.

Fuel filters are normally located in the fuel tank (sock filter), in the fuel line (main filter), and, sometimes, in the injector assemblies (inlet connection screens or final filter screens), **Figure 27-1.** To ensure proper engine performance, these filters must be kept clean.

The main fuel filter may have a drain. The drain can be used to bleed off trapped water. When mixed with diesel oil, water causes rapid corrosion and pitting of injection system components.

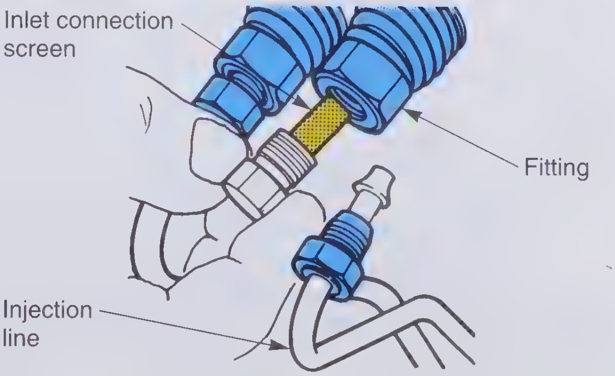

Figure 27-1. Inlet connection screens at injectors are frequently used. Check them if problems point to the injection system. (DaimlerChrysler)

If you detect signs of fuel leakage, use a piece of cardboard to find the leak. See **Figure 27-2.** Move the cardboard around each fuel fitting. If there is a serious leak, fuel will strike the cardboard and not your hand.

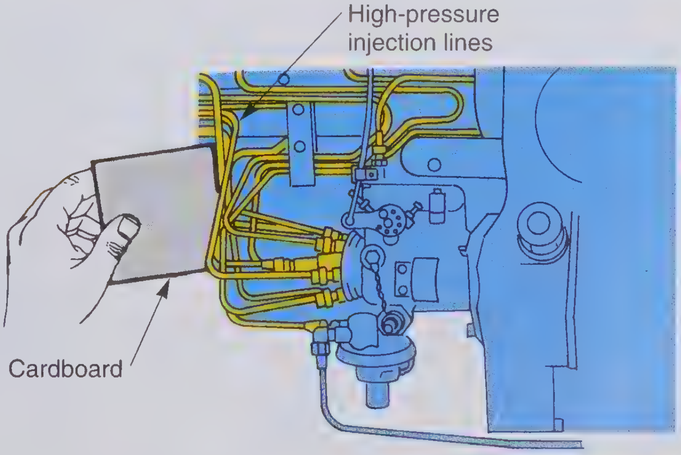

Figure 27-2. Use a piece of cardboard to locate injection system leaks. Remember that injection pressure is high enough to make the fuel spray puncture skin. (DaimlerChrysler)

Replace any injection line or return hose that is not in perfect condition, **Figure 27-3.**

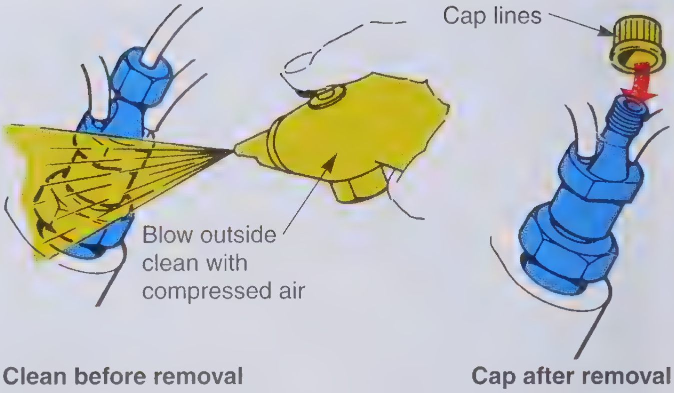
Warning!
Never attempt to stop a diesel engine by covering the air inlet opening. Since there is no throttle valve, there is enough suction to cause a hand injury or to suck rags and other objects into the intake manifold.

Diesel Injection Cleanliness

When servicing a diesel engine, cleanliness is very important. A small bit of foreign material can upset the operation of the injection pump or the injectors. These parts are machined to precision tolerances measured in microns (millionths of a meter). Keep this in mind during service.

A few rules of cleanliness to remember are:

- Always cap and seal any injection system fitting that is disconnected. This will prevent dust from entering the system.
- Use clean, lint-free shop rags when wiping off components. Even a piece of lint could upset the operation of the injection system.
- Use compressed air and clean shop rags to remove dirt from around fittings before disassembly. Look at **Figure 27-4.**
- Do not spray water on a hot diesel engine. This could crack or warp the injection pump.



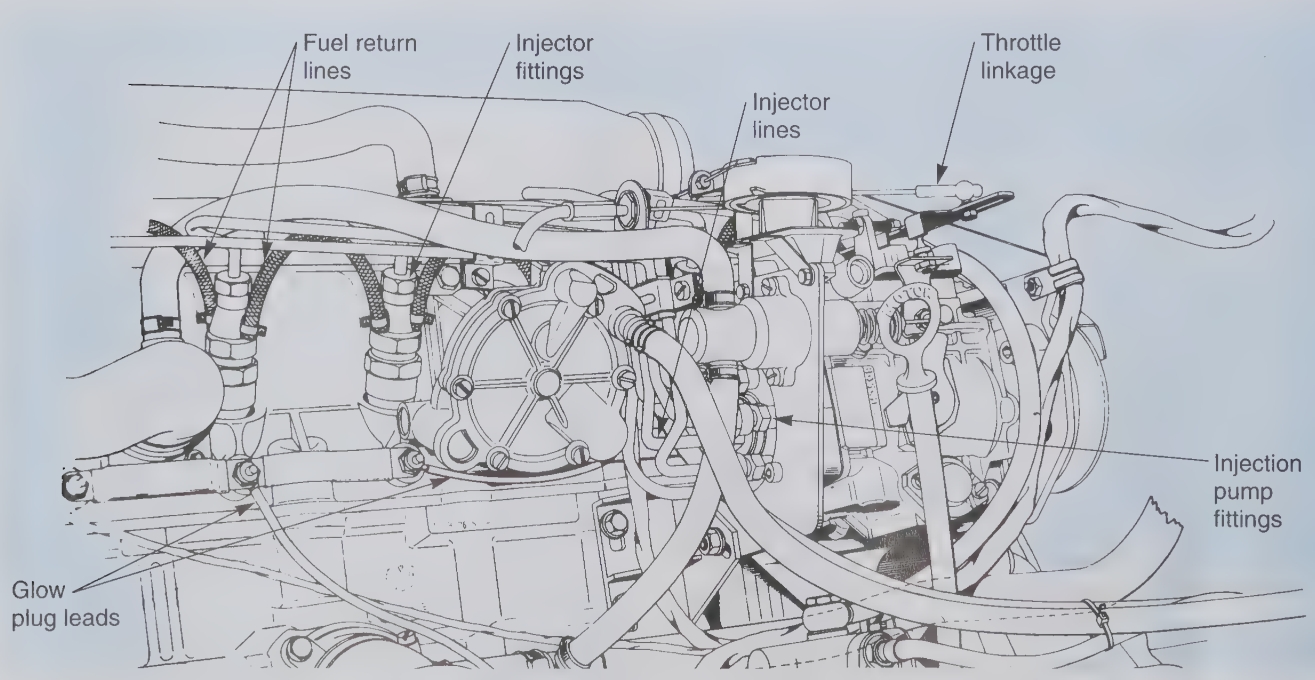
Cap lines
Blow outside clean with compressed air
Clean before removal
Cap after removal

Figure 27-4. Before removing an injection line, blow away dirt with compressed air. Cap the line after it is removed. A small amount of dirt can upset injector operation.

Diesel Injection Diagnosis

Diesel injection diagnosis requires you to use your knowledge of engine and injection system operation and your basic troubleshooting skills. Begin diagnosis by checking the operation of the engine. Check for:

- Abnormal exhaust smoke.
- Excessive knock.
- Engine miss.
- A "no start" condition.
- Lack of power.
- Poor fuel economy.



Fuel return lines
Injector fittings
Throttle linkage
Injector lines
Injection pump fittings
Glow plug leads

Figure 27-3. A visual check of hoses, lines, filters, and linkages will sometimes reveal the source of the problem. (Volvo)

Refer to the troubleshooting chart in the vehicle's service manual. It will list the possible causes for these and other conditions. The service manual chart will be accurate because it is designed for one type of diesel injection system.

Abnormal Exhaust Smoke

Excessive diesel exhaust smoke is normally due to incomplete combustion caused by injection system or engine troubles. A small amount of exhaust smoke is normal during initial start-up, cold engine operation, or rapid acceleration. Abnormal exhaust smoke may be black, white, or blue. See **Figure 27-5.**

The main cause of excessive ***black smoke*** is too much fuel. A rich air-fuel mixture allows carbon (ash) to blow out of the exhaust system. Black smoke may be due to problems with the injection pump, injection timing, air cleaner, injectors, fuel, or the engine itself.

White smoke occurs mainly during cold starts. The smoke usually consists of condensed fuel particles. The cold engine parts cause the fuel to condense into a liquid, which will not burn. The most common reasons for white exhaust smoke are inoperative glow plugs, low engine compression, thermostat stuck open, bad injector spray pattern, late injection timing, and cold start (injection pump) problems.

Tech Tip!
White smoke can also be caused by coolant leakage into the combustion chambers. The engine may have a leaking head gasket, cracked cylinder head, or cracked block.

Excessive ***blue smoke*** may be due to oil consumption from worn piston rings, scored cylinder walls, or leaking valve stem seals. White-blue smoke, however, is normally caused by incomplete combustion or injection system problems.

Smoke Meter

A ***smoke meter*** is a testing device used to measure the amount of smoke (ash or soot) in diesel exhaust. See **Figure 27-6.** The smoke meter measures the amount of light that can shine through an exhaust sample. If the

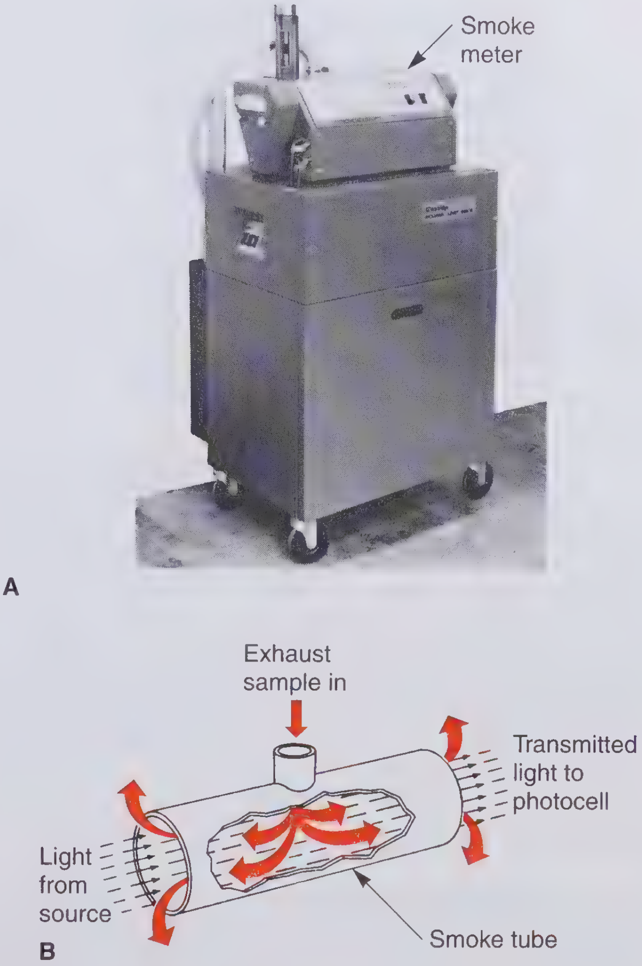


Figure 27-6. A smoke meter can be used to check the amount of smoke in diesel exhaust. A—Smoke meter. B—Principle of smoke meter operation. (Hartridge)

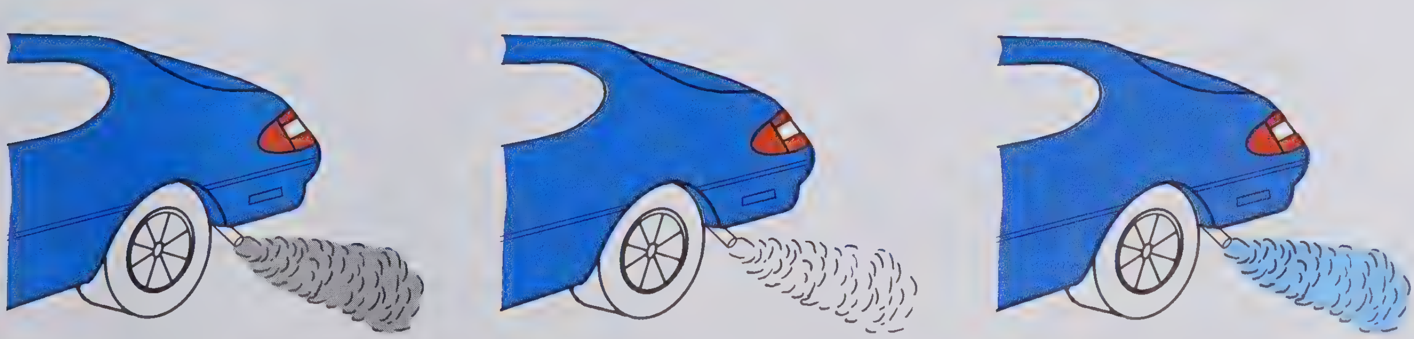

Black smoke—rich fuel mixture **White smoke—partially burned fuel** **Blue smoke—burning oil**

Figure 27-5. Exhaust smoke will tell you much about diesel engine operation.

exhaust smoke blocks too much light, engine or injection system repairs or adjustments are needed.

Excessive Knock

All diesel engines produce a knocking sound when running. This occurs because the fuel ignites spontaneously and burns rapidly. Very high pressures produce a rumble or a dull clattering sound.

Ignition lag is the time span between the injection of the diesel fuel and the ignition of the fuel. It is a controlling factor affecting diesel knock. If ignition lag is too long, too much fuel will ignite at once and a mild explosion (loud knock) will result.

Abnormally loud diesel knock can be due to low operating temperatures (thermostat stuck open), early injection timing, low compression, fuel contamination, and oil consumption.

Engine Miss

A diesel engine ***miss*** results from one or more cylinders not firing (burning fuel) properly. Just as a gasoline engine will miss if a spark plug does not produce a spark, a diesel engine can also run roughly because of injection system problems.

A miss in a diesel engine can be due to faulty injectors, clogged fuel filters, incorrect injection timing, low cylinder compression, injection system leaks, air leaks, or a faulty injection pump.

Engine No Start Condition

A ***no start condition*** may be due to inoperative glow plugs, restricted air or fuel flow, a bad fuel shutoff solenoid, contaminated fuel, or a defective injection pump.

A slow cranking speed is a common cause of a diesel no start condition. Being a compression-ignition engine, a diesel must crank fast enough to produce sufficient heat for combustion.

Lack of Power

When a diesel engine lacks power, check the throttle cable adjustment, governor setting, fuel filters, air filter, engine compression, and other factors affecting combustion. Keep in mind, however, that a diesel engine does not produce as much power as a gasoline engine of equal size.

Poor Fuel Economy

Poor fuel economy may be due to a fuel leak, a clogged air filter, incorrect injection timing, or leaking injectors. Normally, a diesel engine will get better fuel economy than a gasoline engine.

Check the EPA fuel economy values for the vehicle before measuring actual fuel economy. If the measured fuel economy is much lower than the EPA values, adjustments or repairs should be made.

Scanning Diesel Problems

Many late-model diesel engines are computer controlled. You can usually connect a scan tool to the system to aid troubleshooting. An OBD II system will check the injection pump solenoids, electric feed pumps, fuel tank pressure, water sensors, and other devices.

For more information on scanning computer control systems, refer to the index. This subject is explained in several other chapters.

Testing Diesel Injection Operation

There are several ways to check the operation of a diesel injection system. We will briefly explain the most common testing methods. Always refer to your service manual for exact instructions. Recommended testing procedures vary with the design of the injection pump, return lines, and injection nozzles.

Cylinder Balance Test

A diesel ***cylinder balance test*** involves disabling one injector at a time to check the firing of that cylinder. Just as you can remove a spark plug wire on a gasoline engine to check for combustion, you can loosen the injection line to disable the injector.

Warning!
When loosening an injection line, unscrew the fitting only enough to allow fuel to drip from the connection. Wear safety glasses and leather gloves, and obtain instructor approval before completing this test. Also, refer to the service manual because it may describe a safer testing method.

To perform a cylinder balance test on a diesel engine, wrap a rag around the injector and loosen the injector line fitting. See **Figure 27-7.** When the fitting is loosened, fuel should slowly leak out of the connection. Fuel leakage will prevent the injector from opening and spraying fuel into the combustion chamber.

As the injector line is loosened, engine speed should drop and the engine should idle roughly. If “killing” a cylinder does not affect engine operation, that cylinder has not been firing. There may be a bad injector, low compression, or an injection pump problem. Further tests will be needed. Check all injectors.

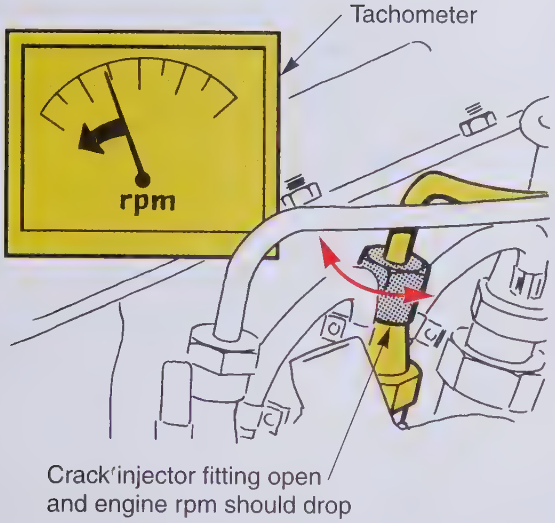

Figure 27-7. To check for a dead cylinder or cylinder not firing, crack open each injector line one at a time. Let fuel drip from fitting with the engine running. This will keep the injector from opening. If engine speed drops, that injector and cylinder are functioning. If engine speed does not drop with injector disabled, that cylinder is not firing. (Volvo)

Diesel Engine Compression Test

A diesel engine ***compression test*** is similar to a compression test for a gasoline engine. However, do not use a compression gauge intended for a gasoline engine on a diesel engine. It can be damaged by the high pressures. A diesel compression gauge must read up to approximately 600 psi (4134 kPa).

To perform a diesel compression test:

1. Remove either the injectors or the glow plugs. Refer to a service manual for instructions.
2. Install the compression gauge in the recommended hole. Usually, a heat shield must be used to seal the gauge when it is installed in place of an injector.
3. Disconnect the fuel shutoff solenoid to disable the injection pump.
4. Crank the engine and note the highest reading on the gauge.
5. Compare your compression gauge readings to specifications.

Typical compression pressure for an automotive diesel engine is 400–500 psi (2800–3400 kPa). Readings should be within about 50–75 psi (350–500 kPa) of each other. If the readings are not within this range, engine repairs are needed.

For more information on compression testing, refer to the text index. Compression testing is covered in several other textbook locations.

Caution!
Some automakers warn against performing a wet compression test on a diesel engine. If too much oil is squirted into the cylinder, hydraulic lock and part damage could result because the oil will not compress.

Glow Plug Resistance-Balance Test

A ***glow plug resistance-balance test*** provides a safe way of finding out if each cylinder is firing. When combustion is occurring in a cylinder, it will raise the temperature and internal resistance of the glow plug in that cylinder.

To perform this test, unplug the wires to all the glow plugs. Connect a digital ohmmeter across each glow plug and ground. Write down the ohms reading of each glow plug. Then, start the engine and let it run for a few minutes. Shut the engine off and recheck glow plug resistance. If a cylinder is not firing, the resistance of its glow plug will not increase as much as the resistance of the others.

Digital Pyrometer Balance Test

A ***digital pyrometer*** is an electronic device that is used to take very accurate temperature measurements. It can sometimes be used to check the operation of a diesel engine.

Touch the digital pyrometer on the exhaust manifold at each exhaust port. With the engine running, the temperature of the exhaust manifold should be almost the same at each port. If the manifold reading is cooler next to one exhaust port, that cylinder is not firing.

Injection-Pressure Test

An ***injection-pressure tester*** uses special valves and a high-pressure gauge to measure the amount of pressure in the injection lines. See **Figure 27-8.**

Connect the injection-pressure tester between the injection pump and the injectors. Follow the instructions provided with the particular tester. Some injection-pressure testers allow you to check the following.

- Injector opening pressure.
- Injector nozzle leakage.
- Injection line pressure balance.
- Injection pump condition.

An injection-pressure tester is a very informative test instrument. It enables you to pinpoint problems without removing major parts from the engine. For example, you can quickly locate a leaking injector nozzle, a clogged injector filter, or a bad injection pump. A leaking nozzle will show up as a pressure drop. A clogged filter will cause higher-than-normal pressure readings. A bad injector pump will produce lower-than-normal pressure readings.

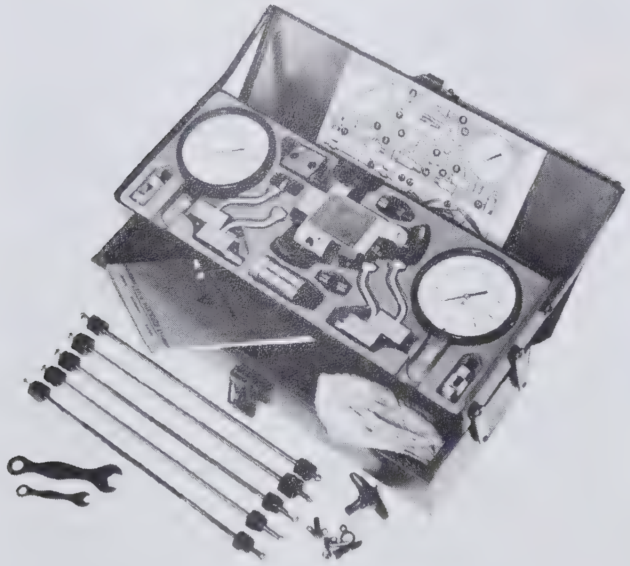

Figure 27-8. Test setup for checking injection system operation while still on engine. This tester makes diagnosis quick and easy. (Hartridge)

Diesel Injection Service

As each diesel injection component is discussed in the following sections, possible symptoms, problems, and corrections for that component will be explained.

Injector Nozzle Service

A bad diesel injector usually causes the engine to miss. It may also reduce engine power or cause smoking and knocking. The injector nozzles are exposed to the direct heat and by-products of combustion. They can wear, become clogged with carbon, or be damaged. This can result in an incorrect opening pressure, incorrect spray pattern, fuel leakage, and other problems.

Injector Substitution

Injector substitution is an easy way to verify an injector problem. It involves installing a good injector for the one being tested. If the cylinder fires with the good injector, then the old injector is faulty. If the cylinder still misses with the good injector, then other engine or injection problems exist.

Injector Removal

If your tests indicate a faulty injector, you should remove the injector for service. Following the directions in the service manual, disconnect the battery to prevent engine cranking. Using the appropriate tools, remove the injection line. Be careful not to bend or kink the high-pressure line.

Normally, the injectors are threaded into the cylinder head, **Figure 27-9.** They may also be held in the head with bolts and a press fit. With press-fit injectors, you may need to use a special impact tool to force them out of the head. See **Figure 27-10.**

Warning!
Never attempt to remove an injection system component with the engine running. With 6000–8000 psi (42,000–56,000 kPa) of fuel pressure, fuel could squirt out and puncture your skin. *Blood poisoning* or *death* could result.

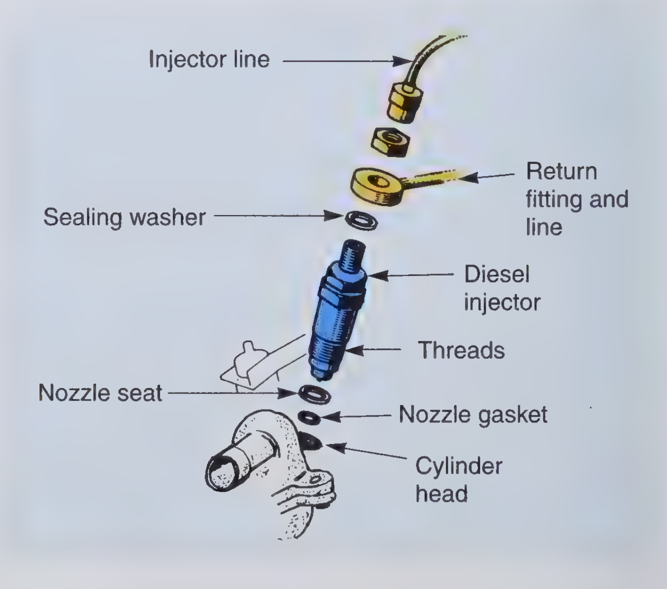

Figure 27-9. When removing an injector, note the position of all parts. This injector screws into the cylinder head. Some are press-fit and clamped into the head. (Toyota)

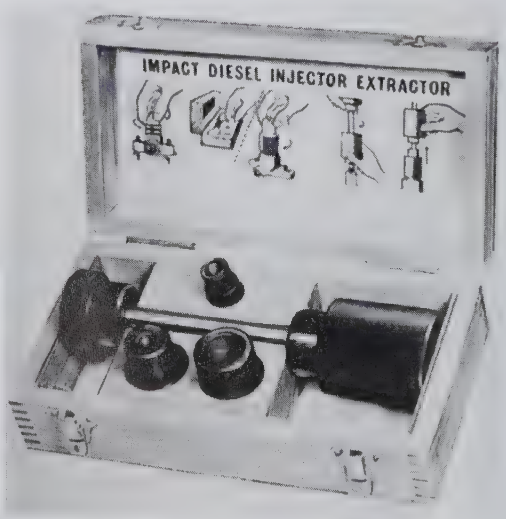

Figure 27-10. An impact or slide hammer puller may be needed to remove press-fit injectors. (Hartridge)

Pop Testing Diesel Injector Nozzles

A ***pop tester*** is a device for checking a diesel injection nozzle while it is out of the engine. One type of pop tester is pictured in **Figure 27-11.**

To use a pop tester:

1. Fill the tester reservoir with the correct calibration fluid (test liquid). Do not use diesel fuel because it is too flammable and test results may not be reliable.
2. Open the tester valve and pump the tester handle.
3. As soon as solid fluid (no air bubbles) sprays out of the tester, close the valve.
4. Connect the injection nozzle to the tester as shown in **Figure 27-12.**
5. To check injector opening pressure, purge any remaining air from the nozzle by pumping the tester lever up and down. Then, pump the handle slowly while watching the pressure gauge.
6. Note the pressure reading when the injection nozzle opens.
7. Repeat the test until you are sure you have an accurate reading.

Warning!
Extremely high pressures are developed when pop testing a diesel injector nozzle. Wear eye protection and keep your hands away from the fuel spraying out of the nozzle. It can puncture the skin.

Typical diesel injector opening pressure is approximately 1700–2200 psi (12,000–15,000 kPa). If opening pressure is not within the service manual specifications, rebuild or replace the injector.

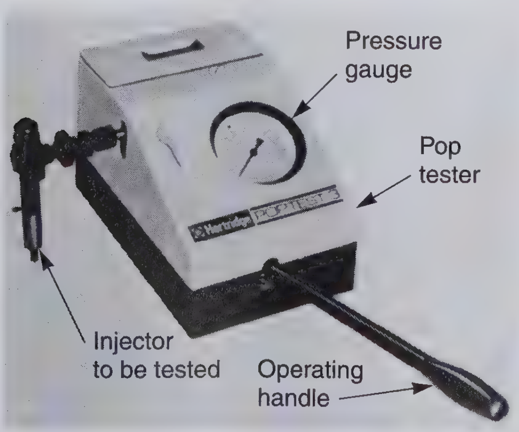

Figure 27-11. This pop tester checks diesel injector operation. It will test the injector spray pattern, opening pressure, and leakage. (Hartridge)

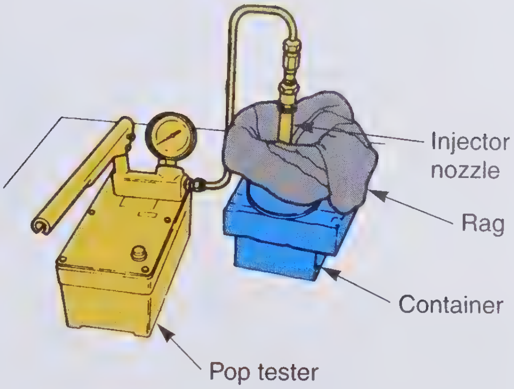

Figure 27-12. To use a pop tester, mount the injector on tester. Point the injector into an approved catch container. Surround the container with rags to prevent splashing. Pump the tester handle while observing the spray pattern, opening pressure, and leakage. Follow directions for the specific tester. (Ford)

To check the injector's ***spray pattern,*** operate the pop tester handle while watching the fluid spray out of the injector nozzle. As shown in **Figure 27-13,** there should be a narrow, cone-shaped mist of fluid. A solid stream of fuel, an uneven spray, an excessively wide spray, or a spray filled with liquid droplets indicates that the injector requires service or replacement.

To check ***injector leakage,*** slowly operate the tester handle to maintain a pressure that is lower than the nozzle opening pressure. Many auto manufacturers recommend a pressure about 300 psi (2000 kPa) below opening pressure. With this pressure, the diesel injector should not leak or drip for 10 seconds. Leakage would point to a dirty injector nozzle or worn components.

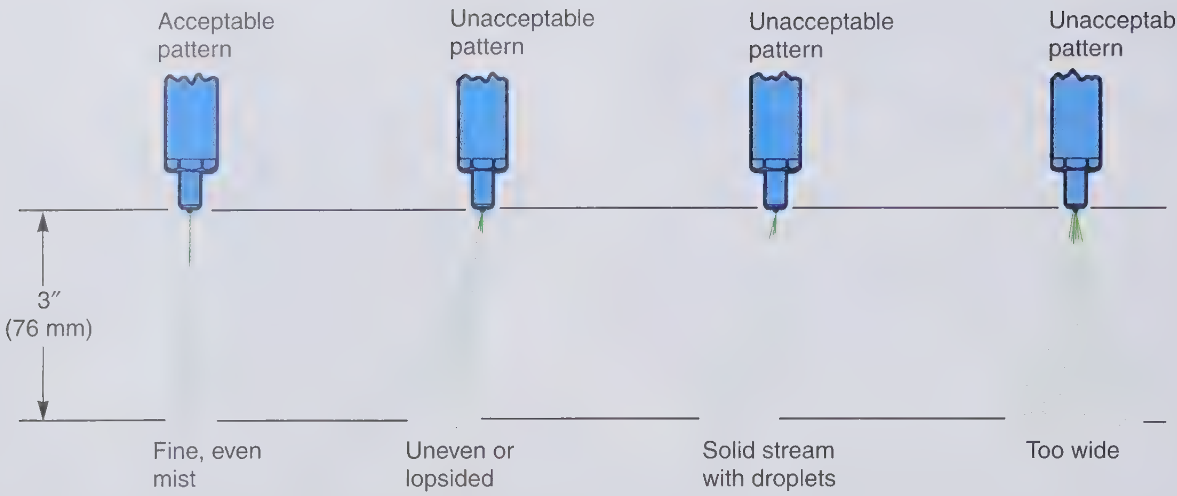
Tech Tip!
Some diesel injectors make a chattering sound during operation; others do not. All nozzles, however, should make a swishing or pinging sound when spraying fuel.

Diesel Injector Nozzle Rebuild

An injector nozzle rebuild involves disassembling, cleaning, inspecting, reassembling, and testing the injector. If faulty parts are discovered during inspection, they must be replaced. Since injector designs vary, always refer to the service manual for detailed instructions. It will give specific assembly methods, torque values, and other critical information.

To disassemble the injector, unscrew the body using a six-point wrench or socket. As illustrated in **Figure 27-14,** remove and inspect the injector needle and nozzle opening.

Clean the nozzle parts in solvent. Special cleaning tools (brass scrapers, brass brushes, etc.) may be needed



Acceptable pattern

Figure 27-14. When rebuilding a diesel injector, be careful not to damage it. Keep all parts together. Clamp the injector lightly in a vise to unscrew the body. Inspect each part closely for carbon buildup, wear, or damage. (VW)

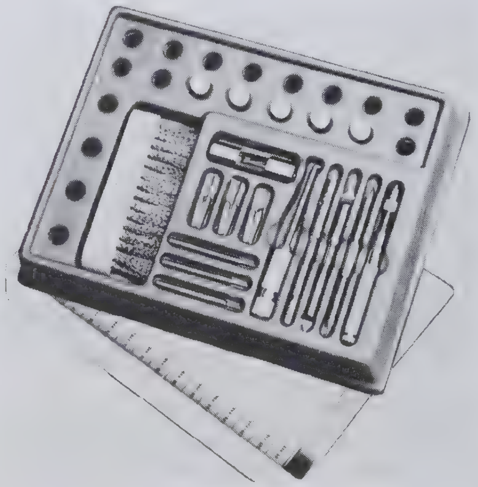

Figure 27-15. Special tool kit for servicing diesel injectors. It contains a soft brush, gauges, and other devices for rebuilding injectors. (Hartridge)

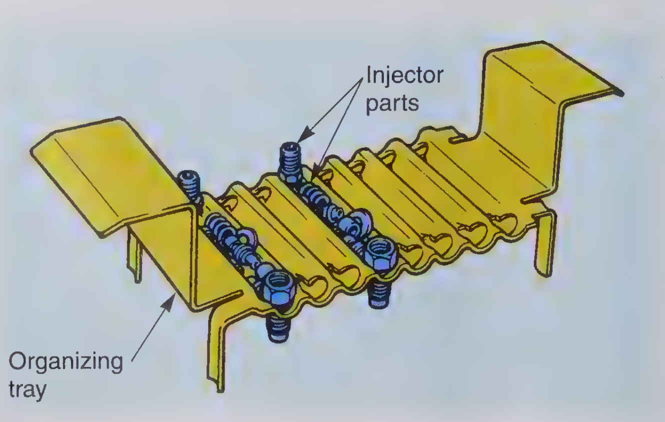
to remove hard carbon deposits, **Figure 27-15.** Use extreme care not to scratch the needle and nozzle. The smallest scratch can upset injector operation. Replace any component that shows signs of wear or damage.

If more than one injector is disassembled, make sure you do not mix parts. Use an organizing tray to keep the parts from each injector separate, **Figure 27-16.** The components in each injector may have been select-fit at the factory and must not be interchanged.



Injector parts
Organizing tray

Figure 27-16. An organizing tray is handy when servicing injectors. It will help prevent a mix-up of parts. If even one part is installed in wrong injector, it may not operate properly. (Buick)

An ***injector shim*** is frequently used to adjust spring tension and valve-opening pressure. If the pop test shows a low opening pressure, install a thicker injector shim. This increases spring tension and raises the opening pressure. The manufacturer will give details on how shim thickness affects pressure.

Reassemble the injector as described in the service manual. Lubricate all parts with diesel fuel. Make sure all parts are positioned properly. Torque the injector body to specifications.

Installing Diesel Injectors

When installing a diesel injector, coat the threads with antiseize compound. Use a new heat shield or seal to prevent compression leakage. Screw the injector into the cylinder head by hand. Then, torque it to the recommended specification. Look at **Figure 27-17.** Reconnect the injector line without bending it. Tighten the connection properly.

Reconnect the wire on the fuel shutoff solenoid and start the engine. Check the system for leaks and proper operation. In a few cases, you may be required to bleed air out of the system. Refer to a manual for exact details.

Caution!
Always double-check that all fittings have been torqued before starting the engine.

Glow Plug Service

Inoperative glow plugs will make a diesel engine hard to start when cold. There will not be enough heat from compression alone to ignite the fuel. If only one or two glow plugs are inoperative, the engine may miss while cold.

If glow plug problems are indicated, use a test light to check for voltage to the glow plugs. Touch the test light on the feed wires to the glow plugs. A clip-on ammeter can also be used to check current to the glow plugs. An incorrect current to the glow plugs can be caused by the supply circuit or by the glow plugs themselves.

Caution!
Refer to a service manual when testing a glow plug circuit. It is possible to damage some glow plugs (6-volt type) by connecting them to direct battery voltage.

An ohmmeter can be used to determine the condition of the glow plugs. Connect the ohmmeter between each glow plug terminal and ground. The resistance should be within specifications. If the resistance is too high or low, replace the glow plug. See **Figure 27-18.**

Glow Plug Replacement

To remove a glow plug, disconnect the wires going to it. Then, use a deep-well socket and ratchet to unscrew the glow plug.

Warning!
A glow plug can reach temperatures above 1000°F (550°C). This can cause serious burns to your hand. Use extreme caution when removing glow plugs from the engine.

When the glow plugs are removed, inspect each one closely. Look for damage or a heavy coating of carbon. A carbon buildup can insulate the plug, making the engine hard to start. Clean any glow plugs that are to be reused. Replace all plugs that are faulty.

When installing the glow plugs, coat their threads with antiseize compound. Start the plugs by hand and then tighten them to specifications. Overtightening can easily damage a glow plug.

Some glow plugs operate on 12 volts, and some operate on 6 volts. Make sure you have the type recommended for the vehicle. Reconnect the wires and check glow plug operation.

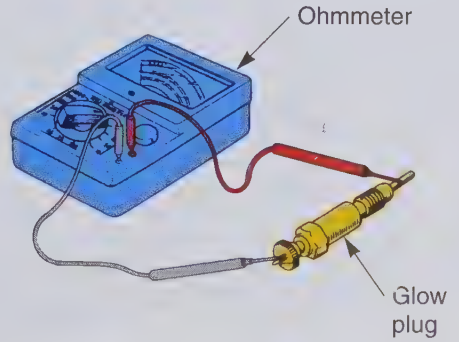

Figure 27-18. Glow plug condition can be checked with a common ohmmeter. Plug resistance must be within specifications. (Toyota)

Injection Pump Service

A bad injection pump can prevent an engine from running and cause engine missing, smoking, and other problems. The injection pump is usually a very trouble-free unit. However, a pump may require replacement, repair, or adjustment due to water contamination, prolonged service, leaking seals, or physical damage.

Most shops install a new or factory-rebuilt diesel injection pump when internal parts are faulty. The injection pump is a very precise mechanism. Specialized tools and equipment are needed for repair work.

Figure 27-19 shows an injection pump test stand, which is used to check pump performance. Its use is normally limited to specialized shops, not automotive shops.

It is sometimes possible to replace leaking external gaskets and seals without major pump disassembly. On most pumps, other external parts (idle stop solenoid, vacuum valve, cold advance solenoid, fuel shut-off solenoid) can also be replaced in the shop. Refer to your service manual for details. See **Figure 27-20.**

To replace a diesel injection pump:

1. Crank the engine until the No. 1 piston is at TDC.
2. Study the timing marks on the pump and engine. This will make reinstallation easier.
3. Disconnect the battery cable to prevent accidental cranking and fuel injection.
4. Remove the injection lines, wires, linkages, and fasteners to allow pump removal, **Figure 27-21.**
5. Cap all lines to keep out dust and dirt.
6. Carefully lift off the old pump.
7. Transfer parts (solenoids, vacuum valves, drive sprocket, etc.) from the old pump to the new pump. See **Figure 27-22.**
8. Install the new pump on the engine.
9. Align the timing marks noted during disassembly.
10. Torque all fasteners and lines properly.
11. Before starting the engine, adjust injection timing as described in the next section.

Caution!
Never hammer or pry on an injection pump housing. Also, be careful not to drop an injection pump. It can be damaged easily and is very expensive to replace.

Lockdown adjustment screws

Figure 27-22. Normally, the vacuum regulator valve must be reused when installing a new or rebuilt injection pump. Adjustment involves a check of vacuum action while rotating the valve on its mount. (General Motors)

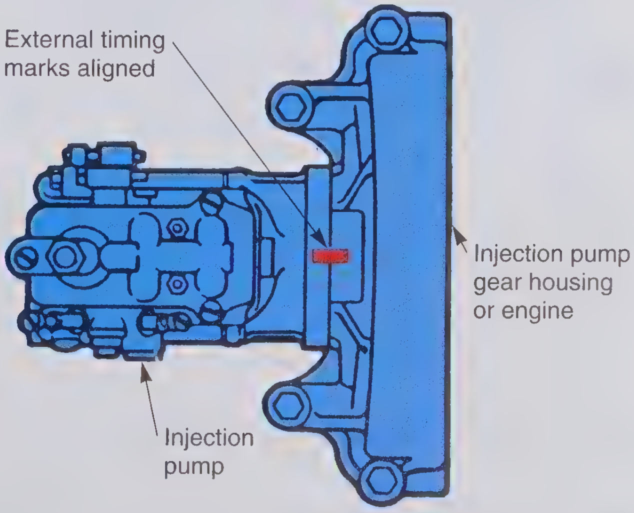
Injection Pump Timing

Diesel injection pump timing is adjusted by rotating the injection pump on its mounting. To advance injection pump timing, turn the pump opposite the direction of pump drive shaft rotation. To retard injection pump timing, turn the pump housing in the same direction as the drive shaft rotation.

Injection pump timing must be set whenever the pump is removed from the engine or when an incorrect adjustment is discovered. There are several methods for adjusting injection pump timing. Procedures vary with the particular type of engine and injection system. A diesel does not have an electrically operated ignition system for triggering a timing light. For this reason, other methods are needed to determine when the No. 1 cylinder fires.

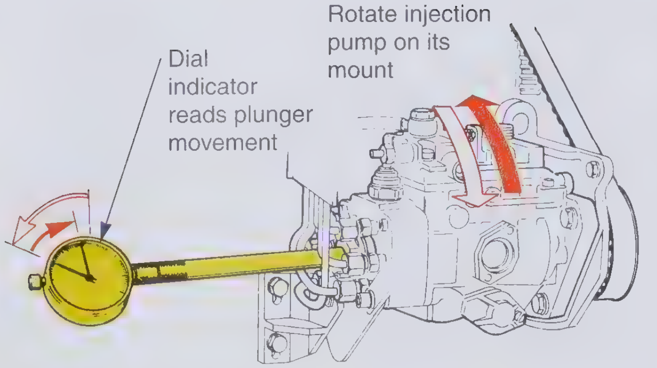
Injection pump timing can be adjusted by several methods:

- Align timing marks on the engine and injection pump with the No. 1 piston at TDC (rough adjustment), **Figure 27-23.**
- Use a dial indicator to measure injection pump stroke in relation to engine piston position. See **Figure 27-24.**
- Use a luminosity (light) device to detect combustion flame in the No. 1 cylinder. Look at **Figure 27-25.**
- Use a fuel pressure (injection) detector to detect the minute flex and ping that occurs as high fuel pressure forces the diesel injection nozzle open.
- Use a scope tool on the crankshaft position sensor and a transducer pickup tool around the No. 1 injection line to see a graphical representation of injection timing. This setup is shown in **Figure 27-26.**



External timing marks aligned
Injection pump gear housing or engine
Injection pump

Figure 27-23. A simple method of setting injection timing involves aligning marks on pump and engine. When the two marks align, the pump should be timed properly. (Ford)



Rotate injection pump on its mount
Dial indicator reads plunger movement

Figure 27-24. Some automakers recommend using a dial indicator when setting injection timing. After removing a plug in the end of the pump, the dial indicator stem is positioned against the plunger. The indicator will then register plunger movement. To change injection timing, rotate the injection pump on the engine. Tighten pump mounting fasteners to lock timing in place. (Volvo)

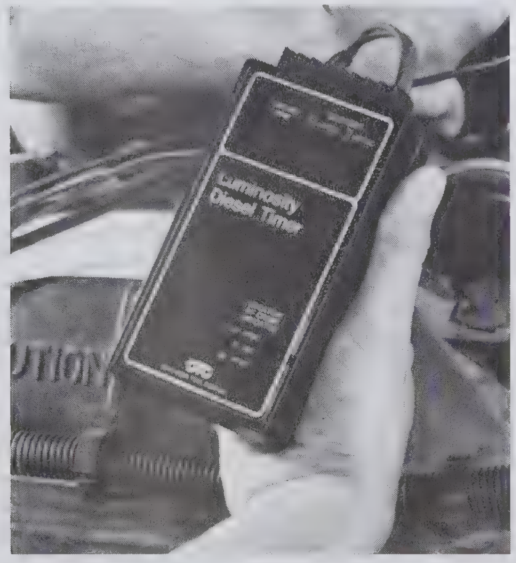


Figure 27-25. A technician using a luminosity meter to detect combustion timing for adjustment of injection timing. (OTC Tools)

Refer to a factory shop manual for details. The manual will describe which adjustment method should be used. Also, follow the operating instructions for the specific type of timing device. Injection timing is very critical to diesel engine performance.

Injection Pump Throttle Cable/Linkage Adjustment

Basically, injection pump throttle cable or linkage adjustment involves making sure the pump's throttle lever opens and closes freely. As parts wear, the cable or linkage may need to be reset. During adjustment, check for binding. Lubricate if needed. Look at **Figure 27-27.** It shows basic adjustments.

A service manual will give exact directions for injection pump cable or linkage adjustment. Typically, you can lengthen or shorten the cable housing or linkage as needed by simply loosening a locknut.

Figure 27-28 shows how a carburetor angle gauge is used to adjust a transmission vacuum regulator valve. Gauge position and valve operation must correspond to specifications.

Diesel Idle Speed Adjustment

There are three speed adjustments commonly used on a diesel injection pump: curb idle speed, fast (cold) idle speed, and maximum speed. See **Figure 27-29.**

Diesel ***idle speed*** is usually set using a special diesel tachometer. An idle stop screw on the injection pump is turned to vary engine speed.

A diesel tachometer may be similar to or part of the injection timing device. It may also be an instrument like the one shown in **Figure 27-30.** With all designs, the diesel tachometer will read engine speed in rpm (revolutions per minute).

Diesel Curb Idle Speed

To adjust diesel ***curb idle speed,*** place the transmission in neutral or park. Start the engine and allow it to run until it reaches full operating temperature. Then, connect the tachometer to the engine.

Compare the readings with the specifications. Curb idle speed will be given on the engine compartment emission control decal or in the service manual.

If needed, turn the curb idle speed adjusting screw on the injection pump to raise or lower idle rpm. Usually, you must loosen a locknut before the screw will turn. Hold the screw and retighten the locknut when the tachometer reads correctly.

Diesel Cold Idle Speed Adjustment

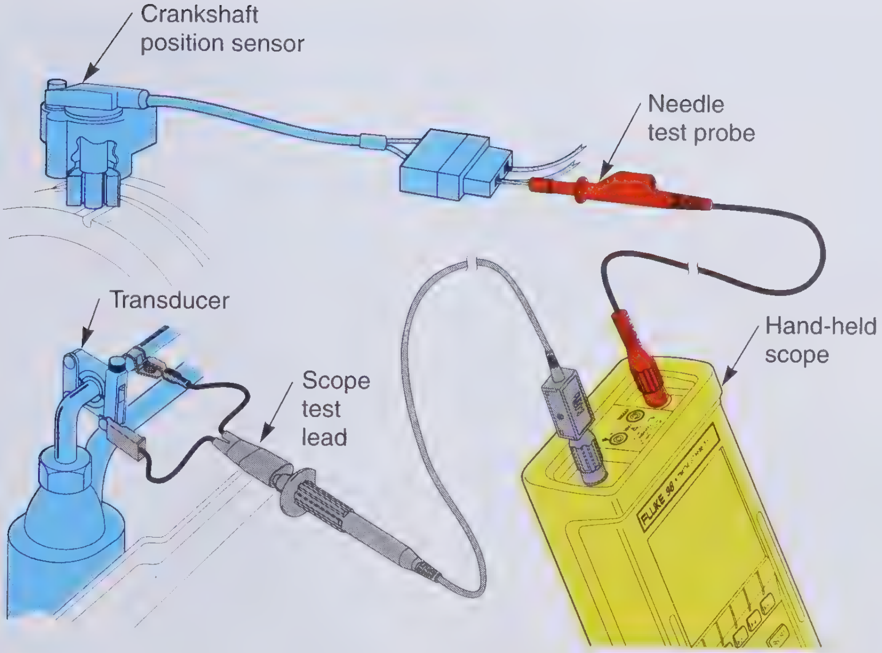
To set diesel ***cold idle speed***, connect a jumper wire from the battery positive terminal to the fast idle solenoid terminal. This will activate the fast idle, even when the engine is warm.

Raise the engine speed momentarily to release the solenoid plunger. Again, compare your tachometer readings to specifications. Adjust the solenoid if needed. Refer to **Figure 27-31.**

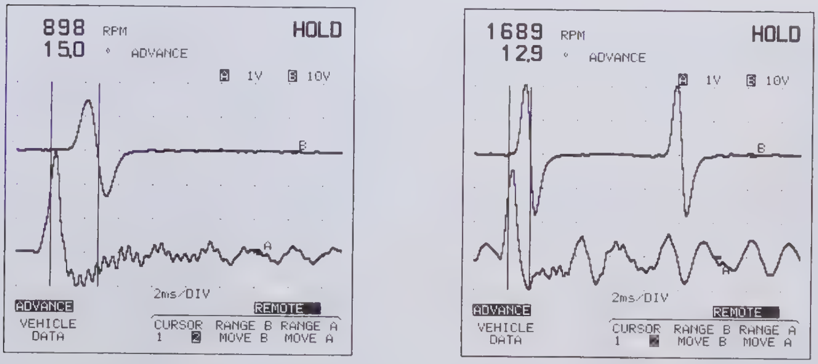
Sometimes a cold start lever replaces a cold idle solenoid. Refer to manufacturer manuals for details.

Diesel Maximum Speed Adjustment

A diesel ***maximum speed adjustment*** is used to limit the highest attainable engine rpm. If maximum governor



A—Note the connections for injection timing measurement if the engine has a crankshaft position sensor. A transducer pickup clamps around the injection line to detect fuel pressure and flow increase from the high-pressure pump.



B—The scope traces and digital readouts show the alignment and amplitude at low engine idle speed.

C—With engine speed increased to 1700 rpm, the scope shows advance of injection timing. Injection occurs sooner, or to left of the scope screen. This gives diesel fuel enough time to burn at higher speeds.

Figure 27-26. If the diesel has crankshaft position sensor, connect a scope to the sensor and a transducer pickup tool around the No. 1 injection line. The tool will then allow you to observe advance-retard (trace movement from side to side) electronically. Rapid, jerky movement of the waveform could mean worn injection pump parts. You can also find weak sensor signal. This scope also gives numerical readout of injection advance. (Fluke)

rpm is too high, engine rpm may exceed specifications and damage to internal engine components may result. If maximum rpm is too low, the engine will not produce enough power.

To adjust the maximum speed of a diesel, position your tachometer so that it can be read from the driver's compartment. With the transmission in neutral or park, hold your left foot on the brake. Press the accelerator pedal slowly to the floor.

Once the tachometer reads the maximum speed specification, engine speed should no longer increase. If the maximum speed is not within specifications, turn the

Computerized Diesel Injection Service

Diagnosing and repairing a diesel system that is controlled by a computer is similar to working on other computer-controlled systems. Some systems have self-diagnostics, which will help indicate the location of problems. You can use a digital meter to check for opens and shorts in wiring and to test the sensors and actuators.

For more information on servicing computer systems, refer to Chapters 17–19.

Diesel Injection Service Rules

When servicing a diesel injection system, remember these basic rules:

- Always cap lines and fittings to prevent the entry of foreign matter.
- Never pry on or drop a diesel injector or injection pump. They can be damaged.
- Remember that high pressure inside a diesel injection system can cause serious injury.
- Clean around fittings before they are disconnected.
- Adhere to all torque specifications. This is extremely important on a diesel engine.
- Never use a bent, frayed, or kinked injection line.
- Some diesel injection systems must be bled (air removed) after repairs.
- Place a piece of screen mesh over the air inlet when the engine is to be operated without the air cleaner.

Rags and other objects can be sucked into the engine. Also, do not cover the air inlet with your hand with the engine running or injury may result.

- Check fuel filters and water separators periodically. Water can corrode expensive injection system parts.
- Follow all safety rules concerning ventilation and fire hazards.
- Wear safety glasses when working on a diesel injection system.
- When in doubt, refer to a service manual for vehicle being serviced. The slightest mistake could upset engine performance or cause engine damage.

Duff's Garage

Problem: Mr. Berkos brings his diesel truck into the shop, complaining of an engine miss.

Diagnosis: Duff questions Mr. Berkos about the nature of the problem. “My engine misses and shakes right after it starts on a cold morning,” Mr. Berkos says. “The strange thing is that the problem seems to go away after the truck runs for a while.”

Duff knows that a diesel engine miss during warm-up is generally a sign of glow plug or injector problems. Duff asks Mr. Berkos to leave the truck overnight so the engine can be started cold. The next morning, Duff starts the engine in an attempt to recreate the problem. Not only is the engine hard to start, but it misses just as Mr. Berkos had explained.

Duff assigns the repair to the shop's diesel specialist, who also suspects a glow plug problem. The technician inspects the engine compartment for obvious problems but finds none. He then starts the cold engine and uses an inductive ammeter to check for current at the glow plug wires. Normal current draw is measured at all the glow plugs but one. Using an ohmmeter, the technician checks the resistance of the glow plug that is not receiving the specified current. The ohmmeter shows infinite resistance, indicating an open in the glow plug heating element.

Repair: The technician installs a new glow plug to replace the “dead one.” The engine is again allowed to cool overnight. The next morning, the engine starts easily and does not seem to miss.

Summary

- Refer to a service manual for details on periodic maintenance of a diesel injection system.
- Diesel injection diagnosis requires you to use your knowledge of engine and injection system operation, as well as your basic troubleshooting skills.
- Excessive diesel exhaust smoke is normally due to incomplete combustion caused by injection system problems or engine troubles.
- Ignition lag is the time span between the injection of the diesel fuel and the ignition of the fuel.
- A diesel engine miss results from one or more cylinders not firing properly.
- Never attempt to remove an injection system component when the engine is running. With 6000–8000 psi (42,000–56,000 kPa) fuel pressure, fuel could squirt out and puncture your skin. Blood poisoning or death could result.
- A diesel cylinder balance test involves disabling one injector at a time to check the firing of the cylinders.
- A glow plug resistance-balance test provides a safe way to find out if each cylinder is firing.
- A bad diesel injector usually causes the engine to miss. It may also reduce engine power or cause smoking and knocking.
- Injector substitution is an easy way to verify an injector problem.
- A pop tester is a device used to check injector spray pattern, opening pressure, and leakage.
- Inoperative glow plugs will make a cold diesel engine hard to start.
- A bad injection pump can keep the engine from running or cause engine missing, smoking, and other problems.
- Diesel injection pump timing is adjusted by rotating the injection pump on its mounting.
- Diesel idle speed is usually set while using a special diesel tachometer. An idle stop screw on the injection pump is turned to vary engine speed.

Review Questions—Chapter 27

Please do not write in this text. Place your answers on a separate sheet of paper.

1. The main fuel filter will often have a water drain that must be serviced periodically. True or False?
2. The parts in a diesel injection pump can be machined so precisely that they are measured in millionths of a meter. True or False?
3. What is the main cause of black smoke from a diesel engine?
4. Explain the most common reasons for excessive white smoke from a diesel engine.
5. Excessive _____ smoke from a diesel may be due to oil consumption from worn _____ _____, scored _____ _____, or leaking _____ _____.
6. A smoke meter is for measuring the amount of smoke in diesel exhaust. True or False?
7. Which of the following is *not* a normal cause of excessive diesel knock?
   (A) Long ignition lag time.
   (B) Low engine-operating temperature.
   (C) Early injection timing.
   (D) All of the above are normal causes of excessive knock.
8. Explain a diesel cylinder balance test.
9. A compression gauge reading up to 250 psi (1,723 kPa) can be used to measure compression pressure in a diesel engine. True or False?
10. What are typical compression test readings for a diesel engine in good condition?
11. Why do many service manuals warn against doing a wet compression test on a diesel?
12. A glow plug _____-_____ test relies on the fact that glow plug electrical resistance increases with temperature.
13. How can a digital pyrometer be used to check the operation of a diesel engine?
14. What four values do some on-car injection-pressure testers allow you to measure?
15. Injector nozzles are exposed to combustion and can become clogged with carbon. True or False?
16. Which of the following should *not* be done when removing a diesel injector?
   (A) Disconnect battery.
   (B) Bend injection line out of the way.
   (C) Use impact tool if needed.
   (D) All of the above should be done when removing a diesel injector.
17. A diesel engine has a dead miss (one cylinder not firing). Engine analyzer cranking tests indicate good engine compression. Technician A says all of the injectors should be removed and rebuilt. They must be at fault. Technician B says you should perform a cylinder balance test or on-car pressure tests. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
18. Explain the use of a pop tester.
19. Injector nozzle parts can be interchanged. True or False?
20. Inoperative _____ _____ will make a diesel engine hard to start when cold.
21. Which of the following can be used to test diesel glow plug system operation?
   (A) Test light.
   (B) Ammeter.
   (C) Ohmmeter.
   (D) All of the above.
22. Glow plugs can reach temperatures above _____ °F or _____ °C.
23. Tests show that a diesel injection pump has an internal problem. Technician A says the pump should be disassembled and repaired. Technician B says the pump should be replaced with a new or factory-rebuilt unit. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
24. What is an injection pump test stand?
25. Explain four methods of adjusting diesel injection timing.

ASE-Type Questions

1. Which of the following is sometimes located in the injector assemblies?
   (A) Sock filter.
   (B) Main filter.
   (C) Final filter screens.
   (D) All of the above.
2. Diesel injection parts are machined to precision tolerances measured in:
   (A) inches.
   (B) microns.
   (C) millimeters.
   (D) centimeters.
3. Which smoke color indicates engine oil is entering the combustion chamber?
   (A) Blue.
   (B) Black.
   (C) White.
   (D) All of the above.
4. Abnormally loud diesel knock can be caused by each of these *except:*
   (A) oil consumption.
   (B) rich fuel mixture.
   (C) fuel contamination.
   (D) early injection timing.
5. This is *not* a cause of diesel engine miss:
   (A) air leak.
   (B) faulty injectors.
   (C) clogged fuel filters.
   (D) shorted fuel cutoff solenoid.
6. Which of these tests involves disabling one injector at a time?
   (A) Cylinder balance test.
   (B) Injection-pressure test.
   (C) Diesel compression test.
   (D) Digital pyrometer balance test.
7. Compression pressure for an automotive diesel engine is:
   (A) 50–75 psi.
   (B) 100–200 psi.
   (C) 300–375 psi.
   (D) 400–500 psi.
8. When checking diesel injection nozzles with a pop tester, Technician A believes the tester reservoir should be filled with the correct diesel oil. Technician B feels the tester reservoir should be filled with the correct calibration fluid. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. When replacing an injection pump, which of the following need to be transferred from the old pump to the new pump?
   (A) Solenoids.
   (B) Vacuum valves.
   (C) Drive sprockets.
   (D) All of the above.
10. Injection pump timing can be adjusted by using any of these *except:*
    (A) light device.
    (B) dial indicator.
    (C) digital pyrometer.
    (D) fuel pressure detector.

Activities—Chapter 27

1. Prepare an overhead transparency on the steps for troubleshooting the injectors in a vehicle that has abnormal exhaust smoke. Use it to demonstrate the steps to your class.
2. Perform a cylinder balance test on the engine's injectors.
3. Using an ohmmeter, demonstrate the proper method for checking the condition of a glow plug.

Diesel Engine Diagnosis

Condition	Possible Cause	Correction
Low power output.	1. Low engine rpm.	1. Adjust governor linkage to rest against the high idle stop when accelerator pedal is depressed. Adjust high idle rpm with adjustment screw. If proper setting cannot be made, disassemble, inspect, and service governor.
	2. Restriction in air inlet system.	2. Inspect air cleaner element and ductwork for damage and excessive bends and turns. Install new air cleaner element.
	3. Water in fuel.	3. Test for fuel in water. Drain fuel tank as needed to remove water. Install new fuel filters and fill tanks with clean fuel.
	4. Fuel with low specific gravity.	4. Test fuel API gravity. Replace fuel if API gravity is greater than 38.
	5. Low fuel pressure.	5. Check fuel pressure.
	6. Fuel rack setting incorrect.	6. Check rack setting and adjust if needed.
	7. Fuel too hot due to blocked constant bleed valve.	7. Check by removing fuel return line and checking for sufficient fuel flow from valve. Replace valve if blocked.
Misfiring and rough running.	1. Air in fuel system.	1. Bleed air from lines.
	2. Fuel injection timing incorrect.	2. Check and make necessary adjustments.
	3. Automatic timing advance malfunction.	3. Check for correct timing. Replace timing mechanism if defective.
	4. Defective fuel nozzles.	4. Locate misfiring injector; clean and service as required.
	5. Incorrect camshaft timing.	5. Check timing.
	6. Fuel leakage at nozzle nut or adapter.	6. Tighten nut to specifications.
Black or gray exhaust smoke (engine runs smooth).	1. High altitude operation at 2500 ft. (762 m) or greater.	1. Adjust fuel rack position.
	2. Dirty air cleaner.	2. Replace dirty air cleaner element.
	3. Air inlet system restriction.	3. Inspect ductwork for damage and/or excessive turns and bends. Adjust or repair as needed.
	4. Fuel injection timing incorrect.	4. Check and make necessary adjustments.
	5. Fuel rack setting incorrect.	5. Check rack setting and adjust to specifications as needed.
	6. Fuel with low specific gravity.	6. Test fuel API gravity.
	7. Leaking fuel nozzles.	7. Locate misfiring injector and service as required.
Black or gray exhaust smoke (engine runs rough).	1. Automatic timing advance malfunction.	1. Check for correct timing. If light is not available, check for smooth acceleration from low to high idle.
	2. Air in fuel system.	2. Check for leaks and bleed air from system.
White exhaust smoke.	1. Cold outside temperatures.	1. Normal condition until engine warms to operating temperature.
	2. Long idle periods.	2. Reduce unnecessary idling or use fuel heating system.
	3. Fuel with low specific gravity.	3. Test fuel API gravity.
	4. Air in fuel system.	4. Check for leaks and bleed air from system.
	5. Fuel injection timing incorrect.	5. Check and make necessary adjustments.
	6. Automatic timing advance malfunction.	6. Check for correct timing.
	7. Bad fuel nozzles.	7. Locate misfiring injector. Clean and service as required.

Diesel Engine Diagnosis

Condition	Possible Cause	Correction
Excessive fuel consumption.	1. Air inlet system restriction.	1. Inspect ductwork for damage and/or excessive turns and bends.
	2. External fuel system leakage.	2. Check fuel system external piping and tubing for signs of leaks. Repair as needed.
	3. Fuel injection timing incorrect.	3. Check and make necessary adjustments.
	4. Leaking fuel nozzles.	4. Locate leaking injector and service as required.
	5. Fuel injection pump calibration incorrect.	5. Remove injection pump and nozzle assemblies from engine. Check calibration and adjust.
Erratic engine speed.	1. Air leaks in fuel system.	1. Check for air leaks and make needed repairs.
	2. Throttle linkage loose or out of adjustment.	2. Check and adjust linkage.
	3. Injection pump governor failure.	3. Check injection pump for damaged or broken springs or other components. Check fuel rack for free travel. Check for correct governor spring. Install new parts as needed and recalibrate injection pump.
Engine stalls at low speeds.	1. Idle speed too low.	1. Adjust idle as required.
	2. Fuel tank vent plugged.	2. Check vent arrangement and make needed repairs.
	3. Low fuel supply.	3. Check tank for fuel. Check fuel lines for sharp bends and restrictions. Check fuel pressure. If pressure is low, replace fuel filters. If pressure is still low, replace transfer pump. Bleed fuel system.
	4. Defective fuel injection nozzle or pump.	4. Inspect, test, and replace nozzle parts or injection pump.
Engine does not reach no-load governed speed.	1. Air in fuel system.	1. Check for leaks and bleed air from lines.
	2. Accelerator linkage loose or misadjusted.	2. Check linkage and adjust as needed.
	3. Restricted fuel lines/stuck overflow valve.	3. Check for restrictions and for defective spring, poor valve setting, or sticking. Make all necessary repairs.
	4. High idle adjustment set too low.	4. Check setting and adjust as needed.
	5. Fuel injection pump calibrated incorrectly.	5. Remove injection pump and nozzle assemblies from engine and recalibrate.
	6. Internal fuel pump governor wear.	6. Remove injection pump from engine and make all necessary repairs.
Difficult starting (crankshaft turns).	1. Cold outside temperatures.	1. Use starting aids.
	2. Air in fuel system.	2. Bleed air from lines.
	3. Water in fuel.	3. Test for water in fuel. Drain fuel tank as needed to remove water. Install new fuel filter and fill tanks with clean fuel.
	4. Low fuel pressure.	4. Check fuel pressure at fuel pump housing.
	5. Fuel injection timing incorrect.	5. Check and make necessary adjustments.
	6. Bad fuel nozzles.	6. Locate misfiring injector and clean and service as required.
	7. No exhaust smoke visible while starting.	7. No fuel in tank. Tank valves inadvertently closed. No fuel from injection pump due to cold weather waxing or fuel line restriction. Faulty fuel injection pump shut-off solenoid. Repair as needed.

28

Exhaust Systems, Turbochargers, and Superchargers

After studying this chapter, you will be able to:

- Describe the basic parts of an exhaust system.
- Compare exhaust system design differences.
- Perform exhaust system repairs.
- Explain the fundamental parts of a turbocharging system.
- Describe the construction and operation of a turbocharger and waste gate.
- Remove and replace a turbocharger and waste gate
- Summarize the construction and operation of a supercharging system.
- Demonstrate an understanding of safety procedures for working on exhaust systems, turbochargers, and superchargers.
- Correctly answer ASE certification test questions on exhaust system, turbocharger, and supercharger operation and service.

This chapter begins by describing the basic parts of an exhaust system. It then explains how to remove and replace rusted or damaged exhaust system components. The second section of the chapter covers the theory and repair of turbocharging and supercharging systems.

Exhaust Systems

An ***exhaust system*** quiets engine operation and carries exhaust gases to the rear of the vehicle. Typical parts, which are shown in **Figure 28-1,** include the following:

- ***Exhaust manifold***—connects the cylinder head exhaust ports to header pipe.
- ***Header pipe***—steel tubing that carries exhaust gases from the exhaust manifold to the catalytic converter or muffler.
- ***Catalytic converter***—device that removes pollutants from engine exhaust.
- ***Intermediate pipe***—tubing sometimes used between the header pipe and muffler or catalytic converter and muffler.
- ***Muffler***—metal chamber for damping pressure pulsations to reduce exhaust noise.
- ***Tailpipe***—tubing that carries exhaust from the muffler to the rear of car body.
- ***Hangers***—devices for securing the exhaust system to the underside of the car body.
- ***Heat shields***—metal plates that prevent exhaust heat from transferring into another object.
- ***Exhaust system clamps***—U-bolts for connecting parts of the exhaust system together.

When an engine is running, extremely hot gases blow out of the cylinder head exhaust ports. The gases enter the exhaust manifold. They flow through the header pipe, catalytic converter, intermediate pipe, muffler, and tailpipe.

Many header pipes are connected to the exhaust manifold by a spring-loaded coupling. The coupling compresses and holds the "doughnut" seal between the exhaust manifold and header pipe. This design allows the engine to move on its motor mounts without moving the exhaust system and damaging the seal.

Exhaust Back Pressure

Exhaust back pressure is the pressure developed in the exhaust system when the engine is running. High back pressure reduces engine power. A well-designed exhaust system should have low back pressure.

The size of the exhaust pipes, catalytic converter, and muffler contributes to exhaust back pressure. Larger pipes and a free-flowing muffler, for example, would reduce back pressure.

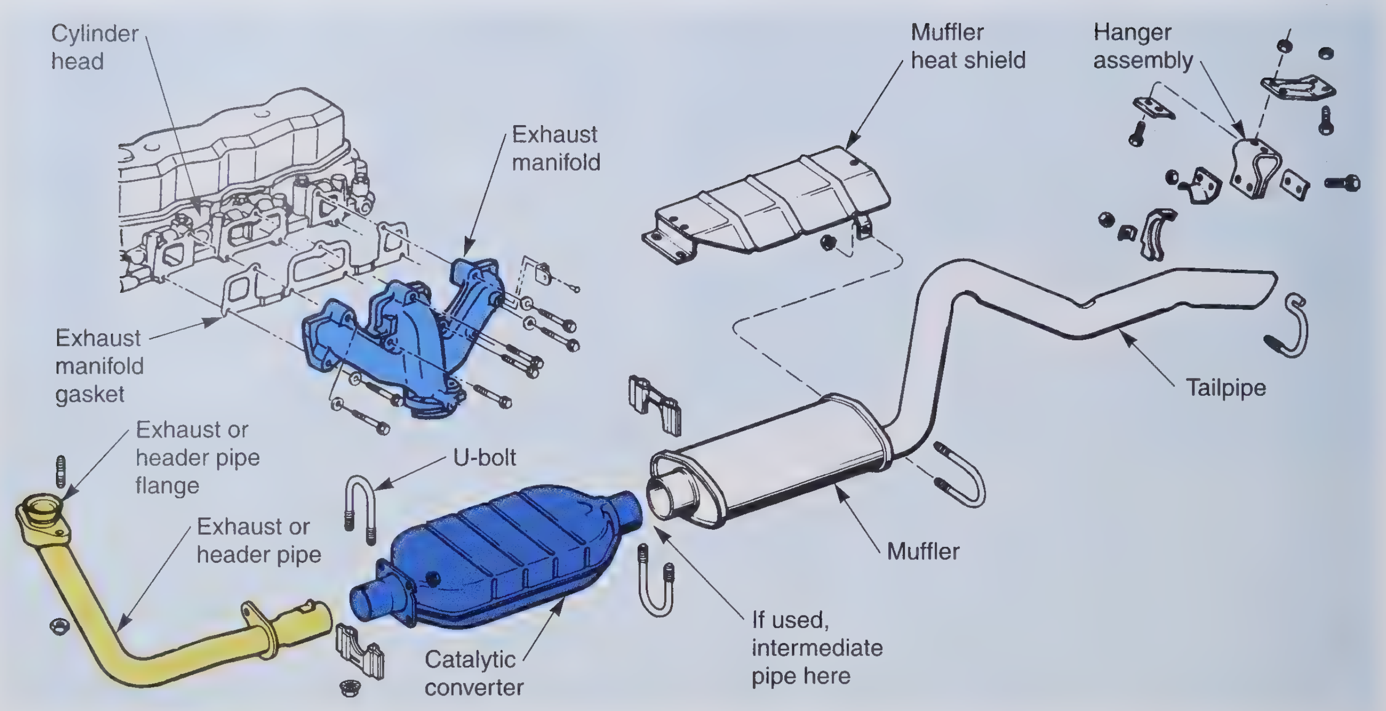

Figure 28-1. Note the parts of a typical exhaust system. Exhaust comes out of the cylinder head, into the manifold, and then through system. (DaimlerChrysler)

Single and Dual Exhaust Systems

A ***single exhaust system*** has one path for exhaust flow through the system. Typically, it has only one header pipe, a main catalytic converter, a muffler, and a tailpipe. The most common type of exhaust system, it is used from the smallest four-cylinder engines on up to large V-8 engines.

A ***dual exhaust system*** has two separate exhaust paths to reduce back pressure. It is essentially two single exhaust systems used on one engine. A dual exhaust system is sometimes used on high-performance cars with large V-6 or V-8 engines. It lets the engine "breath" better at high rpm.

A ***crossover pipe*** normally connects the right and left header pipes to equalize back pressure in a dual system. This also increases engine power slightly.

Exhaust Manifold

An exhaust manifold bolts to the cylinder head to enclose the exhaust port openings, **Figure 28-2.** The manifold is usually made of cast iron. High-flow, high-performance manifolds, which are commonly called headers, are sometimes made of stainless steel or light-weight steel tubing.

The cylinder head mating surface is machined smooth and flat. An exhaust manifold gasket is commonly used between the cylinder head and manifold to help prevent leakage. The outlet end of the exhaust manifold has a round opening with holes for stud bolts or cap screws. A gasket or an O-ring (***exhaust manifold doughnut***) seals the connection between the exhaust manifold outlet and header pipe to prevent leakage.

Exhaust Manifold Heat Valve

The ***exhaust manifold heat valve,*** also called the heat control valve or the heat riser, forces hot exhaust gas to flow into the intake manifold to aid cold weather starting. Look at **Figure 28-3.**

An exhaust manifold heat valve may be located in the outlet of the exhaust manifold. A heat-sensitive spring or a vacuum diaphragm and temperature sensing vacuum switch operate the butterfly valve.

When the engine is cold, the valve is closed. This increases exhaust system back pressure. Hot exhaust gases flow into an exhaust passage in the intake manifold, **Figure 28-4.** This warms the floor of the intake manifold to hasten fuel vaporization. The manifold heat valve opens as the engine warms up.

Exhaust Pipes

The ***exhaust pipes*** (header pipe, intermediate pipe, and tailpipe) are usually made of rust-resistant steel tubing. One end of each pipe may be enlarged to fit over the end of the next pipe. The inlet end of the header pipe

Engine intake manifold
Hot exhaust when heat valve is shut

Figure 28-4. The heat control valve increases back pressure in exhaust system. This directs a large amount of hot exhaust into a chamber in the bottom of intake manifold. This action warms and helps vaporize fuel. (Pontiac)

has a flange for securing the pipe to the exhaust manifold studs, **Figure 28-1.**

Heat Shields

Heat shields are located in areas where the exhaust system components (especially the catalytic converter and muffler) are close to the vehicle's body or near the ground. The shields reduce the amount of heat transferred into the body and protect items under the vehicle. Refer to **Figure 28-1.**

Warning!
Always reinstall all exhaust system heat shields. If the heat shields are not installed, undercoating, carpeting, dry leaves on the ground, and other flammable materials could catch on fire!

Catalytic Converter

A catalytic converter is an "afterburner" used to reduce the amount of exhaust pollutants entering the atmosphere. One or more catalytic converters can be located in the exhaust system, **Figure 28-1.** For information on catalytic converters, refer to Chapter 43, *Emission Control Systems,* and Chapter 44, *Emission Control System Testing, Service, and Repair.*

Muffler

A muffler reduces the pressure pulses and quiets the resulting noise produced by the engine exhaust. When an engine is running, the exhaust valves are rapidly opening and closing. Each time an exhaust valve opens, a blast of hot gas shoots out of the engine. Without a muffler, these exhaust gas pulsations would roar very loudly.

Figure 28-5 shows the inside of a muffler. Note how chambers, tubes, holes, and baffles are arranged to cancel out the pressure pulsations in the exhaust.

Figure 28-5. Mufflers contain baffles, resonance chambers, and acoustic tubes to reduce exhaust noise. (American Exhaust Industries)

Exhaust System Service

Exhaust system service is usually needed when a component in the system rusts and begins to leak. Engine combustion produces water and acids. Therefore, an exhaust system can corrode and fail in a relatively short time.

A leaking exhaust can allow toxic gases to flow through any opening in the car's body and into the passenger compartment. People have died from engine exhaust fumes!

Exhaust System Inspection

To inspect an exhaust system, raise the car on a lift. Using a droplight, closely inspect the system for problems (rusting, loose connections, leaks). Pay particular attention to the muffler and all pipe connections, gaskets, and pipe bends. ***Exhaust leaks*** will often show up as gray or white carbon lines coming from openings.

Warning!
Parts of the exhaust system, especially the catalytic converter, can be very hot. Do not touch any hot part until after it has cooled.

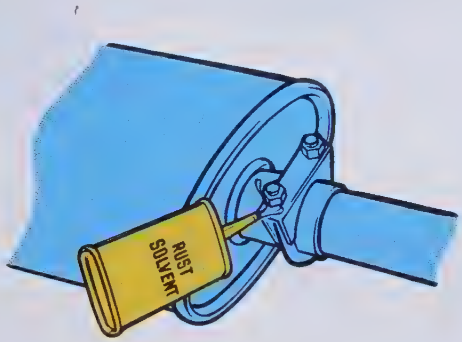
Exhaust System Repairs

Faulty exhaust system parts must be removed and replaced. If only the muffler is rusted, a new muffler can be installed in the existing system. After prolonged service, several parts or the entire exhaust system may require replacement.

When repairing an exhaust system, remember the following:

- Use rust penetrant on all threaded fasteners that will be reused, **Figure 28-6.** This is especially important on the exhaust manifold flange nuts or bolts.
- Use an air chisel, cut-off tool, cutting torch, or hacksaw to remove faulty parts. Make sure you do not damage parts that will be reused. See **Figure 28-7** for some examples.

- A six-point socket and ratchet or an impact wrench will usually allow quick fastener removal without rounding off the fastener heads. Refer to **Figure 28-8.**
- Wear safety glasses or goggles to keep rust and dirt from entering your eyes.
- Obtain the correct replacement parts.
- A pipe expander should be used to enlarge pipe ends as needed, **Figure 28-9.** A pipe shaper can be used to straighten dented pipe ends, **Figure 28-10.**
- Position all clamps properly, **Figure 28-11.**
- Install any necessary adapters. See **Figure 28-12.**
- Make sure all pipes are fully inserted.
- Double-check the routing of the exhaust system. Keep adequate clearance between the exhaust system components and the vehicle's body and chassis. See **Figure 28-13.**



RUST SOLVENT

Muffler
1/8″
(3 mm)

Figure 28-11. Make sure muffler clamps are installed correctly. The clamp must be positioned around both pipes. If not, one pipe can pull out of the other. (Florida Dept. of Voc. Ed.)

- Tighten all clamps and hangers evenly. Torque the fasteners only enough to hold the parts. Overtightening will smash and deform the pipes, possibly causing leakage, **Figure 28-14.**
- When replacing an exhaust manifold, use a gasket and check sealing surface flatness. If the manifold

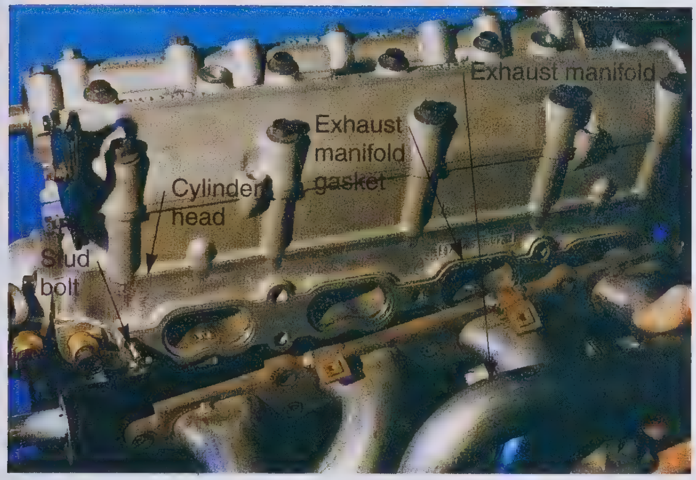

Figure 28-15. An exhaust gasket is often recommended. The gasket is held in position as all fasteners are started by hand. Torque fasteners to recommended value in a crisscross pattern. (General Motors)

is warped, it must be machined flat. Torque the exhaust manifold bolts to specification, **Figure 28-15.**

- Always use new gaskets and O-rings.
- Check heat valve operation using the information in a service manual.
- Install all heat shields.
- Check the system for leaks and rattles after repairs.

Stainless Steel Exhaust System Repairs

Many new vehicle exhaust systems are made of stainless steel. Stainless steel will not rust and will provide much longer service life than ordinary steel systems.

When servicing stainless steel exhaust systems, use heavy-duty clamps designed for this type of system. Conventional muffler clamps are not strong enough and may allow dangerous exhaust gas leakage. They will not compress the stiff stainless steel pipe enough to make a good connection.

When cutting or welding stainless steel, use the correct rod or wire material. Keep in mind that stainless steel does not react in the same manner as carbon steel when heated near its melting point. Stainless steel can be "red hot" when it looks cool.

Superchargers and Turbochargers

A ***normally aspirated engine***, also called an ***atmospheric engine,*** uses atmospheric pressure (14.7 psi or 100 kPa at sea level) to push air into the engine. With outside air pressure as a moving force, only a limited amount of fuel can be burned on each power stroke.

The term *supercharger* originally meant that some type of air pump was used to increase engine power by pushing more air and fuel into the combustion chambers. With a greater amount of air and fuel (a denser air-fuel mixture), combustion can generate more heat energy and pressure to push the pistons down in their cylinders.

A ***supercharger*** is a blower driven by a belt, gears, or a chain. Superchargers are used on large diesel truck engines and racing engines. They are sometimes found on high-performance passenger cars.

The ***turbocharger,*** or ***"turbo,"*** is a blower driven by engine exhaust gases. Turbochargers are commonly used on passenger cars, trucks, and competition engines.

Sometimes called a ***blower,*** the supercharger or turbocharger raises the air pressure in the engine intake manifold. Then, when the intake valves open, more air-fuel mixture (gasoline engine) or air (diesel engine) can flow into the cylinders. Engine horsepower can be doubled in racing applications with engine modifications and a blower.

Turbochargers

A turbocharger is an exhaust-driven fan or blower that forces air into the engine under pressure. Turbochargers are frequently used on small gasoline and diesel engines to increase power output. By harnessing exhaust energy, a turbocharger can also improve engine efficiency (fuel economy and emission levels). This is especially true with diesel engines.

The basic parts of a turbocharger are shown in **Figure 28-16**:

- ***Turbine wheel***—exhaust-driven fan that turns the turbo shaft and compressor wheel.
- ***Turbine housing***—outer enclosure that routes exhaust gases around the turbine wheel.
- ***Turbo shaft***—steel shaft that connects the turbine and compressor wheels. It passes through the center of the bearing housing.
- ***Compressor wheel***—driven fan that forces air into the engine intake manifold under pressure.
- ***Compressor housing***—part of the turbo housing that surrounds the compressor wheel. Its shape helps pump air into the engine.
- ***Bearing housing***—enclosure around the turbo shaft that contains bearings, seals, and oil passages.

Tech Tip!
Some late-model turbocharger impellers are made of carbon fiber–reinforced plastic. This can cut impeller weight in half and reduce the problem of turbo lag considerably.

Piston

Figure 28-16. A turbocharger uses exhaust gas flow to spin a turbine wheel. The turbine wheel spins a shaft and a compressor wheel. The compressor wheel then pressurizes the air entering the engine for more power output. (DaimlerChrysler)

Turbocharger Operation

When the engine is running, hot exhaust gases blow out through the open exhaust valve ports and into the exhaust manifold. The exhaust manifold and connecting tubing route these gases into the turbine housing. Refer to **Figure 28-17.**

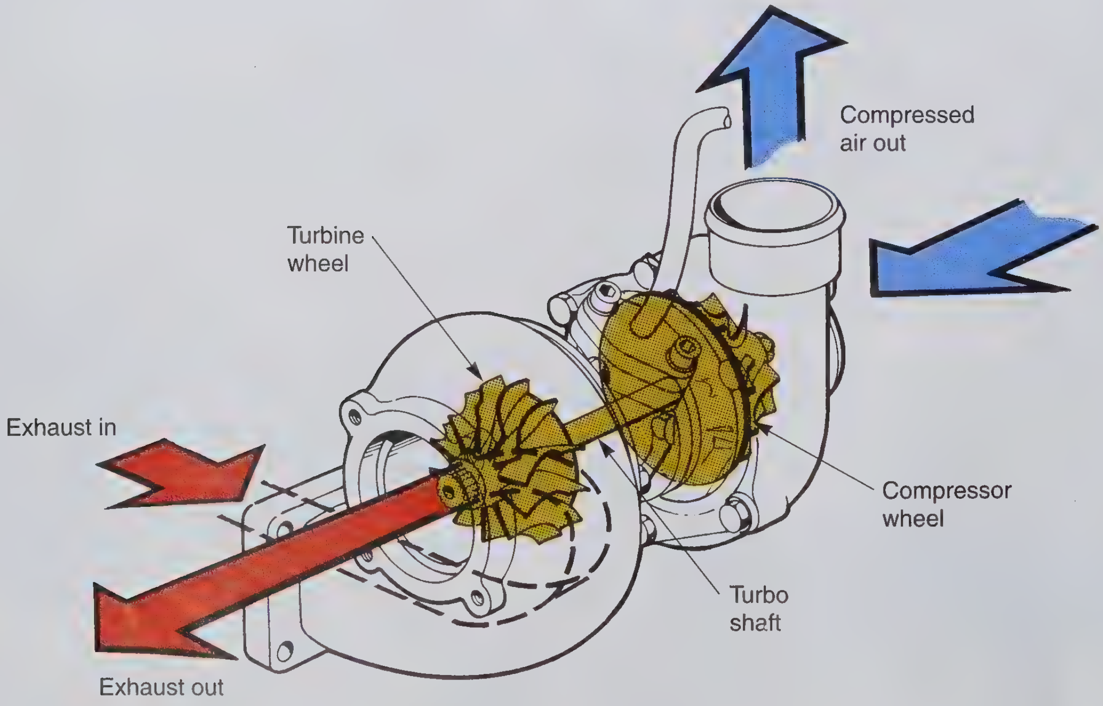
As the gases pass through the turbine housing, they strike the fins on the turbine wheel. When engine load is high enough, there is enough exhaust gas flow to rapidly spin the turbine wheel, **Figure 28-17.**

Since the turbine wheel is connected to the compressor wheel by the turbo shaft, the compressor wheel rotates with the turbine. Compressor wheel rotation pulls air into the compressor housing. Centrifugal force throws the spinning air outward. This causes air to flow out of the turbocharger and into the engine cylinder under pressure.

Turbocharger Location

A turbocharger is usually located on one side of the engine. An exhaust pipe connects the engine exhaust manifold to the turbine housing. The exhaust system header pipe connects to the outlet of the turbine housing. See **Figure 28-18.**

A ***blow-through turbo system*** has the turbocharger located before the carburetor or throttle body. The turbo compressor wheel only pressurizes air. Fuel is mixed with the air after air leaves the compressor.



Compressed air out
Turbine wheel
Exhaust in
Compressor wheel
Turbo shaft
Exhaust out

Figure 28-17. Exhaust flow spins the turbine wheel shaft and the compressor wheel. Normally, wasted energy in exhaust is used to increase compression stroke pressure in cylinders for more violent combustion. (Saab)

A ***draw-through turbo system*** locates the turbocharger after the carburetor or throttle body assembly. As a result, both air and fuel (gasoline engine) pass through the compressor housing in carburetor systems and throttle body fuel injection system. In port fuel injection systems, only air passes through the housing.

Theoretically, the turbocharger should be located as close to the engine exhaust manifold as possible. Then, a maximum amount of exhaust heat will enter the turbine housing. This ensures that the gases are still expanding as they enter the turbocharger. This expansion will help spin the turbocharger, increasing boost pressure and engine power.

Turbocharger Lubrication

Turbocharger lubrication is needed to protect the turbo shaft and bearings from damage. A turbocharger can operate at speeds up to 100,000 rpm. For this reason, the engine lubrication system forces motor oil into the turbo shaft bearings, **Figure 28-19.**

Oil passages are provided in the turbo housing and bearings. An oil supply line runs from the engine to the turbo. With the engine running, oil enters the turbo under pressure.

Sealing rings (piston-type rings) are placed around the turbo shaft at each end of the turbo housing. They prevent oil leakage into the compressor and turbine housings, **Figure 28-19.** A ***drain passage*** and ***drain line*** allow oil to return to the oil pan after passing through the turbo bearings.

Turbo Lag

Turbo lag refers to a short delay before the turbo develops sufficient boost (pressure above atmospheric pressure) to meet engine demands. See **Figure 28-20.**

When the car's accelerator pedal is pressed down for rapid acceleration, the engine may lack power for a few seconds. This is caused by the compressor and turbine wheels not spinning fast enough. It takes time for the exhaust gas to bring the turbo up to operating speed.

Modern turbo systems suffer very little from turbo lag. Their turbine and compressor wheels are very light so that they can accelerate up to speed quickly. Some engines use two smaller turbines, called "twin turbos," to reduce rotating mass and turbo lag.

Turbocharger Intercooler

A ***turbocharger intercooler*** is an air-to-air heat exchanger that cools the air entering the engine. It is a

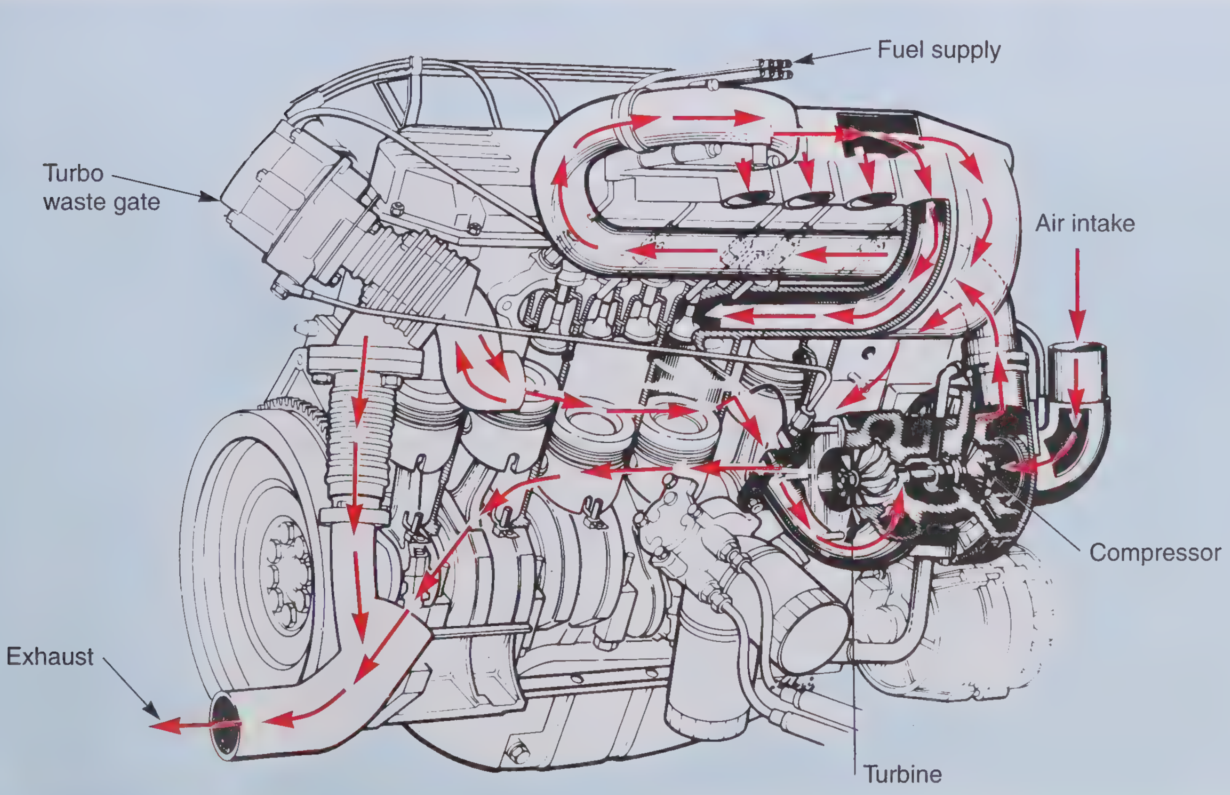


Figure 28-18. Turbocharger normally bolts to one side of engine. Pipes route exhaust through turbine housing. Compressed air leaves turbo and enters intake tract and engine. (Audi)

Figure 28-20. Modern turbo systems suffer very little from turbo lag. Their turbine and compressor wheels are small and light, and spin up to speed quickly. (Saab)

radiator-like device mounted at the pressure outlet of the turbocharger (or supercharger). See **Figure 28-21.**

When you compress air, its temperature increases. Since hot air contains less energy-providing oxygen by volume, it will produce less power. A cooler charge of air is denser and can be mixed with more fuel to increase combustion and engine power.

Outside air flows over and cools the fins and tubes of the intercooler. Then, as the air flows through the intercooler, heat is removed. By cooling the air entering the engine, engine power is increased. Cooling also reduces the tendency for engine detonation.

Waste Gate

A ***waste gate*** limits the amount of boost pressure developed by the turbocharger. It is a butterfly or poppet-type valve that allows exhaust to bypass the turbine wheel. See **Figure 28-22.**

Without a waste gate, the turbo could produce too much pressure in the combustion chambers. This could lead to detonation (spontaneous combustion) and engine damage.

Figure 28-22. Study basic exhaust and inlet airflow through complete turbo system. (Ford)

Basically, a waste gate is a valve operated by a diaphragm assembly, **Figure 28-23.** Intake manifold pressure acts on the diaphragm to control waste gate valve action. The valve controls the opening and closing of a passage around the turbine housing.

Waste Gate Operation

Figure 28-24 illustrates the basic operation of a turbocharger waste gate. Under partial load, the system routes all the exhaust gases through the turbine housing. The waste gate is closed by the diaphragm spring. This

ensures that there is adequate boost to increase engine power.

Under full load, boost may become high enough to overcome the diaphragm spring pressure. Manifold pressure compresses the spring and opens the waste gate valve. This permits some of the exhaust gases to flow through the waste gate passage and into the exhaust system. Less exhaust is left to spin the turbine. Boost pressure is limited to a preset value.

Turbocharged Engine Modifications

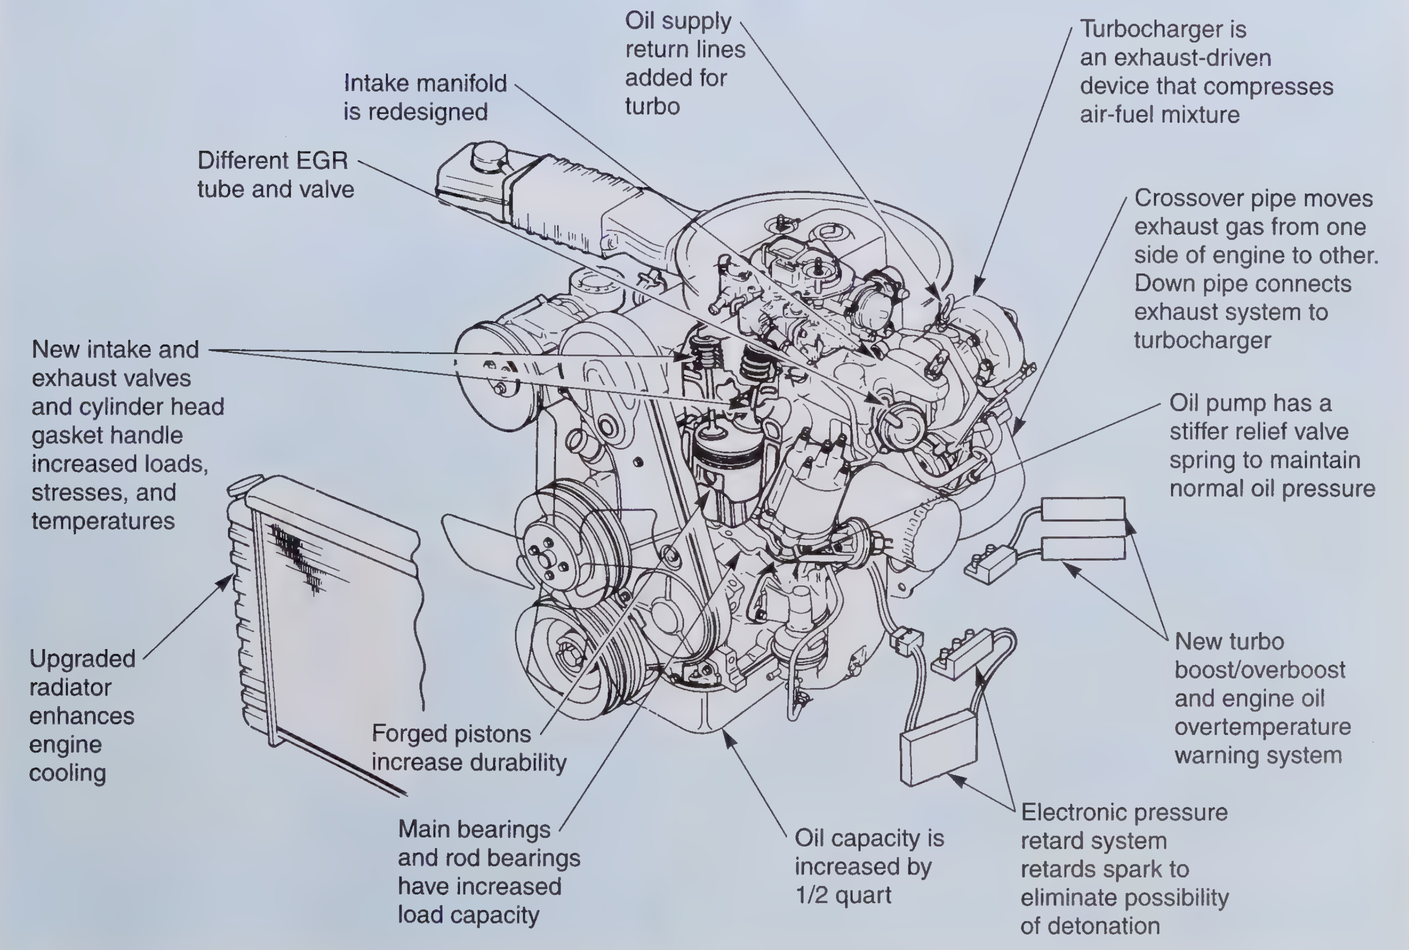
A turbocharged engine normally has several modifications to make it withstand the increased horsepower. A few of these are shown in **Figure 28-25** and include:

- Lower compression ratio.
- Stronger rods, pistons, and crankshaft.
- Higher volume oil pump and an oil cooler.
- Larger cooling system radiator.
- O-ring type head gasket.
- Heat resistant valves.
- Knock sensor (ignition retard system).

Turbo Computer Control

As with other systems, the vehicle computer often controls the turbocharger by operating the waste gate and by retarding the ignition timing when needed. As shown in **Figure 28-26,** several sensor input signals are sent to the computer. These commonly include inputs from the manifold absolute pressure sensor (boost pressure), manifold air temperature sensor, knock sensor, throttle position sensor, and other sensors.

The computer uses preprogrammed data to determine if boost pressure or ignition timing should be altered. The computer must limit boost and timing advance to prevent knock and possible engine damage. It can then produce outputs to open the waste gate or retard timing if needed.



Oil supply return lines added for turbo
Intake manifold is redesigned
Different EGR tube and valve
Turbocharger is an exhaust-driven device that compresses air-fuel mixture
Crossover pipe moves exhaust gas from one side of engine to other. Down pipe connects exhaust system to turbocharger
New intake and exhaust valves and cylinder head gasket handle increased loads, stresses, and temperatures
Oil pump has a stiffer relief valve spring to maintain normal oil pressure
Upgraded radiator enhances engine cooling
New turbo boost/overboost and engine oil overtemperature warning system
Forged pistons increase durability
Main bearings and rod bearings have increased load capacity
Oil capacity is increased by 1/2 quart
Electronic pressure retard system retards spark to eliminate possibility of detonation

Figure 28-25. Note many engine modifications are commonly used with turbocharging. Turbocharging increases demands on engine. (Ford)

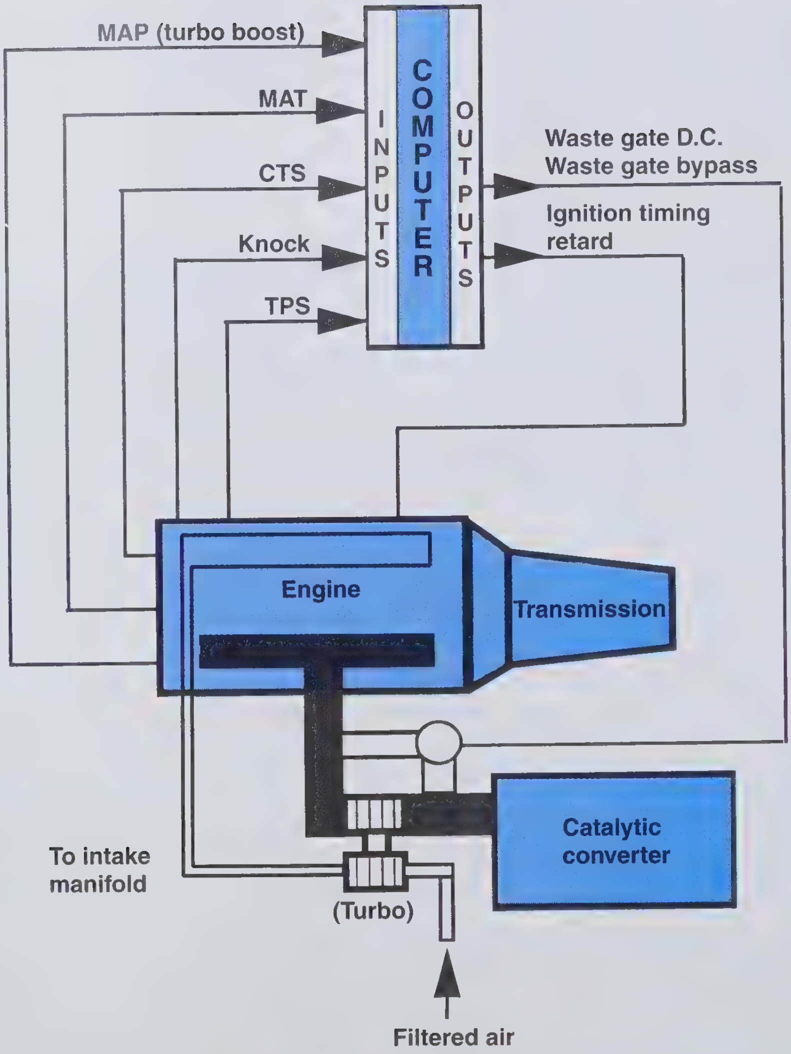


Figure 28-26. The on-board computer is commonly used to monitor and control the turbocharging system. Note how sensors feed data to the computer and how the computer can then output current signals to retard ignition timing or open waste gate. (OTC)

A ***knock sensor*** signals the engine control module if the engine begins to knock (detonate or ping). The sensor is mounted on the engine. It works somewhat like a microphone. When it "hears" a knocking sound, an electrical signal is sent to the control module. The control module then retards the timing until the knock stops.

A knock sensor helps the control module keep the ignition timing advanced as much as possible. This improves engine power and gas mileage. The knock sensor also protects the engine from detonation damage. The knock sensor is one of the most important sensors in a computer-controlled turbocharger system.

Turbocharging System Service

Turbocharging system problems usually show up as inadequate boost pressure (lack of engine power), leaking shaft seals (oil consumption), damaged turbine or compressor wheels (vibration and noise), or excess boost (detonation).

To protect a turbocharger from damage, most automakers recommend that the oil in a turbocharged engine be changed frequently (about every 3000 miles or 4827 km). Because of the high rotating speeds, the turbo bearings and shaft are very sensitive to oil contaminants. Engine oil must be kept clean to ensure long turbocharger life.

Scanning a Turbocharging System

Use a scan tool to check for trouble codes relating to the turbocharging system. Late-model OBD II systems may show codes for the knock sensor, throttle position sensor, manifold pressure sensor, manifold temperature sensor, and other sensors. These codes can all relate to the turbo system.

Tech Tip!
Remember that on-board diagnostic systems and scan tools can sometimes be "confused" by mechanical problems. For example, a worn piston pin can knock and "fool" the knock sensor into thinking the engine is detonating. It will then mistakenly retard ignition timing and lower boost pressure. A trouble code might be tripped when something else is causing the problem. Keep this in mind when using a scan tool.

Refer to a factory service manual for a detailed troubleshooting chart. It will list the common troubles for the particular turbocharging system.

Checking a Turbocharging System

There are several checks that can be made to determine turbocharging system condition:

- Check connection of all vacuum lines to the waste gate and oil lines to the turbocharger, **Figure 28-27.**
- Use a regulated low-pressure air hose to check for waste gate diaphragm leakage and operation.
- Use the dash gauge or a test gauge to measure boost pressure (pressure developed by turbo under a load). If needed, connect the pressure gauge to an intake manifold fitting. Compare the gauge readings to specifications.
- Use a stethoscope to listen for bad turbocharger bearings.

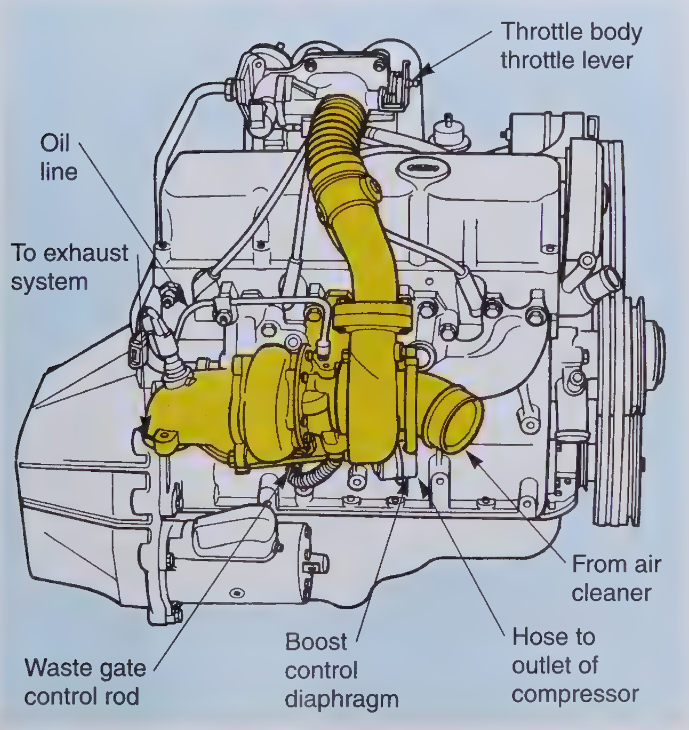

Figure 28-27. Side view of engine shows location and mounting of turbocharger. (Ford)

Checking a Turbocharger

To check the internal condition of a turbocharger, remove the unit from the engine, as in **Figure 28-28.** Unbolt the connections at the turbo. Remove the oil lines and take the unit to your workbench.

Inspect the turbocharger wheels for physical damage. The slightest nick or dent will throw the unit out of balance, causing vibration. **Figure 28-29** shows how to measure turbo bearing and shaft wear.

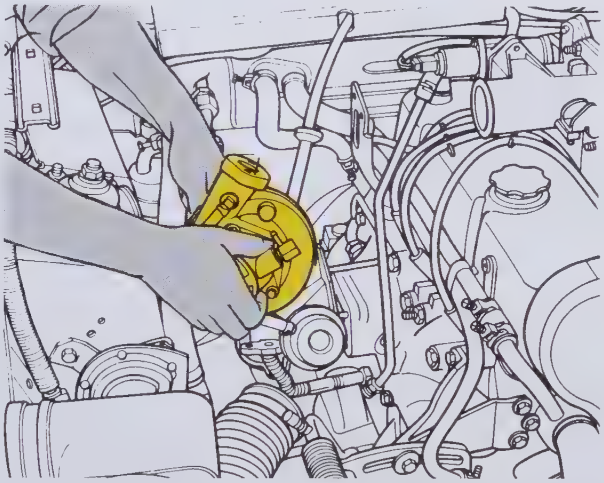

Figure 28-28. After removing mounting fasteners and any other parts, a turbocharger can be lifted off for replacement. A turbo cannot be repaired in the shop. A new unit is normally installed. (Ford)

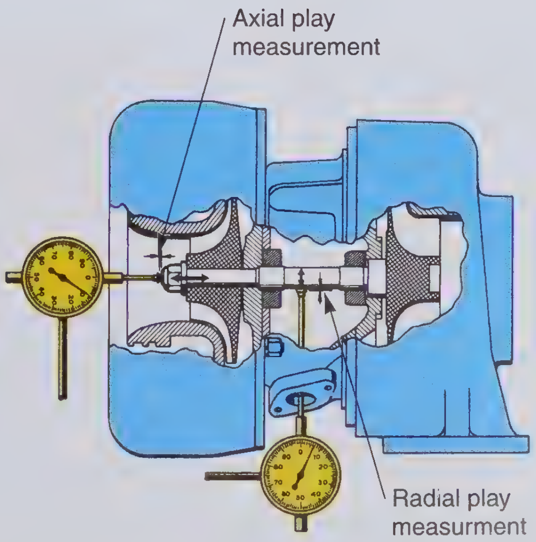

Figure 28-29. A dial indicator can be used to check radial and axial play of turbo shaft. If not within specifications, replace the unit. (Waukesha)

Caution!
Never use a hard metal object or sandpaper to remove carbon deposits from the turbine wheel. If you gouge the wheel, it can vibrate and destroy the turbo when its spins up to speed. Only use a soft wire brush and solvent to clean the turbo wheels.

Installing a New Turbocharger

Many turbocharger problems are not repaired in the field, **Figure 28-30.** Most technicians install a new or rebuilt unit. When installing a turbocharger, you should:

- Make sure the new turbo is the correct type. Compare part numbers.
- Use new gaskets and seals.
- Torque all fasteners to specifications.
- If needed, change the engine oil and flush the oil lines before starting the engine.
- If the failure was oil related, check the oil supply pressure in the feed line to the turbocharger.

Waste Gate Service

An inoperative waste gate can either cause too much or too little boost pressure. If the waste gate is stuck open, the turbocharger will not produce boost pressure and the engine will lack power. If the gate is stuck closed, detonation and engine damage can result from excessive boost.

Before replacing the waste gate, always check other parts. Check the knock sensor and the ignition timing. Make sure the vacuum pressure lines are all connected properly.

Follow service manual instructions when testing or replacing a waste gate. As shown in **Figure 28-31,** waste gate removal is relatively easy. Simply unbolt the fasteners, remove the lines, and lift the unit off the engine. Many manuals recommend waste gate replacement, rather than in-shop repairs.

Superchargers

A ***supercharger*** is a compressor or blower driven by a belt, chain, or gears. Unlike a turbocharger, it is not

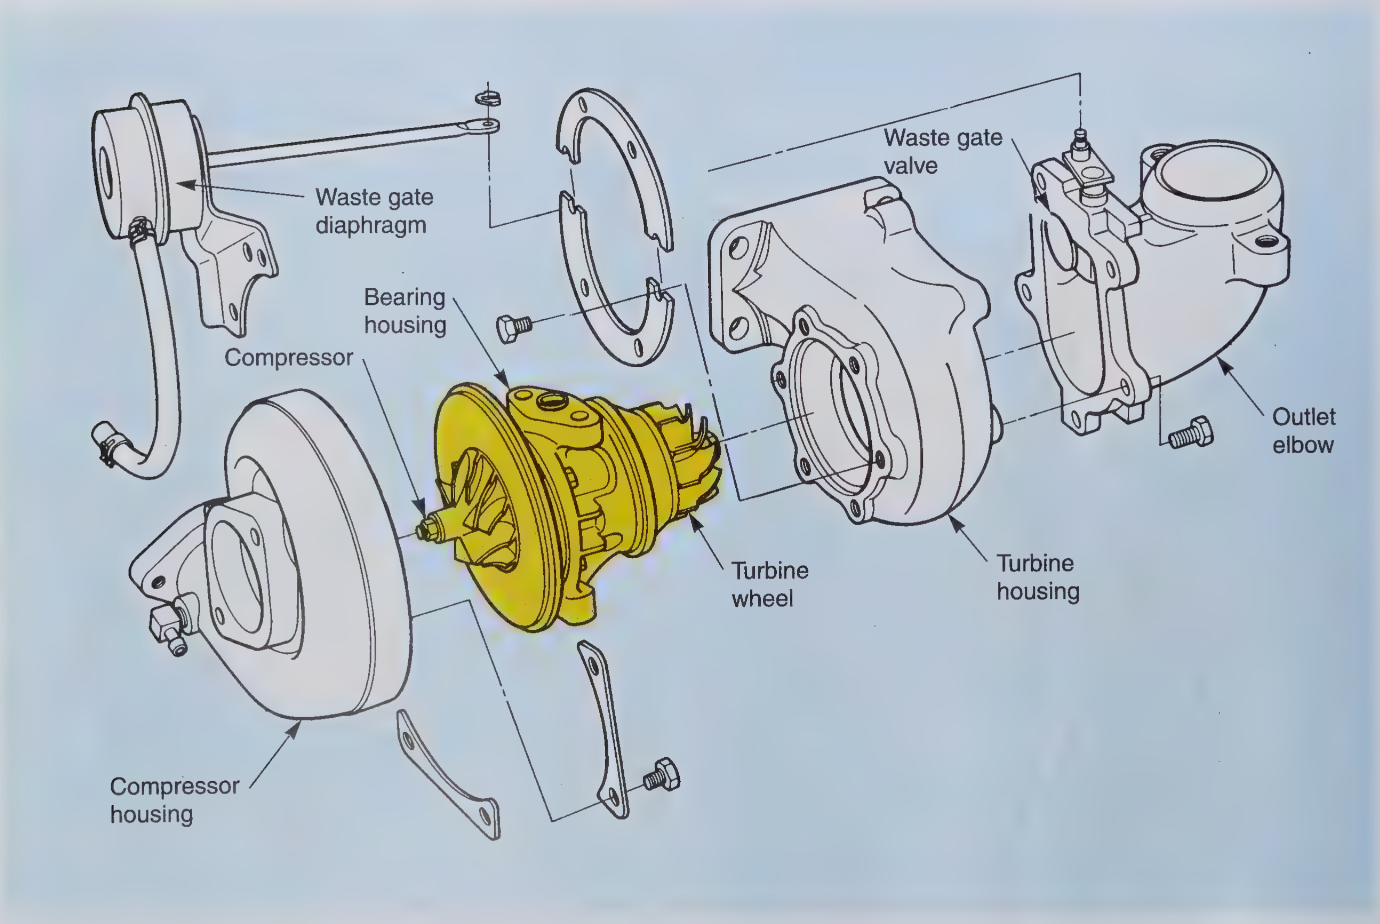

Figure 28-30. Exploded view of a turbocharger. Only external parts are serviceable. Turbine-compressor wheel is a very precise, balanced assembly. The slightest nick or chip on a blade can cause the unit to explode in service. (Ford)

driven by engine exhaust gases. Most passenger car superchargers are driven by a belt on the front of the engine. See **Figure 28-32.**

The ***supercharger belt*** drives the rotors inside the supercharger. As the rotors turn, they compress the air inside the housing and force the air, under pressure, into the engine intake manifold. See **Figure 28-33.**

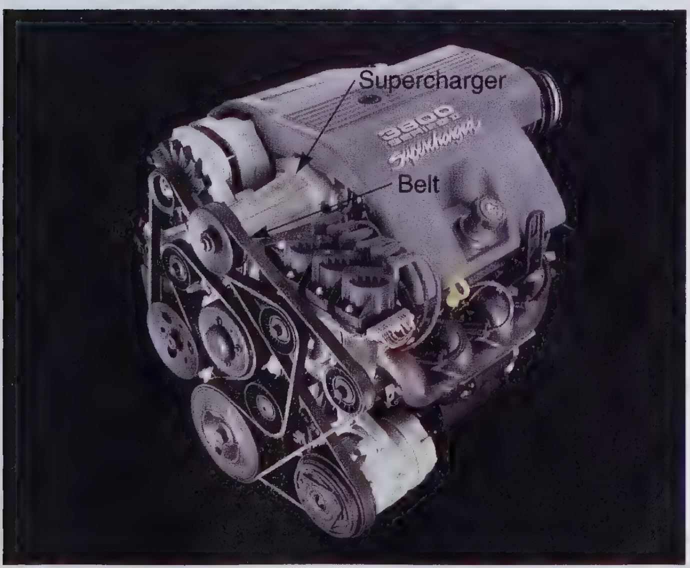
Figure 28-31. The waste gate normally bolts to the side of the turbo housing. A linkage rod connects the diaphragm with the valve mechanism. Also note the seal that prevents tampering with boost setting. Although overboost will increase power, it can also cause engine damage. (Saab)



Supercharger
Belt

Figure 28-32. A supercharged engine provides added acceleration for entering highway ramps and passing other vehicles. The engine must be modified with a stronger reciprocating assembly (crankshaft, connecting rods, and pistons) to withstand the power increase without part failure. (General Motors)

An ***electromagnetic clutch*** is sometimes used to disengage the drive belt from the blower. It works like an air-conditioning compressor clutch to save energy when additional power is not needed. See **Figure 28-34.** An

Electromagnetic clutch
Inlet
Blower housing

Figure 28-34. The supercharger is normally driven by belt running up from the engine crankshaft pulley. An electric clutch can be used to turn the blower on and off as needed. For example, the blower might only engage at full throttle when there is demand for more engine power. (Toyota)

intercooler, explained earlier, is commonly used between the supercharger outlet and the engine to cool the air and increase power (cool charge of air carries more oxygen needed for combustion).

Superchargers have the advantage of not suffering from turbo lag. A supercharger will instantly produce boost pressure at low engine speeds because it is mechanically linked to the engine crankshaft. This low-speed power and instant throttle response is desirable in a passenger car when passing other vehicles and when entering interstate highways.

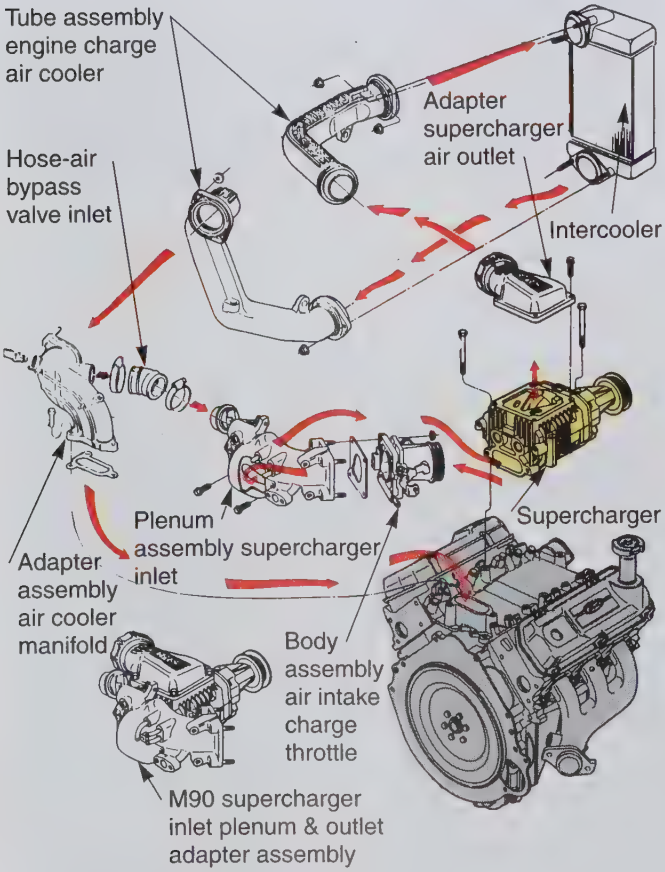
Figure 28-35 shows the major parts included in a supercharger system.

Supercharger Types

There are three basic types of superchargers:

- Centrifugal supercharger.
- Rotor (Rootes) supercharger.
- Vane supercharger.

These types are shown in **Figure 28-36.** Note the differences in construction and operation.



Tube assembly engine charge air cooler

Supercharger Service

A faulty supercharger will exhibit many of the same symptoms described for a faulty turbocharger: lack of power, blue engine smoke, abnormal noises, etc.

If the engine lacks power, measure boost pressure by connecting a pressure gauge to a fitting on the intake manifold. If boost is low, check the ***bypass actuator,*** which controls the supercharger boost pressure, **Figure 28-37.**

A bypass actuator that is stuck open can lower boost pressure and power. If the bypass is held closed and the boost will still not reach its maximum, suspect internal rotor or housing wear in the supercharger.

To isolate noises, place a stethoscope on the supercharger. Check for bearing noise at each end of the housing. Internal noises usually require supercharger removal and rebuilding, **Figure 28-38.**

A supercharger rebuild generally involves replacing all bearings and seals. You must also measure rotor lobe wear and internal housing wear. The clearances between the rotors and housing must be within specifications. If parts are worn, most shops simply install a new or rebuilt supercharger.

Scanning a Supercharging System

With vehicles equipped with onboard diagnostic systems, use a scan tool to help find supercharging system problems. The scan tool will show any diagnostic trouble codes and will also output system electrical values. You can check the operation of the knock sensor, manifold pressure sensor, and other devices that control supercharging.

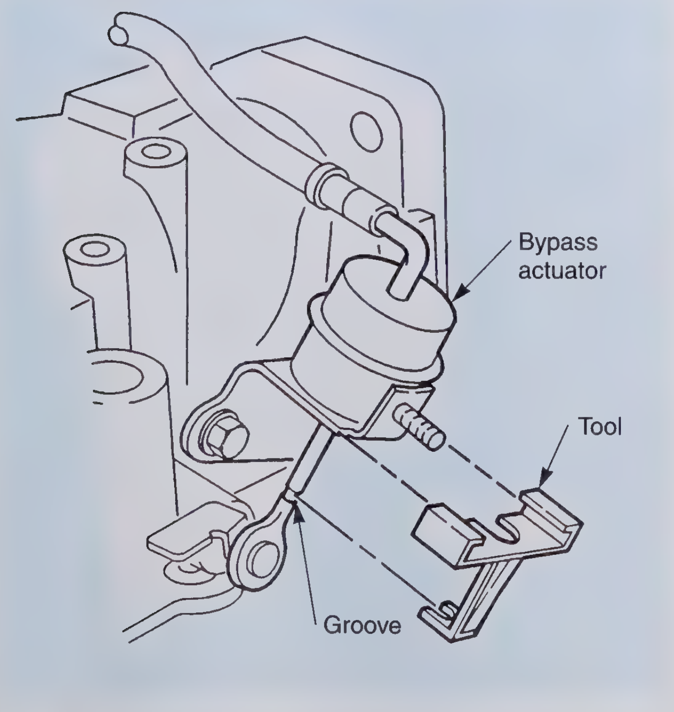

Figure 28-37. Supercharger bypass actuator serves the same purpose as a waste gate on a turbocharging system. When supercharger boost pressure reaches a maximum value, air pressure overcomes spring tension to bypass extra air, limit boost, and prevent engine damage. (General Motors)

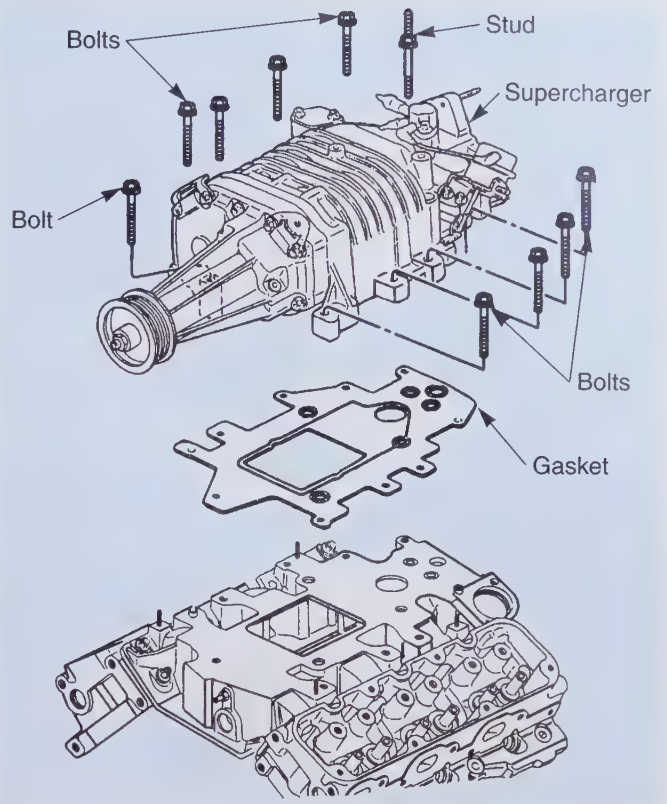

Figure 28-38. If your tests find a supercharger problem, remove it for replacement or repairs. Simply remove the belt and any parts (hoses, brackets, wires) that prevent supercharger removal. After removal of all bolts, light prying will free the supercharger from its gasket. (General Motors)

Accident Report

A technician was working on a supercharged passenger car engine. He was leaning in over the fender looking for problems when his feet slipped out from under him. His hand accidentally slipped between the supercharger belt and its pulley. Even though the engine was idling slowly, the pulley severely cut three of his fingers.

Doctors were able to save the technician's fingers, but he never regained full use of his hand. Although the technician still works on cars, he takes safety much more seriously.

Summary

- An exhaust system quiets engine operation and carries exhaust fumes to the rear of the vehicle.
- An exhaust manifold connects the cylinder head exhaust ports to the header pipe.
- The header pipe is steel tubing that carries exhaust gases from exhaust manifold to catalytic converter or muffler.

- A catalytic converter is a device for removing pollutants from engine exhaust.
- The intermediate pipe is tubing sometimes used between the header pipe and muffler or the catalytic converter and muffler.
- A muffler is a metal chamber for damping pressure pulsations to reduce exhaust noise.
- Heat shields are metal plates that prevent exhaust heat from transferring into another object.
- A supercharger is an air pump that increases engine power by pushing a denser air-fuel charge into the combustion chambers.
- A normally aspirated engine, called an atmospheric engine, uses atmospheric pressure to push air into the engine.
- In the field, the term "supercharger" generally refers to a blower driven by a belt, gears, or chain.
- A turbocharger is an exhaust-driven fan or blower that forces air into the engine under pressure.
- Turbo lag refers to a short delay before the turbo develops sufficient boost.
- A turbocharger intercooler is an air-to-air heat exchanger that cools the air entering the engine.
- The supercharger belt drives the rotors inside the supercharger.

Review Questions—Chapter 28

Please do not write in this text. Place your answers on a separate sheet of paper.

1. An exhaust system _____ engine operation and carries _____ _____ to the rear of the car.

Match the following exhaust system parts with their definition.

2. _____ Heat shield.
3. _____ Catalytic converter.
4. _____ Intermediate pipe.
5. _____ Hangers.
6. _____ Header pipe.
7. _____ Tailpipe.
8. _____ Muffler clamp.
9. _____ Exhaust manifold.
10. _____ Muffler.

A. U-bolt for connecting parts of exhaust system.
B. Tubing that connects exhaust manifold to rest of system.
C. Chamber for damping out pressure pulsations.
D. Carries exhaust from muffler to rear of car body.
E. Connects cylinder head exhaust ports to header pipe.
F. Prevents heat from transferring into other objects.
G. Connects exhaust manifold to tailpipe.
H. Device for removing pollutants from exhaust.
I. Pipe between catalytic converter and muffler.
J. Connects exhaust system to underside of car body.

11. Define the term "exhaust back pressure."
12. A dual exhaust system is commonly used on small, high-fuel-economy engines. True or False?
13. An exhaust _____ _____ _____ forces hot exhaust gases to flow into the intake manifold to aid cold weather starting.
14. When is exhaust system service commonly needed?

15. List fourteen rules to remember when servicing an exhaust system.
16. What is a normally aspirated engine?
17. A(n) _____ is an air pump that increases engine power by pushing a denser air-fuel charge into the combustion chambers.
18. Explain the term "turbocharger."
19. The term "supercharger" generally refers to a blower driven by a(n) _____, _____, or _____.
20. List and explain the six basic parts of a turbocharger.
21. A(n) _____-_____ turbocharger has the turbo located before the carburetor or throttle body.
22. A turbocharger can operate at speeds up to _____ rpm.
23. _____ _____ refers to the short delay before the turbo develops sufficient boost.
24. A waste gate limits the minimum amount of boost produced by the turbocharger. True or False?
25. What could happen if a waste gate did not open?
26. List seven engine modifications commonly found on a turbocharged engine.
27. Which of the following is *not* a recommended practice when servicing a turbocharging system?
    (A) Inspect vacuum and oil lines to turbo and waste gate.
    (B) Remove carbon from turbo compressor with gasket scraper.
    (C) Use regulated, low-pressure air hose to check waste gate diaphragm leakage and operation.
    (D) Use pressure gauge to measure boost pressure.
    (E) Use stethoscope to listen for bad turbo bearings.
28. A turbocharger was badly damaged because of excess bearing and shaft wear. Technician A says that a new unit should be installed and that oil pressure to the turbo should be checked. Engine oil should be changed after a short break-in period. Technician B says that the oil should be drained and all lines should be flushed before installing the new turbocharger. Oil pressure to the unit should also be checked. Who is correct?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
29. An inoperative turbocharger waste gate can cause:
    (A) high boost pressure.
    (B) low boost pressure.
    (C) detonation.
    (D) All of the above.
30. Which of the following is *not* a type of supercharger?
    (A) Vane.
    (B) Gear.
    (C) Rotor.
    (D) Centrifugal.

ASE-Type Questions

1. Each of these is a major part of an exhaust system *except:*
    (A) muffler.
    (B) hangers.
    (C) flyweights.
    (D) header pipe.
2. Which of the following connects the right and left side header pipes?
    (A) Tailpipe.
    (B) Main pipe.
    (C) Intermediate pipe.
    (D) Crossover pipe.
3. Which of these is used to reduce the amount of exhaust pollutants entering the atmosphere?
    (A) Heat shields.
    (B) Catalytic converter.
    (C) Pyrex thermal packing.
    (D) Cylinder head exhaust ports.
4. Which of the following turbocharger parts passes through the center of the turbo housing?
    (A) Turbo shaft.
    (B) Turbine wheel.
    (C) Bearing housing.
    (D) Compressor wheel.
5. The delay before a turbo develops sufficient pressure is known as:
    (A) turbo lag.
    (B) turbo boost.
    (C) turbo bearing.
    (D) boost pressure.

6. Which of the following limits the maximum amount of boost pressure developed by the turbocharger?
   (A) *Diaphragm.*
   (B) *Waste gate.*
   (C) *Compressor.*
   (D) *Sealing rings.*
7. Technician A believes a turbocharged engine will need a higher compression ratio to withstand an increase in horsepower. Technician B feels the engine will no longer need a knock sensor if horsepower is increased. Who is right?
   (A) *A only.*
   (B) *B only.*
   (C) *Both A and B.*
   (D) *Neither A nor B.*
8. Which of the following helps an on-board computer keep the ignition timing advanced as much as possible?
   (A) *Diaphragm.*
   (B) *Control rod.*
   (C) *Knock sensor.*
   (D) *All of the above.*
9. Vibration and noise in a turbocharging system is a result of:
   (A) *damaged turbine.*
   (B) *leaking shaft seals.*
   (C) *inadequate boost pressure.*
   (D) *Any of the above.*
10. When installing a turbo, each of these is a rule to remember *except:*
    (A) *check and flush oil lines.*
    (B) *check and change engine oil.*
    (C) *torque all fasteners to specifications.*
    (D) *reuse good gaskets and seals.*

Activities—Chapter 28

1. Research the internal combustion process and produce a cutaway sketch of an exhaust system. Use it to explain why high back pressure will reduce engine power.
2. Using knowledge of atmospheric pressure, demonstrate to the shop class why a turbocharger or a supercharger will increase engine power.
3. Collect literature from dealerships on turbocharged and non-turbocharged engines. Develop a table of horsepower-to-displacement ratios. (This can be done by dividing the rated horsepower by the number of cubic inches or liters of displacement for each engine.) Draw up a report of your findings and present them to the class.

Exhaust System Diagnosis

Condition	Possible cause	Correction
Excessive exhaust noise (under hood).	1. Damaged exhaust manifold. 2. Manifold to cylinder head leak. 3. EGR valve leakage: (a) EGR valve to manifold gasket. (b) EGR valve to EGR tube gasket. (c) EGR tube to manifold tube nut. 4. Exhaust flex joint. (a) Spring height, installed not correct. (b) Exhaust sealing ring defective. 5. Pipe and shell noise from front exhaust pipe.	1. Replace manifold. 2. Tighten manifold and/or replace gasket. 3. (a) Tighten nuts or replace gasket. (b) Tighten nuts or replace gasket. (c) Tighten tube nut. 4. (a) Check spring height, both sides (specification is 32.5 mm, 1.28 inch) look for source of spring height variation if out of specification. (b) Inspect seal for damage on round spherical surface. If no damage is evident, check for exhaust obstruction causing high back pressure on heavy acceleration. 5. Characteristic of single wall pipes.
Excessive exhaust noise.	1. Leaks at pipe joints. 2. Burned or blown or rusted out muffler, tailpipe of exhaust pipe. 3. Restriction in muffler or tailpipe. 4. Converter material in muffler.	1. Tighten clamps at leaking joints. 2. Replace muffler or muffler tailpipe or exhaust pipe. 3. Remove restriction, if possible or replace as necessary. 4. Replace muffler and converter assemblies. Check fuel injection and ignition systems for proper operation.
Exhaust system mechanical noise.	1. Improperly aligned exhaust system. 2. Support brackets loose, bent, or broken. 3. Incorrect muffler or pipes. 4. Baffle loose in muffler. 5. Manifold heat control valve rattles. 6. Worn engine mounts. 7. Damaged or defective catalytic converter.	1. Align system. 2. Tighten or replace brackets. 3. Install correct muffler or pipes. 4. Replace muffler. 5. Replace thermostatic spring. 6. Replace engine mounts. 7. Repair or replace converter.
Engine lacks power.	1. Clogged muffler. 2. Clogged or kinked exhaust or tailpipe. 3. Muffler or pipes too small for vehicle. 4. Catalytic converter clogged or crushed shut.	1. Replace muffler. 2. Replace pipe. 3. Install muffler and pipes of the correct size and type. 4. Replace with new converter.

38. Sound Systems, Power Options

Almost every system in a modern vehicle uses some type of electric or electronic component. Electronic ignition, electronic fuel injection, computerized engine management systems, "smart" air bag systems, collision avoidance systems, anti-lock brakes, and other advanced systems require technicians skilled in electricity and electronics. Even specialized technicians need a background in electricity and electronics to fix today's vehicles.

This section details the operation, diagnosis, and repair of the major electrical systems. It starts with the battery, the source of initial electrical energy, and progresses through the starting, charging, ignition, and other systems.

Study this information carefully. A technician who is well versed in electricity and electronics is in high demand. The information in this section will help you pass ASE Test A6, *Electrical/Electronic Systems.*

29

Automotive Batteries

After studying this chapter, you will be able to:

- Explain the operating principles of a lead-acid battery.
- Describe the basic parts of an automotive battery.
- Compare conventional and maintenance-free batteries.
- Explain how temperature and other factors affect battery performance.
- Describe safety practices that should be followed when working with batteries.
- Correctly answer ASE certification test questions that require a basic knowledge of automotive batteries.

Earlier textbook chapters briefly introduced battery operation and electrical fundamentals. This chapter will build on this knowledge by discussing automotive batteries in more detail. It will prepare you to learn about battery service, as well as charging and starting systems.

Battery Principles

An ***automotive battery*** is an electrochemical device that produces and stores electricity. A cutaway of such a battery is shown in **Figure 29-1.** A battery produces direct current (***dc***) electricity, which flows in only one direction.

When ***discharging*** (current flowing out of the battery), the battery changes chemical energy into electrical energy. In this way, it releases stored energy.

During ***charging*** (current flowing into the battery from the charging system), the battery converts electrical energy to chemical energy. The battery can then store this energy until needed.

Battery cycling refers to repeated charging-discharging events. In extreme cases, the battery is almost fully discharged by sitting or cranking-current draw and is recharged once the engine is started. Repeated ***deep cycling*** (going from a very low charge to a full charge) can shorten battery service life.

Basic Battery Cell

A simple ***battery cell*** consists of a negative plate, positive plate, container, and electrolyte (battery acid). Look at **Figure 29-2.**

The ***battery plates*** are made of lead and lead oxide. These act as dissimilar (unlike) metals. The container is usually plastic to resist corrosion. The electrolyte is a mixture of sulfuric acid and water.

If a ***load*** (current-using device) is connected to our simple battery cell, current will flow through the load. If

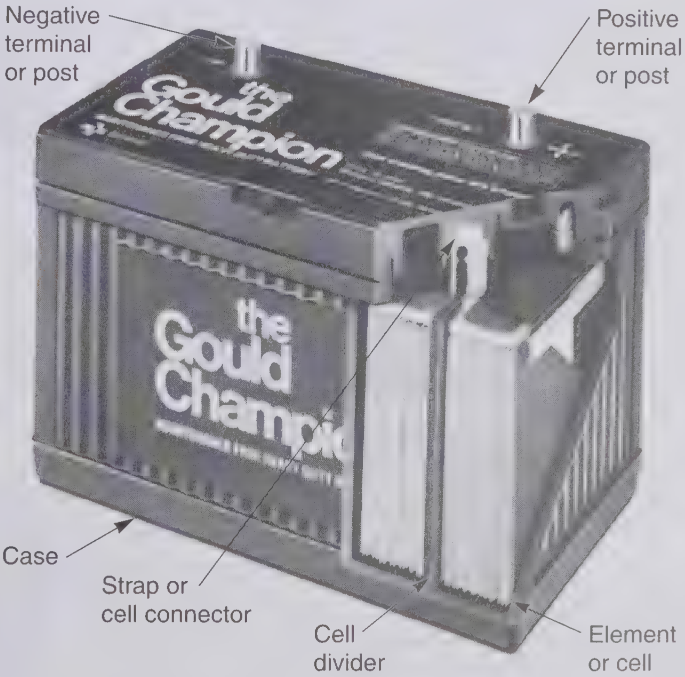

Figure 29-1. Before learning how a battery works, study in detail its basic parts. Note part names and locations. (Gould)

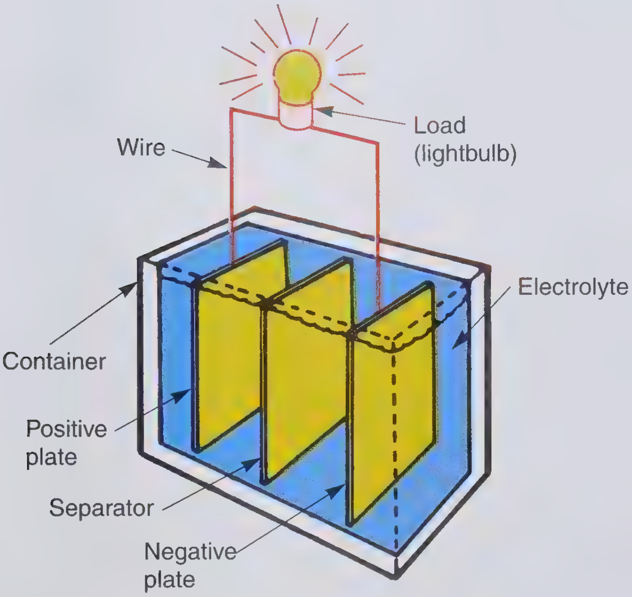
the load is a lightbulb, as in **Figure 29-2,** the bulb will glow because of electron movement.



Wire
Load (lightbulb)
Electrolyte
Container
Positive plate
Separator
Negative plate

Figure 29-2. A simple lead-acid battery cell. The positive and negative plates are kept apart by a separator. An electrolyte causes a chemical reaction between plates, producing current flow through the circuit. One cell like this would produce 2.1 volts.

Battery Cell Action

Figure 29-3 shows the basic chemical-electrical action inside a battery cell. When the cell is being charged, the alternator causes free electrons (negative charges) to be deposited on the negative (–) plate. This causes the plates to have a difference in potential (electrical pressure, or voltage).

When a load is connected across the terminals, there is a current (flow of electrons) to equalize the difference in charges on the plates. The excess electrons move from the negative plate to the positive plate.

Battery Functions

A vehicle battery has several important functions. It must:

- Operate the starting motor, ignition system, electronic fuel injection system, and other electrical devices during engine cranking and starting.
- Supply all the electrical power for the vehicle whenever the engine is not running.
- Help the charging system provide electricity when current demands exceed the output limit of the charging system.

Charged

Figure 29-3. Basic battery cycling. (DaimlerChrysler)

- Act as a capacitor (voltage stabilizer) that smoothes current flow through the electrical system.
- Store energy (electricity) for extended periods.

Imagine the following sequence of events: You are sitting in your car with the radio on, but the engine is not running. The battery is supplying the electricity to operate the radio and any indicator lights. It is slowly discharging.

When you start the engine, the battery provides a tremendous amount of current. This energy operates the starting motor and essential engine systems. This, too, drains current out of the battery.

As soon as the engine starts, the charging system takes over. It recharges the battery while feeding current to the electrical units in the car.

If the load becomes too much for the charging system (engine idling slowly and all accessories on, for example), the battery may also feed current into the electrical system.

Battery Construction

Automobile batteries are built to withstand severe vibration, extreme temperatures, corrosive chemicals, high current discharge, and prolonged periods without use. To properly test and service batteries, you must understand battery construction.

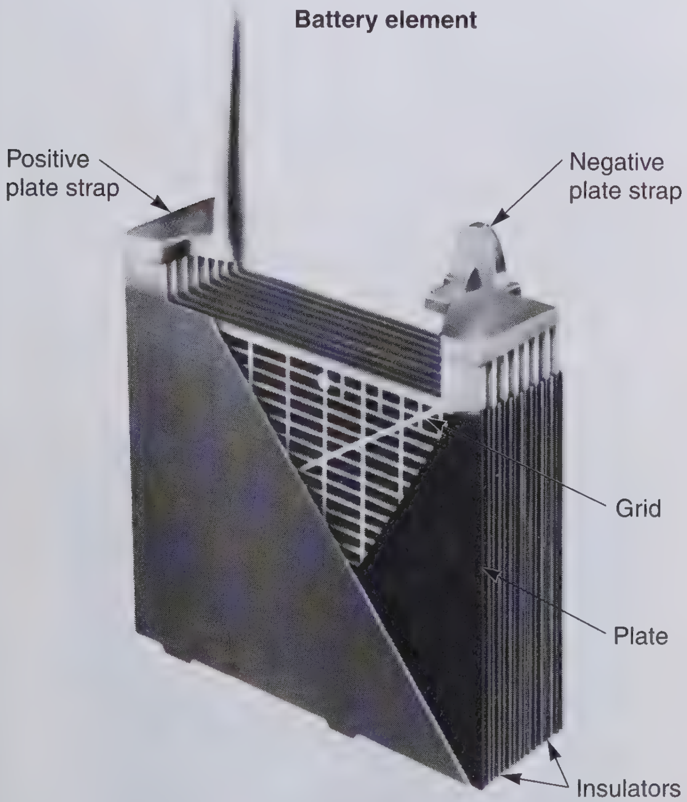

Figure 29-4. A battery element is made up of a positive plate group, negative plate group, separators, and straps. Most auto batteries have six elements. The elements fit into the battery case. (Gould)

Battery Element

A ***battery element*** is made up of positive plates, negative plates, straps, and separators. The element fits into a cell compartment in the battery case. Refer to **Figure 29-4.**

The ***battery plates*** are made of a grid (stiff mesh framework) coated with porous lead. Shown in **Figure 29-4,** several plates are needed in each cell to provide enough battery power.

Lead battery straps, or *connectors*, run along the upper part of the case to connect the plates. One strap connects the negative plates to form a negative plate group. Another lead strap connects the positive plates, forming the positive plate group. The battery terminals (top posts or side terminals) are constructed as part of one end of each strap. Look at **Figure 29-4**.

The chemically active material in the negative plates is porous lead, **Figure 29-4.** The active material on the positive plates is lead peroxide. Calcium or antimony is normally added to the lead to increase battery performance and decrease ***gassing*** (acid fumes forming during chemical reaction).

Since the lead on the plates is porous, like a sponge, the battery acid easily penetrates the material. This aids the chemical reaction and the production of electricity.

Separators fit between the battery plates to keep them from touching each other and shorting. The separators are made of insulating material. They have openings that allow free circulation of the electrolyte around the battery plates.

Battery Case, Cover, and Caps

The ***battery case,*** usually made of high-quality plastic, holds the elements and electrolyte, **Figure 29-5.** The case must withstand extreme vibration, temperature change, and the corrosive action of the battery acid. Dividers in the case form individual containers for each element. A container and its element make up one cell.

The ***battery cover*** is bonded to the top of the battery case. It seals the top of the case. There is an opening above each battery cell for battery caps or a cell cover. Refer to **Figure 29-5.**

Battery caps snap into the holes in the battery cover. They keep electrolyte from splashing out of the battery. The caps also serve as spark arrestors (keep sparks or flames from igniting gases inside battery). Maintenance-free batteries have a large cover that is not removed during normal service.

Warning!
Hydrogen gas can collect at the top of a battery. If this gas is exposed to a flame or spark, it can explode!

Electrolyte (Battery Acid)

Electrolyte, often called ***battery acid,*** is a mixture of sulfuric acid and distilled water, **Figure 29-6.** Electrolyte is poured into each cell until plates are covered.

Distilled water is used in batteries because it does not contain many of the impurities found in tap water. These impurities can contaminate the battery plates and reduce efficiency.

Warning!
Avoid having electrolyte come in contact with your skin or eyes. The sulfuric acid in the electrolyte can cause serious skin burns or even blindness.

Battery Charge Indicator

A ***battery charge indicator,*** also called a ***battery eye*** or ***test indicator,*** shows the general charge condition of the battery. One is pictured in **Figure 29-7.**

The charge indicator changes color as the level of battery charge changes. For example, the indicator may be green with the battery fully charged. It may turn black

when the battery is discharged or yellow when the battery needs replacement.

Battery Terminals

Battery terminals provide a means of connecting the battery plates to the car's electrical system. Either two round posts or two side terminals can be used, as shown in **Figure 29-8.**

Battery posts are round metal terminals that extend through the top of the battery cover. They serve as male connections for female battery cable ends.

The ***positive post*** is larger than the negative post. It may be marked with red paint and a positive (+) symbol. The ***negative post*** is smaller and may be black or green in color. It normally has a negative (–) symbol on or near it.

Side terminals are electrical connections located on the side of the battery. They have female threads that accept a special bolt on the battery cable end. Side terminal polarity is identified by positive and negative symbols on the case.

Battery Voltage

Battery ***open circuit*** (no load) ***cell voltage*** is 2.1 volts, often rounded to 2 volts. Since the cells in a battery are connected in series, battery voltage depends on the number of cells. Refer to **Figure 29-9.**

A 12-volt battery has six cells, which produce an open circuit voltage of 12.6 volts. Modern vehicles use a 12-volt battery and 12-volt electrical system. Older vehicles are designed to use 6-volt batteries. See **Figure 29-9.**

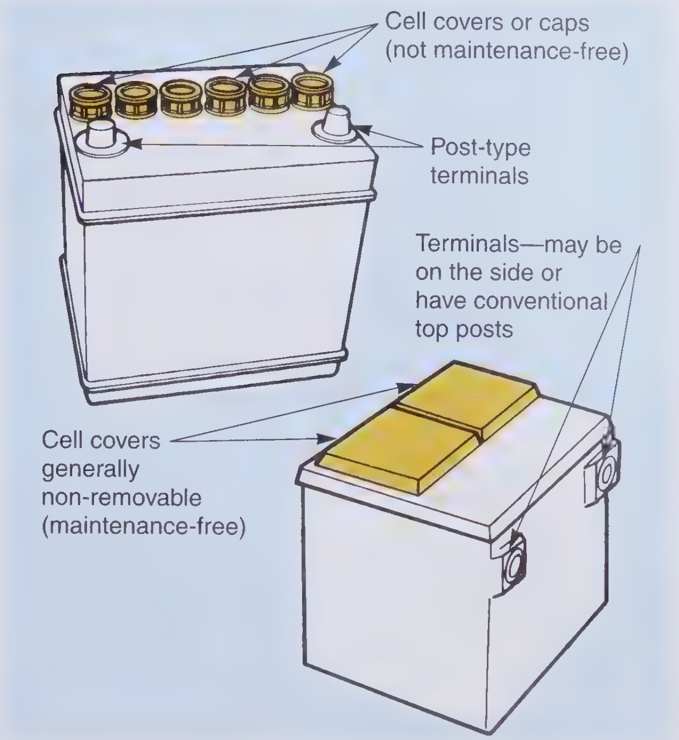
Some cars with diesel engines use two 12-volt batteries connected in parallel. When two batteries are in parallel, their output voltage stays the same, but their current output increases. Dual batteries may be needed to crank and start a compression-ignition diesel engine.

Caution!
When two batteries are connected in *series,* their output voltage doubles. Keep this in mind when working with batteries. Two 12-volt batteries connected in series produces 24 volts, which could damage electrical devices.

Battery Cables

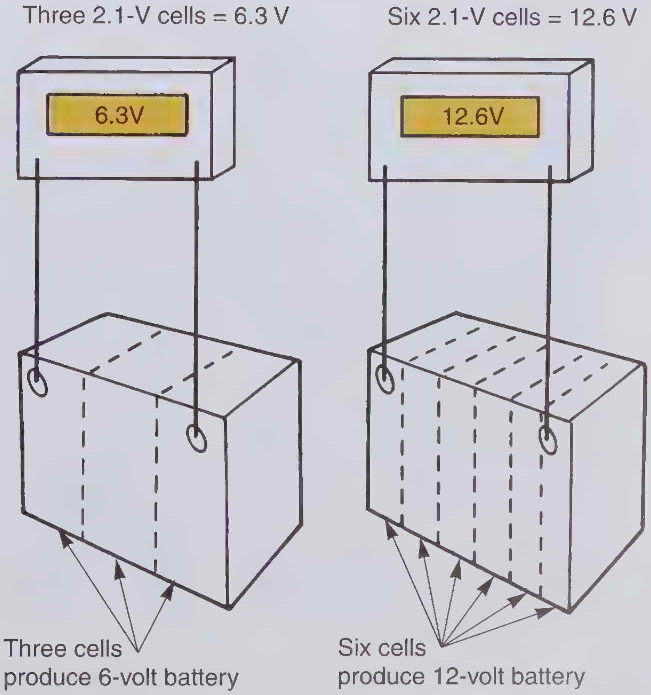
Battery cables are large wires that connect the battery terminals to the vehicle's electrical system.

The ***positive cable*** is normally red and fastens to the starter solenoid (introduced in Chapter 1). The ***negative battery cable*** is usually black and connects to ground on the engine block. Various types of battery cables are



Cell covers or caps
(not maintenance-free)
Post-type terminals
Terminals—may be on the side or have conventional top posts
Cell covers generally non-removable (maintenance-free)

Figure 29-8. Study the differences between batteries. Maintenance-free batteries do not have vent caps. Post or side terminals may be used on conventional or maintenance-free batteries. (DaimlerChrysler)



Three 2.1-V cells = 6.3 V
Six 2.1-V cells = 12.6 V
6.3V
12.6V
Three cells produce 6-volt battery
Six cells produce 12-volt battery

Figure 29-9. Three cells connected in series produce 6.3 volts. The three cells are rated as, or called, a 6-volt battery. A more common unit of six cells produces 12.6 volts, or a 12-volt battery.

pictured in **Figure 29-10.** Note that ground cables do not always use insulation.

Sometimes, the negative battery cable will have a body ground wire, which ensures that the vehicle body is grounded. See **Figure 29-11.** If this wire does not make a good connection, components grounded to the car body may not operate properly.

Battery Tray and Retainer

A ***battery tray*** and ***retainer*** hold the battery securely in place. They keep the battery from bouncing around during vehicle movement. It is important that the tray and retainer be tight and in good condition to prevent battery damage. Look at **Figure 29-12.**

In many late-model vehicles, the battery tray houses a ***battery temperature sensor.*** This sensor monitors battery temperature The engine control module uses data from this sensor to determine when to vary the battery charging rate.

The ***battery hold-down*** usually consists of a special bracket and fasteners that secure the battery to its tray. The hold-down must be tight enough to prevent battery movement.

Battery heat shields are designed to keep excess engine heat from damaging the battery. They usually fit over the battery or between the engine and battery case. Always reinstall battery heat shields to ensure normal battery life. See **Figure 29-13.**

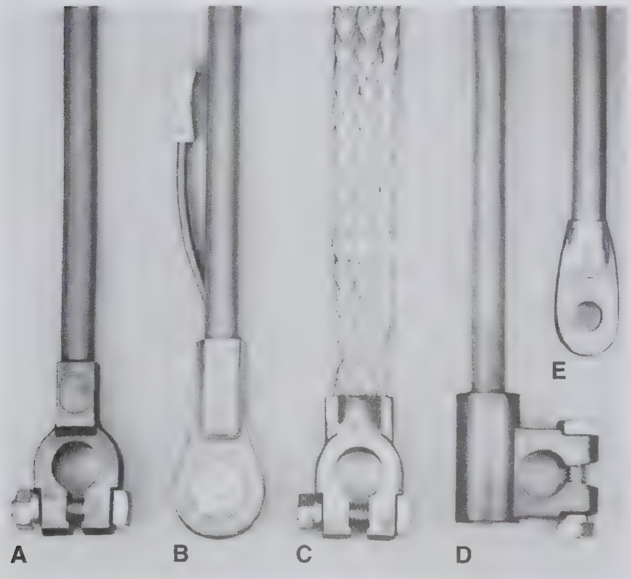


Figure 29-10. Battery cable types. A—Post-type battery cable. B—Side terminal battery cable with pigtail for ground or accessory connection. C—Braided ground cable. D—90° post-type cable. E—Solenoid-to-starter cable. Note the large conductor size for carrying a large amount of current to the starter. (Belden)

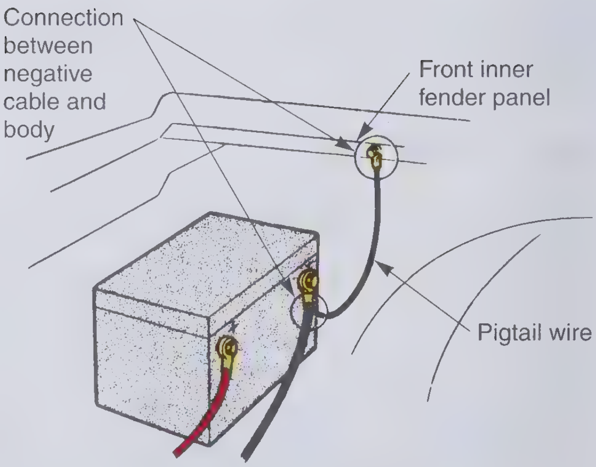

Figure 29-11. Note the cable connections to the battery. The negative cable grounds on the engine block. The positive cable connects to the electrical system. A pigtail grounds the car body to battery negative. (Sun)

Wet- and Dry-Charged Batteries

There is no difference in the materials used in wet- and dry-charged batteries. The difference is in how the batteries are prepared for service.

With a ***wet-charged battery,*** the battery is filled with electrolyte and charged at the factory. The battery is then tested and placed in stock, ready for service.

A ***dry-charged battery*** contains fully charged elements but does not contain electrolyte. It leaves the

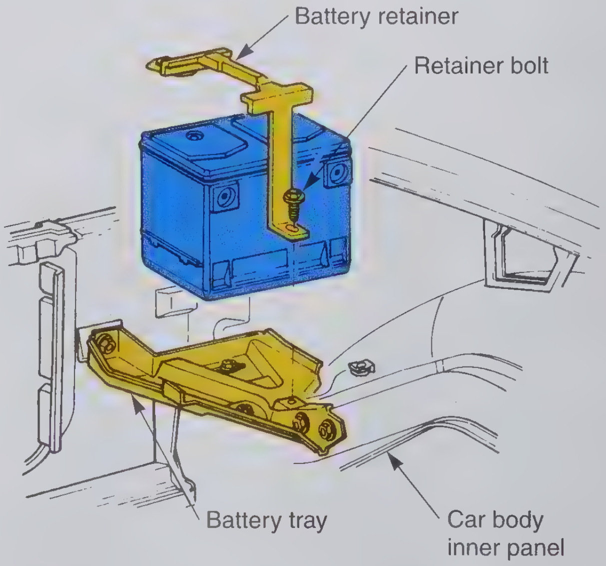

Figure 29-12. Battery tray and retainer hold the battery securely in place. The tray usually mounts on the inner body panel. (Cadillac)

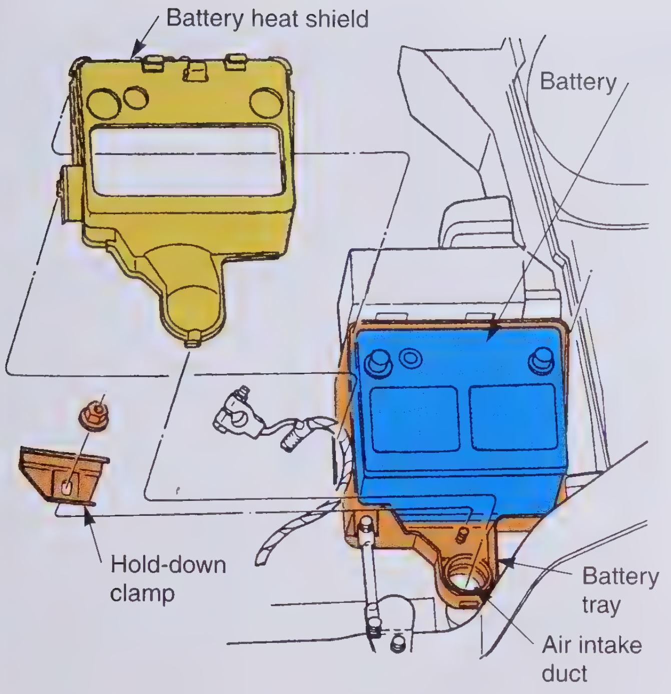

Figure 29-13. A battery heat shield is used to protect the battery from excess engine heat. Note the battery tray in this particular vehicle contains an air intake duct, which routes outside air to the area between the heat shield and the battery case. (DaimlerChrysler)

factory in a dry state. Before use, this type of battery is filled with electrolyte. A dry-charged battery is commonly used because it has a much longer shelf life than a wet-charged battery.

Note!
Activation of a dry-charged battery is covered in Chapter 30, *Battery Testing and Service.*

Maintenance-Free Battery

A ***maintenance-free battery*** is easily identified because it does not use removable filler caps. The tops of the battery cells are covered with a large, snap-in cover. Calcium is used to make the battery plates, so water does not have to be periodically added to the electrolyte.

The calcium in the plates reduces the production of battery gases. As a result, battery gas does not carry as much of the chemicals out of the battery. This increases battery service life and decreases service requirements.

Battery Ratings

Battery ratings are set according to national test standards for battery performance. They let the technician and consumer compare the cranking power of one battery to another.

The two most common methods of rating lead-acid storage batteries are the cold cranking rating and reserve capacity rating. These ratings were developed by the Society of Automotive Engineers (SAE) and the Battery Council International (BCI).

Battery Cold Cranking Rating

The ***cold cranking rating*** determines how much current (in amperes) the battery can deliver for 30 seconds at 0°F (–18°C) while maintaining terminal voltage of 7.2 volts, or 1.2 volts per cell. This rating indicates the battery's ability to crank a specific engine (based on starter current draw) at a specified temperature.

For example, one auto manufacturer recommends a battery with 305 cold cranking amps for a small 4-cylinder engine but a battery with 450 cold cranking amps for a larger V-8 engine. A more powerful battery is needed to handle the heavier starter current draw of the larger engine.

A ***battery watt rating*** is another battery rating. It is the equivalent of the cold cranking rating. Remember that watts are a measure of power equal to voltage multiplied by current.

Battery Reserve Capacity Rating

The ***reserve capacity rating*** is the time needed to lower battery terminal voltage below 10.2 volts (1.7 volts per cell) at a discharge rate of 25 amps. This is with the battery fully charged and at 80°F (27°C).

Reserve capacity will be given as a time interval in minutes. For example, if a battery is rated at 90 minutes and the charging system fails, the driver has approximately 90 minutes of driving time under minimum electrical load before the battery goes completely dead.

Battery Amp-Hour Rating

The ***amp-hour rating*** was once used to indicate battery power. It was a measurement of how much current the battery could produce for 20 hours at 80°F (27°C) with battery voltage staying above 10.5 volts.

Battery Temperature and Efficiency

As battery temperature drops, battery power is reduced. At low temperatures, the chemical action inside the battery is slowed. When cold, a battery will not produce as much current as when warm. This affects a battery's ability to start an engine in extremely cold weather. Also, when an engine is cold, the motor oil is very thick. This increases the amount of current needed to crank the engine with the starting motor.

Figure 29-14 shows a chart comparing battery efficiency and required starting power. Note that at 0°F (–18°C), a battery has only 40% of its normal cranking power. In addition, starter current draw will be up approximately 200% of its normal value. The engine could be very difficult to start on a cold morning. The battery, starter, and electrical connections must be in almost perfect condition.

Parasitic Loads

A ***parasitic load*** is any normal accessory circuit current draw present when all electrical devices are shut off. This load would include anything that requires a small current when the engine and ignition key are turned off (clock, alarm, etc.). This results in a parasitic load on the battery.

If a vehicle sits unused for prolonged periods, the parasitic load can drain the battery enough to prevent starting. A battery must be in good condition to withstand prolonged parasitic load.

Duff's Garage

Problem: A 2000 Chevrolet Monte Carlo is brought to the shop on a tow truck.

Diagnosis: Although the vehicle's owner is not present, Duff questions the tow truck driver about the nature of the problem. It seems that the owner was trying to jump start the vehicle when the battery exploded. Duff opens the hood and immediately sees evidence of the explosion. The top section of the battery case has been blown away, and acid has been thrown all over the engine compartment and onto the tops of the inner fenders, ruining the paint. Duff notes that both jumper cables are still connected to the terminals on the dead battery. He suspects that the final hookup to the discharged battery caused a spark, igniting the hydrogen gas around the battery case and causing an explosion. He takes the time to call his technicians over to the vehicle, explaining to them the importance of proper jumper cable hookup.

Duff calls the vehicle's owner with a repair estimate. The owner, happy that the car can be fixed, tells Duff to do whatever is necessary to repair the vehicle. Duff turns the repair over to the shop apprentice.

Repair: While wearing a full-face shield, a rubber apron, and rubber gloves, the apprentice disconnects the battery cable ends and removes the damaged battery. He places the battery in a trash bag for shipment to a battery recycling company.

The apprentice washes the engine compartment down with a solution of baking soda and water, paying special attention to the battery tray and the area around the battery. He pressure washes the engine compartment. Then he coats the exposed bare metal on the battery tray and inner fenders with self-etching primer. Finally, he paints the tray and fender wells with semi-gloss enamel.

After allowing the paint to dry, the apprentice installs a new battery. He starts the engine to check for problems and tests the charging system output. Confident that all the necessary repairs have been made, the apprentice calls the owner to inform him that the vehicle is ready to be picked up.

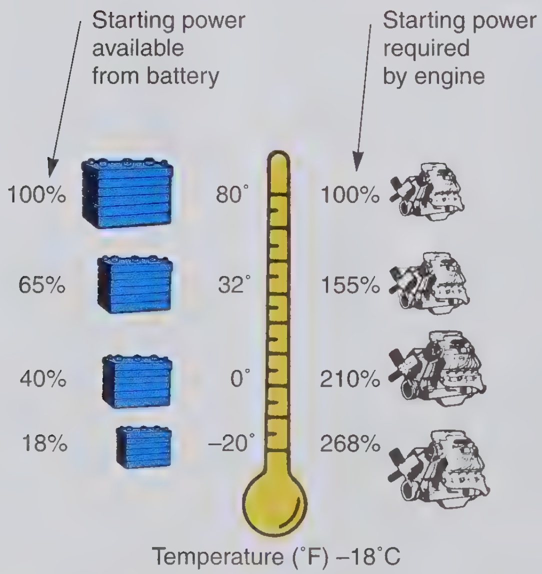

Figure 29-14. Temperature affects battery power and starter current draw. This is why engines crank slowly in very cold weather. (Champion Spark Plugs)

Summary

- An automotive battery is an electrochemical device for producing and storing electricity.
- The battery case, usually made of high quality plastic, holds the elements and electrolyte.
- Electrolyte, often called battery acid, is a mixture of sulfuric acid and distilled water.
- A 12-volt battery has six cells that produce an open circuit voltage of 12.6 volts.

- Battery cables are large wires that connect the battery terminals to the electrical system of the vehicle.
- A maintenance-free battery is easily identified because it does not use removable filler caps.
- The cold cranking rating determines how much current (in amperes) the battery can deliver for 30 seconds at 0°F (–18°C) while maintaining terminal voltage of 7.2 volts, or 1.2 volts per cell.
- The reserve capacity rating is the time needed to lower battery terminal voltage below 10.2 volts (1.7 volts per cell) at a discharge rate of 25 amps.
- A parasitic load includes any current draw present when all electrical devices are shut off.

Review Questions—Chapter 29

Please do not write in this text. Place your answers on a separate sheet of paper.

1. A(n) _____ _____ is an electrochemical device for producing and storing electricity.
2. Define the terms battery "discharging" and "charging."
3. Which of the following is *not* part of a basic battery cell?
   (A) Positive plate.
   (B) Negative plate.
   (C) Electrolyte.
   (D) Spark arrestors.
4. List five functions of a car battery.
5. Explain the function of a spark arrestor in an automotive battery.
6. _____ gas can collect around the top of batteries. If this gas is exposed to a flame or spark, it can _____ !
7. Electrolyte, also called battery acid, is a mixture of sulfuric acid and distilled water. True or False?
8. What is the purpose of a charge indicator or eye?
9. Describe the difference between battery posts and side terminals.
10. A 12-volt battery has _____ cells that produce an open circuit voltage of _____ volts.
11. Most modern vehicle's use 6-volt batteries. True or False?
12. The battery positive cable normally connects to the _____ _____ and the negative cable connects to _____ on the engine.
13. Explain the difference between a wet- and a dry-charged battery.
14. A(n) _____ battery is easily identified because it usually does *not* have removable filler caps or covers.
15. Which of the following is *not* a conventional battery rating?
   (A) Hot cranking amps.
   (B) Reserve capacity rating.
   (C) Watt rating.
   (D) Cold cranking amps.

ASE-Type Questions

1. An automotive battery produces:
   (A) hydrogen gas.
   (B) voltage.
   (C) direct current.
   (D) All of the above.

2. Battery charging converts:
   (A) *atoms into electrolytes.*
   (B) *electrical energy into chemical energy.*
   (C) *chemical energy into electrical energy.*
   (D) *lead oxide into sulfuric acid and water.*
3. Which of the following is *not* a battery cell component?
   (A) *Eye.*
   (B) *Battery acid.*
   (C) *Positive plate.*
   (D) *Negative plate.*
4. Battery plates are grids that are coated with:
   (A) *plastic.*
   (B) *copper.*
   (C) *thin steel.*
   (D) *porous lead.*
5. Which of the following connect a battery's plates?
   (A) *Posts.*
   (B) *Straps.*
   (C) *Separators.*
   (D) *Side terminals.*
6. The active material on positive plates is:
   (A) *antimony.*
   (B) *sponge lead.*
   (C) *lead peroxide.*
   (D) *None of the above.*
7. Which of the following serve as spark arrestors?
   (A) *Battery caps.*
   (B) *Battery plates.*
   (C) *Battery separators.*
   (D) *All of the above.*
8. Which of the following shows the general charge condition of a battery?
   (A) *Indicator eye.*
   (B) *Test indicator.*
   (C) *Charge indicator.*
   (D) *All of the above.*
9. When testing a battery's charge condition, the indicator shows a visible dark green dot. Technician A interprets this as meaning the battery needs to be charged. Technician B feels the dot indicates the battery is fully charged. Who is right?
   (A) *A only.*
   (B) *B only.*
   (C) *Both A and B.*
   (D) *Neither A nor B.*
10. Each of the following provides a means of connecting battery plates to a car's electrical system *except:*
    (A) *battery caps.*
    (B) *battery posts.*
    (C) *side terminals.*
    (D) *battery terminals.*

Activities—Chapter 29

1. Survey the service managers of at least three businesses that sell and install vehicle batteries. Find out how they dispose of batteries they remove from vehicles.
2. Find the best battery value. Gather information from catalogs or advertisements, or visit stores that sell automotive batteries. Find the cold cranking ratings and prices of comparable-size batteries from different stores, and make a chart of your findings. Which will give you the most for your money?
3. Construct a model of a vehicle battery element (cell) for classroom display. Clearly label all components.

30

Battery Testing and Service

After studying this chapter, you will be able to:

- Visually inspect a battery for obvious problems.
- Perform common battery tests.
- Clean a battery case and terminals.
- Charge a battery.
- Jump start a car using a second battery.
- Replace a defective battery.
- Describe safety practices to follow when testing and servicing batteries.
- Correctly answer ASE certification test questions on battery service.

A "***dead battery***" (discharged battery) is a very common problem. The engine will usually fail to crank and start. Even though the lights and horn may work, there is not enough "juice" (current) in the battery to operate the starting motor.

Since a dead battery is a frequent complaint, it is important for you to know how to inspect, test, and service vehicle batteries. This chapter covers the most common tasks relating to battery service. Study it carefully and you will be prepared for later chapters on starting and charging systems.

Battery Maintenance

If a battery is not maintained properly, its service life will be reduced. Battery maintenance should be done periodically—during tune-ups, grease jobs, or anytime symptoms indicate battery problems. ***Battery maintenance*** typically includes:

- Checking the electrolyte level or the indicator eye.
- Cleaning battery terminal connections.
- Cleaning the battery top.
- Checking the battery hold-down and tray.
- Inspecting for physical damage to the case and terminals.

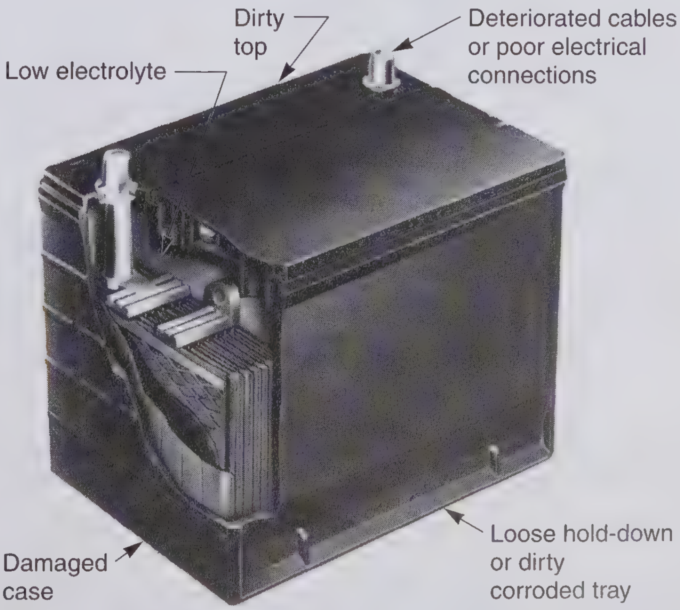
Inspecting Battery Condition

Inspect the battery anytime the hood is opened. Check for the types of problems shown in **Figure 30-1.** Look for a dirt buildup on the battery top. Look for case damage, loose or corroded connections, or any other trouble that could upset battery operation. If a problem is found, correct it before it gets worse.

Warning!
Wear eye protection when working around batteries. Batteries contain sulfuric acid, which can cause blindness. Even the film buildup on a battery can contain acid.

Battery Leakage Test

A ***battery leakage test*** will find out if current is discharging across the top of the battery case. A dirty battery



Dirty top
Deteriorated cables or poor electrical connections
Low electrolyte
Loose hold-down or dirty corroded tray
Damaged case

Figure 30-1. Visually inspect batteries for these kinds of problems. If any problems are found, correct them. (GMC)

can run down (discharge) when not in use. This can shorten battery life and cause starting problems.

To do a battery leakage test, set a voltmeter on a low setting. Touch the acid-resistant probes on the battery as shown in **Figure 30-2.** If the meter registers voltage, current is leaking out of the battery cells. You need to clean the battery top.

Cleaning the Battery Case

If the top of the battery is dirty, wash it with baking soda and water. This will neutralize and remove the acid-dirt mixture. If not a maintenance-free battery, be careful not to let debris enter the filler openings. See **Figure 30-3.**

Battery Terminal Test

A ***battery terminal test*** quickly checks for a poor electrical connection between the battery cables and terminals. A voltmeter is used to measure voltage drop across the cables and terminals, as in **Figure 30-4.**

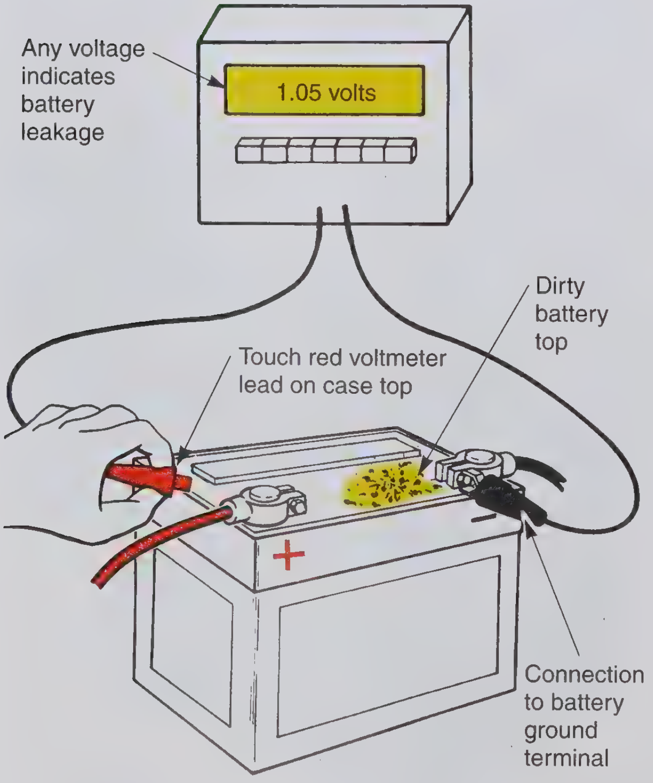
To perform a battery terminal test:

1. Connect the negative voltmeter lead to the cable end.
2. Touch the positive voltmeter lead on the battery terminal.
3. Disable the ignition or injection system so the engine will not start.
4. Crank the engine while watching the voltmeter reading.

If the voltmeter shows over 0.5 volt, there is a high resistance at the cable connection. This would tell you to clean the battery connections. A clean, good electrical connection would have less than a 0.5 volt drop.

Cleaning Battery Terminals

To clean the terminals, remove the battery cables. See **Figure 30-5.** Use a six-point wrench if the bolt or nut is extremely tight. Use pliers only on a spring-type cable



Any voltage indicates battery leakage
1.05 volts
Touch red voltmeter lead on case top
Dirty battery top

end or when the fastener head is badly corroded and rounded off. Be careful not to damage the post or side terminal with excess side force.

To clean post-type terminals, use a cleaning tool like the one in **Figure 30-6.** Use the female end to clean the post. Use the male end on the terminal. Twist the tool to remove the oxidized outer surface on the connections. To clean side terminals, use a small wire brush. Polish both the cable end and the mating surface on the battery terminal.

Caution!
Do not use a knife or scraper to clean battery terminals. This removes too much metal and can ruin the terminal connection.

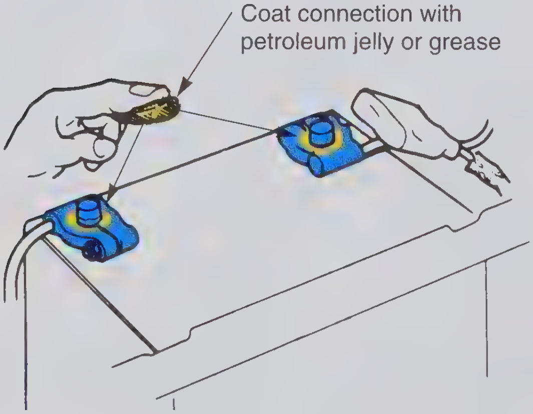
When reinstalling the cables, coat the terminals with petroleum jelly or white grease, **Figure 30-7.** This will keep acid fumes off the connections and prevent them from corroding again. Tighten the fasteners just enough to secure the connection. Overtightening can strip the cable bolt threads.

Tech Tip!
When disconnecting the car battery, consider using a memory saver to provide power to the computer. This will keep all driver programmed information intact (clock, radio stations, etc.). It will also prevent the computer from having to relearn information, which could temporarily upset driveability. Some systems require over a hundred miles of driving to relearn everything (ideal ignition timing, injector pulse width, etc.) and operate normally.

Checking Battery Electrolyte Level

Unlike older batteries, maintenance-free batteries do not need periodic electrolyte service under normal conditions. Maintenance-free batteries are designed to operate for long periods without loss of electrolyte. Older batteries with removable vent caps, however, must have their electrolyte level checked.

Warning!
The invisible hydrogen gas produced by the chemical reaction in a battery is flammable. Keep all sparks and flames away from the top of a battery. Batteries can explode if the gas is ignited!



Coat connection with petroleum jelly or grease

Figure 30-7. Before reconnecting battery cables, coat the connection with petroleum jelly or white grease. This will help prevent corrosion from battery gases. Do not overtighten cable fasteners or damage may result. Most terminals are made of very soft lead. (Honda)

Many older batteries must have their vent caps removed when checking the electrolyte. The electrolyte should just cover the top of the battery plates and separators. Most batteries have a fill ring (electrolyte level indicator) inside the filler cap opening. The electrolyte should be even with the fill ring.

If the electrolyte is low, fill the cells to the correct level with ***distilled water*** (purified water). Distilled water should be used because it does not contain many of the impurities found in tap water. Water taken directly out of a water faucet can contain chemicals that reduce battery life. The chemicals can contaminate the electrolyte and collect in the bottom of the battery case. If enough contaminants collect in the battery, the cell plates can short out, ruining the battery.

Battery Overcharging

If water must be added at frequent intervals, the charging system may be overcharging the battery. A faulty charging system can force excessive current into the battery. Battery gassing can then remove water from the battery.

Note!
Refer to Chapter 34, *Charging System Diagnosis, Testing, and Repair,* for more information on this subject.

Checking Battery Charge

When measuring battery charge, you are checking the condition of the battery electrolyte and battery plates. For example, if lights are left on without the engine running, the battery will run down (discharge). Current flow out of the battery will steadily reduce available battery power. There are several ways to measure battery charge.

Some batteries use a charge indicator eye that shows battery charge. You simply look at the eye in the battery cover to determine battery charge, **Figure 30-8.** This was covered in the previous chapter.

Hydrometer Check

A ***hydrometer*** measures the specific gravity (weight or density) of a liquid. A battery hydrometer measures the specific gravity (and the state of the charge) for battery electrolyte. Look at **Figure 30-9.**

Water has a specific gravity standard of one (1.0). Fully charged electrolyte has a specific gravity of between 1.265 and 1.299. The larger number denotes that electrolyte is more dense (heavier) than water.

As a battery becomes discharged, its electrolyte has a larger percentage of water. Thus, a discharged battery's electrolyte will have a lower specific gravity than a fully

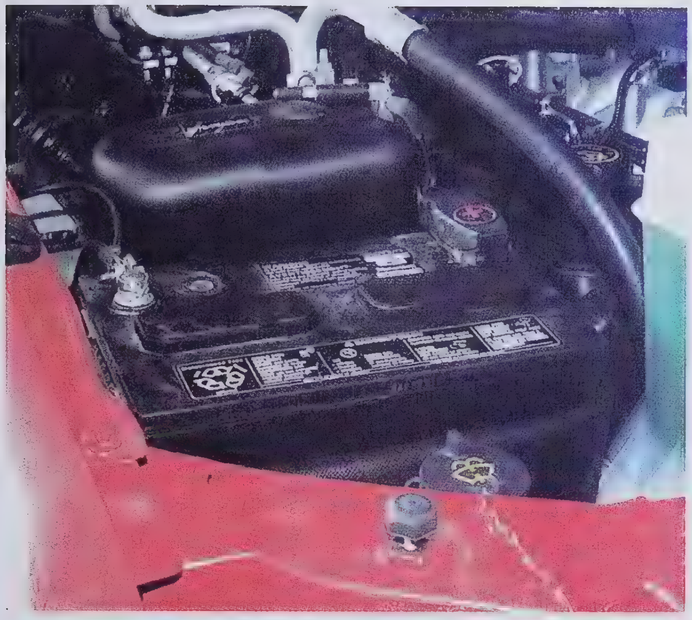


Figure 30-8. The battery is vital to starting a vehicle. Always inspect the battery and its cables during service. They can be located in the engine compartment, under the back seat, or in the trunk. (GMC)

charged battery. This rise and drop in specific gravity can be used to check the charge in a battery.

To use a float-type hydrometer, squeeze the hydrometer bulb. Immerse the end of the hydrometer in the electrolyte. Then release the bulb, **Figure 30-9.** Compare the numbers on the hydrometer float with the top of the electrolyte. Hold the hydrometer even with your line of sight. Wear safety glasses and do not drip electrolyte on anything. See **Figure 30-10.**

Most float-type hydrometers are not temperature correcting. However, some models have a built-in thermometer and a conversion chart. This will let you compensate for battery temperature.

To use a ball-type hydrometer, draw electrolyte into the hydrometer with the rubber bulb. Then note the number of balls floating in the electrolyte. Instructions on the hydrometer will tell you whether the battery is fully charged or discharged.

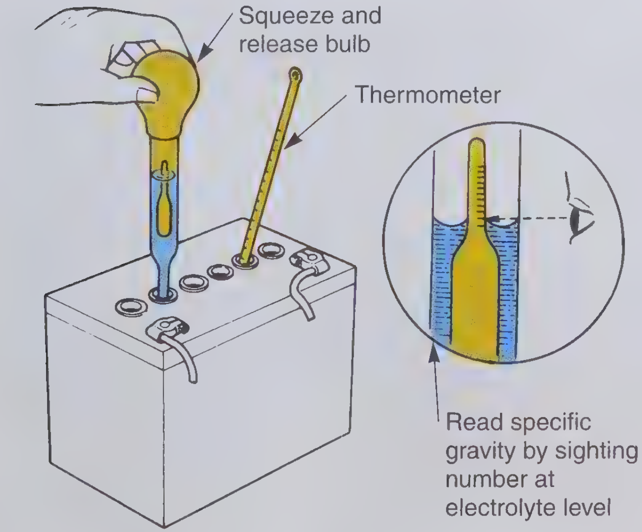
A needle-type hydrometer uses the same principle as the ball-type. When the electrolyte is drawn into the hydrometer, it causes a plastic needle to register specific gravity.

Hydrometer Readings

A fully charged battery should have a hydrometer reading of at least 1.265. If the reading is below 1.265, the battery needs recharging or it may be defective.

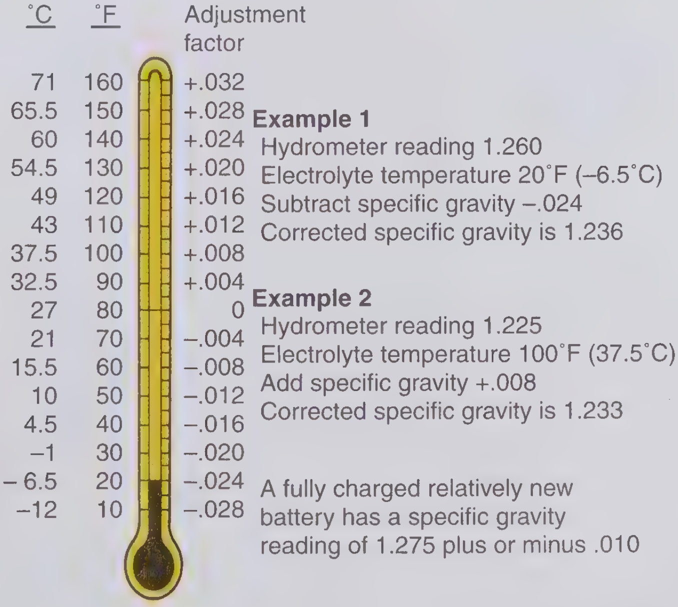
A discharged battery could have several causes:

- Defective battery.
- Charging system problem (loose alternator belt, for example).
- Starting system problem.
- Poor cable connections.
- Engine performance problem requiring excessive cranking time.



Squeeze and release bulb
Thermometer
Read specific gravity by sighting number at electrolyte level

Figure 30-9. To check battery charge, draw electrolyte into a hydrometer by squeezing and releasing the bulb. Read specific gravity on the float at the top level of electrolyte. The temperature of the electrolyte will affect the reading. (Mazda)



Example 1
Hydrometer reading 1.260
Electrolyte temperature 20˚F (–6.5˚C)
Subtract specific gravity –.024
Corrected specific gravity is 1.236

Example 2
Hydrometer reading 1.225
Electrolyte temperature 100˚F (37.5˚C)
Add specific gravity +.008
Corrected specific gravity is 1.233

A fully charged relatively new battery has a specific gravity reading of 1.275 plus or minus .010

Figure 30-10. Study examples of using a hydrometer correction chart. (DaimlerChrysler)

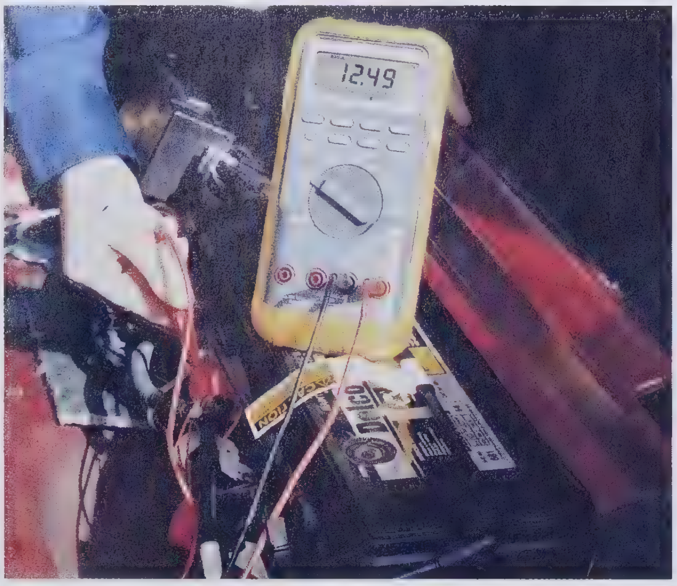


Figure 30-11. A digital voltmeter will check the general charge of a battery. Turn on headlights or blower for a light load, then read the meter. Generally, voltage below 12.5 V indicates the amount of battery discharge. This battery shows 12.49 V, which is about 100% of a full charge with a 5 amp load. (Fluke)

- Electrical problem drawing current out of battery with ignition key off.

A defective battery can be found with a hydrometer by checking the electrolyte in every cell. If the specific gravity in any cell varies excessively from other cells (25–50 points), the battery is usually ruined. Cells with low readings may be shorted. When all the cells have an equal specific gravity, the battery can usually be restored by recharging.

With maintenance-free batteries, the hydrometer is not commonly used. A voltmeter and ammeter or a load tester (covered later in the chapter) can be used to quickly determine battery condition.

Battery Voltage Test

A ***battery voltage test*** is done by measuring total battery voltage with a voltmeter or special tester. It will determine the general state of charge and battery condition quickly. A battery voltage test is used on maintenance-free batteries. These batteries do not have filler caps that can be easily removed for testing with a hydrometer.

Look at **Figure 30-11.** Connect the meter across the battery terminals. Turn on the car's headlights or heater blower to provide a light load. Read the meter.

A fully charged battery under a 5 amp load should have 12.5 volts. The lower the voltage, the less charge on the battery.

Other tests are needed to find the actual problem when a battery fails a voltage test. The chart in **Figure 30-12** compares specific gravity (hydrometer readings) and battery voltage under load. Note the relationship.

Cell Voltage Test

Just like a hydrometer cell test, a ***cell voltage test*** will let you know if the battery is defective or just discharged. To do a cell voltage test, insert the special cadmium (acid-resistant metal) tips of a low voltage reading voltmeter into each cell. Start at one end of the battery. Work your way down, testing each cell carefully. Some manufacturers recommend battery fast-charging during this test. Refer to a service manual for details.

If cell voltages are low, but equal, recharging will usually restore the battery. If cell voltage readings vary more than 0.2 volts, the battery is faulty.

Warning!
Make sure you do not drip electrolyte on the vehicle or your skin. The acid in the electrolyte will eat the paint or burn your skin.

Battery Drain Test

A ***battery drain test*** will check for an abnormal current draw with the ignition key off. When a battery goes dead without being used, you may need to check for a current drain. It is possible that there is a short or other problem constantly discharging the battery.

A battery can be discharged if an electrical accessory remains on when the ignition switch is shut off. For example, a short in a switch could cause a glove box light to always stay on. This could slowly drain the battery and cause a starting problem.

Battery Voltage

Load on battery (Amps)	Specific Gravity (Percent charge)				
	1.265 (100%)	1.250 (95%)	1.230 (75%)	1.200 (50%)	1.175 (25%)
0	12.7	12.6	12.5	12.4	12.2
5	12.5	12.4	12.3	12.1	11.8
15	12.3	12.2	12.0	11.7	11.3
25	12.1	11.9	11.6	11.2	10.7

This is the range in which most vehicle batteries normally operate in customer service.

At 1.180 and below, starting will be unreliable and function of other circuits may be erratic.

Figure 30-12. Chart shows how battery voltage relates to specific gravity (hydrometer readings). A voltage test is needed on maintenance-free batteries, which do not have removable filler caps. (DaimlerChrysler)

To perform a battery current drain test:

1. Make the ammeter connections shown in **Figure 30-13.**
2. Close the doors and trunk.
3. Unscrew the underhood lightbulb, if needed.
4. Read the ammeter and compare your reading to specifications.

Caution!
To prevent meter damage, do not operate starting motor or any high-current-draw device (blower motor) with the meter connected in series for measuring current drain. High current draw will blow the meter fuse or damage the meter.

If everything is off (good condition), the ammeter should read almost zero or only a few milliamps (10 mA, typically). However, an ammeter reading above this would point to a drain and a problem. To help pinpoint a drain, pull fuses one at a time. When the ammeter reads zero, the problem is in the circuit on that fuse.

Remember that normal parasitic current drain for the clock and computers can discharge a battery if the vehicle sits unused for an extended period. Also account for this small current draw when checking for a battery drain.

Battery Chargers

When tests show that a battery is discharged, a ***battery charger*** may be used to re-energize it. The battery charger will force current back into the battery to restore the charge on the plates and in the electrolyte. It contains a step-down transformer that changes wall outlet voltage (around 120 volts) to a voltage slightly above battery voltage (14–15 volts). **Figure 30-14** shows a battery charger.

Figure 30-13. If the battery discharges while not being used, perform a battery drain test. Connect an ammeter in series with the negative cable. If current flowing out of the battery with everything turned off exceeds specifications, an electrical problem is discharging the battery. By pulling fuses, you can isolate the problem circuit. If the drain stops flowing with the fuse pulled, that circuit is at fault. (Fluke)

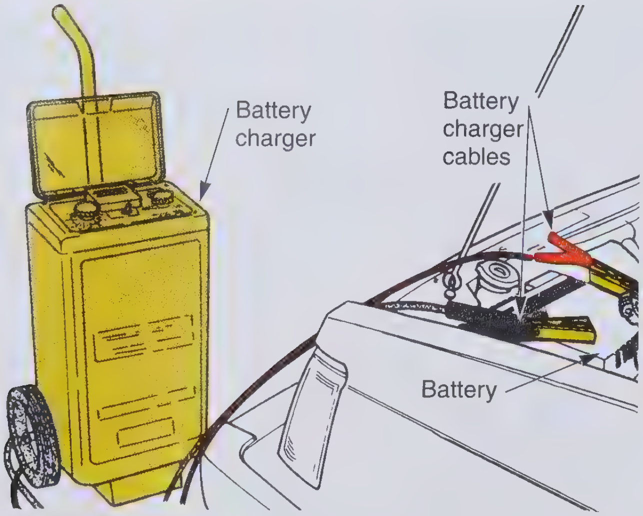

Figure 30-14. A battery charger forces current through the battery to restore the charge on the plates. (DaimlerChrysler)

There are two basic types of battery chargers: the slow charger and the fast charger. Sometimes both are incorporated into one unit.

Slow Charger

A ***slow charger,*** also called a ***trickle charger,*** feeds a small amount of current into the battery. When using a slow charger, charging time is relatively long (about 12 hours at 10 amps), but the chemical action inside the battery is improved. During slow charging, the active materials are plated back on the battery plates better than they are during fast charging. When time allows, use a slow charger. Look at **Figure 30-15.**

Fast (Quick) Charger

A ***fast charger,*** also called a ***quick*** or ***boost charger,*** forces a high current flow into the battery for rapid recharging. A fast charger is shown in **Figure 30-16.** It is commonly used in auto shops. When the customer needs the car, time may not allow the use of a slow charger.

Fast charging will usually allow engine starting in a matter of minutes. If possible, slow charging is recommended after fast charging.

Warning!
Before connecting a battery charger to a battery, make sure the charger is turned off. Also, check that the work area is well ventilated. If a spark ignites any battery gas, the battery could explode. Wear eye protection!

Charging a Battery

To use a battery charger, connect the *red* charger lead to the positive terminal of the battery. Connect the *black* charger lead to the negative terminal of the battery. With side terminal batteries, use adapters like those shown in **Figure 30-17.**

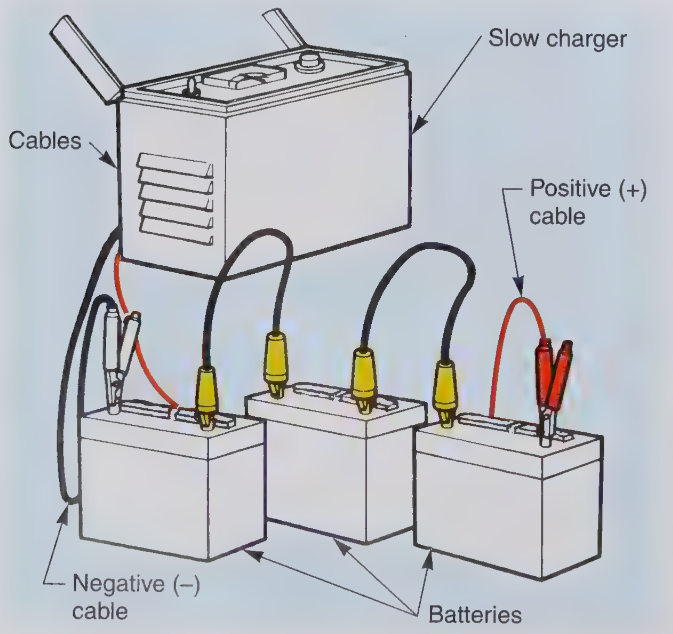

Figure 30-15. A slow charger forces only a small amount of current through the battery. Since slow charging requires several hours, several batteries may be connected to get more done.

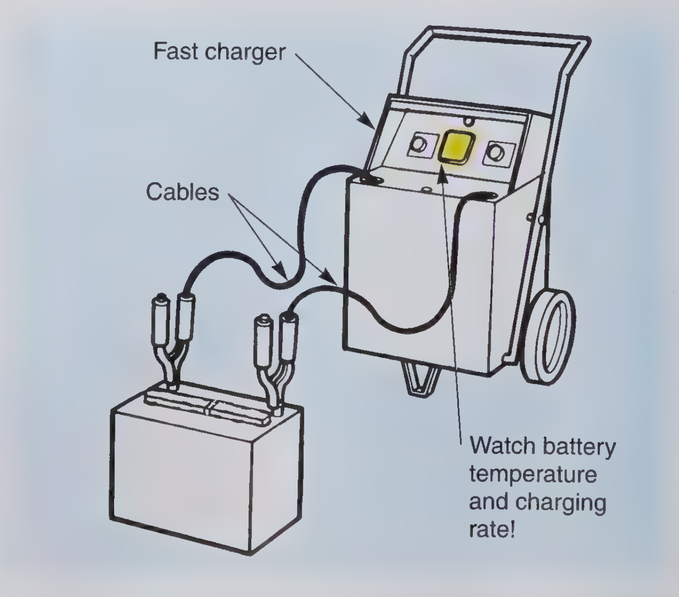

Figure 30-16. Fast charging is done in emergency situations. Slow charging should follow fast charging to restore the battery properly. Do not let battery temperature go above about 125°F (52°C) or battery damage may occur.

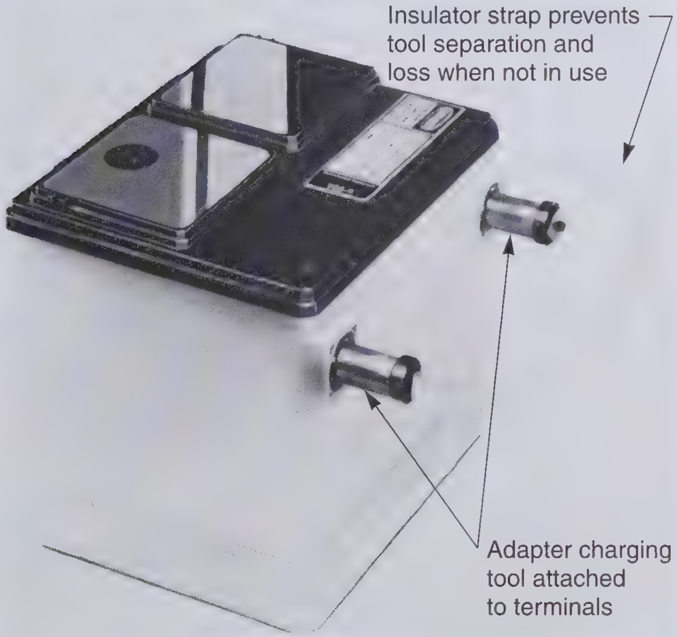
Caution!
Make sure you do not reverse the charger connections on the vehicle's charging system or electronics could be damaged. Set the charger controls and turn on the power.

When fast charging, do not exceed a charge rate of 35 amps. Also, battery temperature must not exceed 125°F (52°C). Exceeding either charge rate or temperature could damage the battery.

If you suspect a battery is frozen or has ice in it from extremely cold weather, do not charge it. Charging a frozen battery can rupture the case and cause an explosion. Allow the battery to thaw in the warm shop before charging.

Jump Starting

In emergency situations, it may be necessary to ***jump start*** a vehicle by connecting another battery to the discharged battery. Look at **Figure 30-18.** The two batteries are connected *positive to positive* and *negative to negative*. Connect the red jumper cable to the positive terminal of both batteries. Then, connect one end of the black jumper cable to the negative terminal of the good battery. Finally, connect the other end of the black jumper cable to a good ground on the vehicle with the bad battery. See **Figure 30-19.**



Insulator strap prevents tool separation and loss when not in use

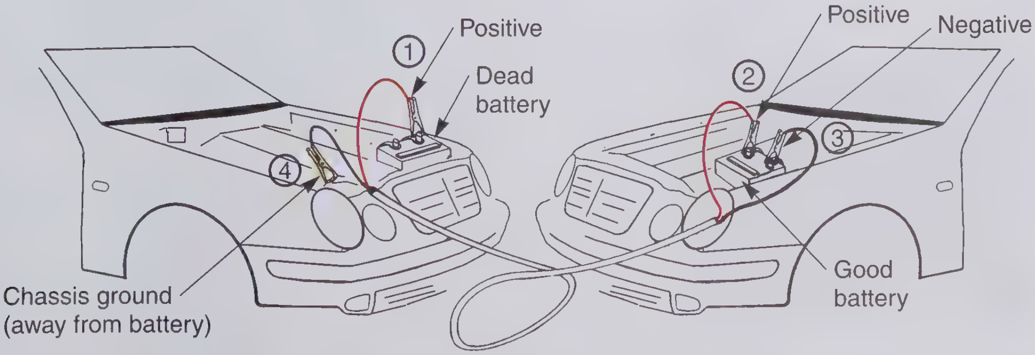
Figure 30-19. Close-up of jumper connections shows the connection of the negative (black) jumper to chassis ground. A spark near the dead battery could make battery gases explode. (DaimlerChrysler)



①
Positive
Dead battery
④
Chassis ground (away from battery)
Positive
Negative
②
③
Good battery

Figure 30-18. Jumper cables can be used to start a vehicle with a dead battery. 1—Connect one end of the red jumper cable to the positive terminal of the dead battery. 2—Connect the other end of the red jumper to the positive terminal of the good battery. 3—Connect one end of the black jumper cable to the negative terminal of the good battery. 4—Connect the other end of the black jumper to a good ground on the disabled vehicle, away from the dead battery. This will keep sparks away from battery gases. Run the engine in the car with the good battery while starting the vehicle with the dead battery. (Belden)

Warning!
Do not short jumper cables together or connect them backwards. This could cause serious damage to the charging or computer systems. By connecting the last negative jumper cable to a ground away from the battery, any spark will be further away from the explosive battery gas.

Battery Load Test

A battery load test, also termed a battery capacity test, is one of the *best* methods of checking battery condition. It tests the battery under full current load.

The hydrometer and voltage tests were general indicators of battery condition. The battery load test, however, actually measures the current output and performance of the battery. It is one of the most common and informative battery tests used in automotive garages. Refer to **Figure 30-20.**

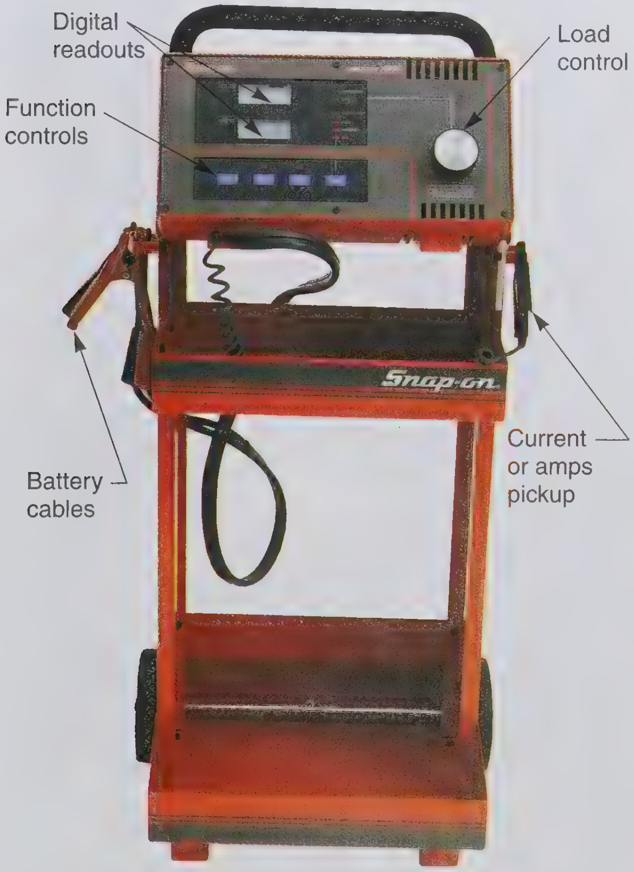


Figure 30-20. A battery load tester is the most accurate method of determining battery condition. It is a commonly used testing device that measures actual battery performance. (Snap-On Tools)

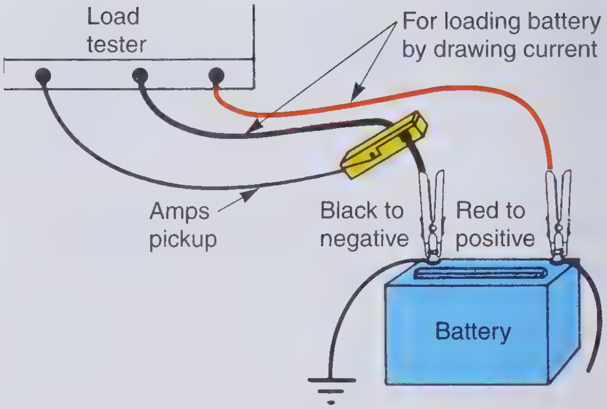

Figure 30-21. Load testers are connected as shown. Clamp the large cables to the battery. Clip the inductive amps pickup around the negative tester cable. Large cables load the battery by drawing current through the tester. Inductive pickup operates the ammeter in the tester. (Marquette)

Connecting a Load Tester

Connect the load tester to the battery terminals. If the tester is an inductive type (clip-on ammeter lead senses field around outside of cables), use the connections shown in **Figure 30-21.** If the tester is *not* inductive, you must connect the ammeter in series.

Control settings and exact procedures vary. Follow the directions provided with the testing equipment.

Double-Check Battery Charge

Before load testing, make sure the battery is adequately charged. Use a hydrometer or digital voltmeter as discussed earlier. The load tester can be used to check the battery charge. Adjust the load control to draw 50 amps for 10 seconds. This will remove any surface charge. Then, check no-load battery voltage (also called open circuit voltage, or OCV), by reading the voltmeter.

A ***fully charged battery*** should have an OCV (no-load, open circuit voltage) of 12.4 volts or higher. If battery voltage is below 12.4 volts, charge the battery before load testing. The battery is probably bad if it fails a second test after charging.

Determine Battery Load

Before load testing a battery, you must calculate how much current draw should be applied to the battery.

If the amp-hour rating is given, load the battery to three times its amp-hour rating. For example, if the battery is rated at 60 amp-hours, test the battery at 180 amps (60 × 3 = 180).

Battery ratings			
Cold cranking current	Amp-hour (approx.)	Watts	Load test amps
200	35–40	1800	100 amps
250	41–48	2100	125 amps
300	49–62	2500	150 amps
350	63–70	2900	175 amps
400	71–76	3250	200 amps
450	77–86	3600	225 amps
500	87–92	3900	250 amps
550	93–110	4200	275 amps

Figure 30-22. This chart shows different battery ratings and calculated current values for load testing. (Marquette)

Many batteries are now rated in SAE cold cranking amps, rather than amp-hours. To determine the load test for these batteries, divide the cold crank rating by two. For instance, a battery with a 400-cold cranking amps rating should be loaded to 200 amps (400 ÷ 2 = 200). The watt is another battery performance rating.

Figure 30-22 is a chart that compares battery ratings. A ***load conversion chart*** will normally be provided with the load testing equipment. Refer to this material when in doubt.

Loading the Battery

After checking the battery charge and finding the amp load value, you are ready to test the battery output. Double-check that the tester is connected properly. Then, turn the load control knob until the ammeter reads the correct load for your battery, **Figure 30-22.** Hold the load for 15 seconds. Next, read the voltmeter while the load is applied. Then, turn the load control completely off so the battery will not be discharged.

Load Test Results

If the voltmeter reads 9.5 volts or more at room temperature, the battery is good. Six-volt batteries should maintain 4.8 volts. These voltages are based on a battery temperature above 70°F (21°C).

A cold battery may show a lower voltage. You will need a temperature compensation chart, like the one in **Figure 30-23.** It allows for any reduced battery performance caused by a low temperature.

If the voltmeter reads below 9.5 volts at room temperature, battery performance is poor. This would show that the battery is not producing enough current to properly run the starting motor. Before replacing the battery, however, a quick charge test should be completed.

Approximate electrolyte temperature	Minimum acceptable voltage under load for good battery
60°F (16°C)	9.5
50°F (10°C)	9.4
40°F (4°C)	9.3
30°F (–1°C)	9.1
20°F (–7°C)	8.9
10°F (–12°C)	8.7
0°F (–18°C)	8.5

Figure 30-23. To load test a battery, turn the load control knob until the ammeter reads calculated test current. Hold the load or current for 15 seconds and read the voltmeter. If the reading is below voltages in the chart for the specific temperature, the battery is probably bad. (Snap-On Tools)

Quick (3 Minute) Charge Test

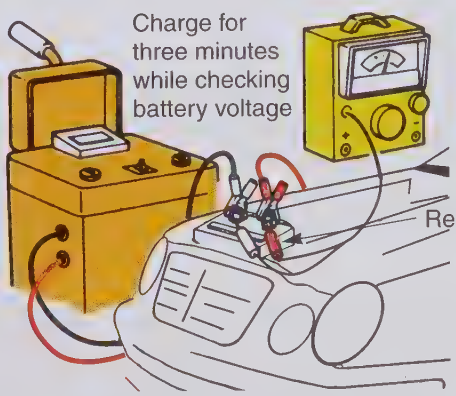
A ***quick charge test,*** also called a ***3 minute charge test,*** will determine if the battery is ***sulfated*** and the plates ruined. If the battery load test results are poor, fast charge the battery. Charge for three minutes at 30–40 amps. Test the voltage while charging, as shown in **Figure 30-24.**

If the voltage goes above 15.5 volts (12-volt battery) or 7.8 volts (6-volt battery), the battery plates are sulfated and ruined. A new battery should be installed in the vehicle.

Other Battery-Related Problems

If the battery passes all its tests but does not perform properly (starting motor does not crank, for example), the following are some likely problems to check out.

- Defective charging system.
- Battery drain (light or other accessory on).



Charge for three minutes while checking battery voltage
Red

Figure 30-24. The 3 minute charge test will double-check the load test. Charge the battery at 30–40 amps while measuring the battery voltage for three minutes. If voltage increases above 15.5 volts, replace the battery.

- Loose alternator belt.
- Corroded, loose, or defective battery cables.
- Defective starting system.

Note!
Later textbook chapters cover the starting and charging systems. They will give you more information relating to battery service.

Activating Dry-Charged Battery

A new dry-charged battery must be activated (readied for service) before installation. Put on safety glasses and rubber gloves. Remove the cell caps or covers. Using a plastic funnel (not a metal funnel) pour electrolyte into each cell. Pour in enough electrolyte to just cover the plates and separators.

Replace the caps. Charge the battery as recommended by the manufacturer. After charging, recheck the electrolyte level. Install the battery.

Removing and Replacing a Battery

To remove a battery, first disconnect the cables. Then loosen the battery hold-down. Using a ***battery strap*** or tool, **Figure 30-25,** carefully lift the battery out of the vehicle.

Warning!
Always wear safety glasses when carrying a battery. If you drop a battery, electrolyte (acid) can squirt out of the vent caps or a broken case and into your face and eyes.

To install a battery, gently place the battery into its clean tray or box. Check that the battery fits properly. The tray edge must not cut through and rupture the plastic case. Tighten the hold-down and install the cables. See **Figure 30-26.**

Tech Tip!
The replacement battery should have a power rating at least *equal* to factory recommendations. If an ***undersize battery*** (lower watt rating) is installed, starting motor performance and battery service life may be reduced.

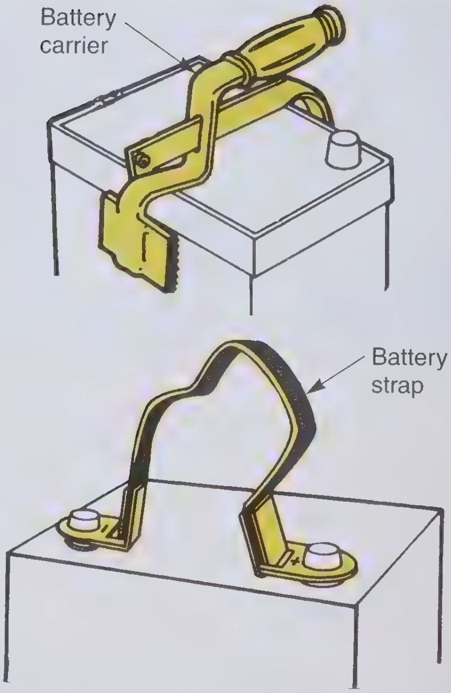


Figure 30-25. If you lose your grip and drop a battery, acid could splash out, causing eye or skin injury. Always use a battery strap or carrier and wear eye protection for safety. (Florida Dept. of Voc. Ed.)

Figure 30-26. When installing a battery, do not overtighten cable terminals or you could strip threads. Make sure the hold-down is secure. This battery is located under the rear seat in the passenger compartment.

Duff's Garage

Problem: Mr. Nagdamoor drives his 1993 Cavalier to the shop, complaining that his new battery keeps going dead and that he has to jump start the engine every morning.

Diagnosis: Mr. Nagdamoor explains to Duff that the vehicle's battery is less than three months old and that it seemed fine for several weeks. For the last few days, however, he had to jump start the vehicle after it sat overnight. The car generally starts fine after the initial jump start. Since the battery is new and the problem occurs after the vehicle sits overnight, the symptoms seem to point to a battery drain problem rather than a charging or starting system problem. Duff thinks an electrical component might be staying on after the vehicle is turned off, draining the battery.

Duff relays the information he gathered to the shop's electrical technician. The technician first turns off all the vehicle's electrical accessories and removes the lightbulb under the hood. He then connects an ammeter in series with one of the battery cables. The ammeter shows a 2-amp draw, confirming Duff's suspicion that something is draining the vehicle's battery. After pulling fuses to see which circuit is causing the current drain (ammeter stops registering when the fuse to the circuit containing the drain is removed), the technician is able to narrow the problem to the accessory lighting system. He then begins removing bulbs from the accessory lighting circuit while watching the ammeter. The technician discovers that the current draw stops when the trunk bulb is removed and the trunk is closed. Further tests show that the switch in the trunk lighting circuit is shorted closed, supplying power to the trunk light even when the trunk is closed. This is slowly draining the battery whenever the vehicle sits unused for an extended period.

Repair: After changing the trunk light switch, the technician again connects the ammeter to check for excessive current draw. Not finding any other problems, the technician charges the battery and performs a charging system output test. The charging system shows an output of 13.0 volts with all accessories turned off. Finally, the technician returns the vehicle to Mr. Nagdamoor, assuring him that the problem has been corrected.

Summary

- A "dead battery" (discharged battery) is a very common problem. The engine will usually fail to crank and start.
- A battery leakage test will find out if current is discharging across the top of the battery case.
- If the top of the battery is dirty, wash it down with baking soda and water.
- A battery terminal test quickly checks for a poor electrical connection between the battery cables and terminals.
- When reinstalling the cables, coat the terminals with petroleum jelly or white grease.
- Invisible hydrogen gas produced by the chemical reaction in a battery is very flammable. Keep all sparks and flames away from the top of a battery. Batteries can explode if the gas is ignited!
- A battery voltage test is done by measuring total battery voltage with an accurate voltmeter or a special tester.
- A battery drain test will check for an abnormal current draw with the ignition key off.
- When tests show that a battery is discharged, a battery charger may be used to re-energize it.
- In emergency situations, it may be necessary to jump start a vehicle by connecting another battery to the discharged battery.
- A fully charged battery should have an OCV (no-load, open circuit voltage) of 12.4 volts or higher.
- The replacement battery should have a power rating equal to factory recommendations. If an undersize battery is installed, starting motor performance and battery service life will be reduced.

Review Questions—Chapter 30

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What five tasks does battery maintenance typically include?
2. A(n) _____ _____ _____ will determine whether current is discharging across the top of the battery case.
3. If a voltmeter shows a 0.8 volt drop across the battery post-to-cable connection, what should be done?

4. A knife or scraper is a good too for cleaning corroded battery terminals. True or False?
5. When you measure _____ _____, you check the condition of the battery electrolyte and plates.
6. List six reasons for a discharged battery.
7. A battery _____ _____ is done by measuring total battery voltage with an accurate voltmeter. A(n) _____ _____ battery should have over 12 volts.
8. A customer complains that her battery goes dead when the car is not driven for an extended period. A new battery has been installed and tested by another shop. Technician A says that starting motor current draw should be measured. A shorted starting motor could be draining the battery. Technician B says that a battery drain test should be done. An electrical short could be discharging the battery, even with the ignition key off. Who is correct?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
9. When using a battery charger, connect the red lead to positive and the black lead to negative. True or False?
10. When fast charging a battery, you should never exceed a charge rate of _____.
11. How do you connect jumper cables safely?
12. A(n) _____ _____ _____, also termed a(n) _____ _____ _____, is one of the best methods of checking battery condition.
13. What is an inductive-type ammeter lead?
14. Explain how to do a battery load test.
15. If a 12-volt battery shows less than _____ volts during a load test at 70°F (21°C), the battery is bad.
    (A) 9.9 volts.
    (B) 9.5 volts.
    (C) 9.7 volts.
    (D) 10.0 volts.

ASE-Type Questions

1. Battery maintenance and inspection should be conducted:
   (A) during tune-ups.
   (B) during grease jobs.
   (C) anytime symptoms point to battery problems.
   (D) All of the above.
2. Each of the following can be performed using a voltmeter *except:*
   (A) battery plate test.
   (B) battery voltage test.
   (C) battery leakage test.
   (D) battery terminal test.
3. Which of the following combinations will neutralize and remove an acid-dirt mixture from a battery case?
   (A) Sulfur and water.
   (B) Baking soda and water.
   (C) White grease and a solvent.
   (D) Distilled water and gasoline.
4. Fully charged electrolyte has a specific gravity of between:
   (A) 0.724 and 0.999.
   (B) 1.000 and 2.000.
   (C) 1.265 and 1.299.
   (D) 2.435 and 2.922.
5. Which of the following is *not* a type of hand-held battery hydrometer?
   (A) Ball.
   (B) Nose.
   (C) Float.
   (D) Needle.
6. A discharged battery can be caused by a(n):
   (A) defective battery.
   (B) starting system problem.
   (C) engine performance problem.
   (D) All of the above.
7. Each of the following can be used to quickly determine battery condition on a maintenance-free battery *except:*
   (A) ammeter.
   (B) voltmeter.
   (C) load tester.
   (D) hydrometer.

8. Charging time for this device is about 12 hours.
   (A) *Fast charger.*
   (B) *Slow charger.*
   (C) *Quick charger.*
   (D) *Boost charger.*
9. Technician A feels the best test to determine battery current output and performance is the battery load test. Technician B feels hydrometer testing is the best choice. Who is right?
   (A) *A only.*
   (B) *B only.*
   (C) *Both A and B.*
   (D) *Neither A nor B.*
10. A fully charged battery should have an OCV of:
   (A) *5.5 volts.*
   (B) *12.4 volts or higher.*
   (C) *25.0 volts or higher.*
   (D) *None of the above.*

Activities—Chapter 30

1. Get permission from several classmates to conduct a battery maintenance inspection on their vehicles. Check for the points listed on page 493. Make and complete a simple checklist, or write a short report, for each vehicle inspected. Give the form or report to the vehicle owner.
2. Demonstrate to the class the proper way to make a hydrometer reading of a battery that has removable cell caps. Observe all safety precautions and note them for the class during your demonstration.
3. Show the effects of splashed electrolyte on clothing. Obtain small pieces of different clothing fabrics, attach them to a thick sheet of cardboard, and label them. Wearing gloves and eye protection, carefully apply two drops of electrolyte from a battery to each sample. Ask class members to note the effect of the electrolyte on each fabric.

Battery Diagnosis		
Procedure	**Possible results**	**Correction**
Clean the battery and check for damage to the battery case, posts, etc.	1. Loose battery post, cracked case, leaks, or any other physical damage. 2. Battery OK.	1. Replace battery. 2. Check *state of charge.*
Determine state of charge by checking the color of the battery charge indicator.	1. Green. 2. Black. 3. Clear.	1. Battery is charged. Perform *battery voltage test.* 2. Charge battery. 3. Replace battery.
Perform battery voltage test.	1. Battery voltage is above 12.40 volts. 2. Battery voltage is below 12.40 volts.	1. Perform a *load test.* 2. Charge battery.
Charge battery.	1. Battery accepted charge. 2. Battery will not accept charge.	1. Ensure that the indicator eye is green and perform *battery voltage test.* 2. Replace battery.
Perform load test.	1. Acceptable minimum voltage. 2. Unacceptable minimum voltage.	1. Battery is OK. Perform *battery drain test.* 2. Replace battery and perform *battery drain test.*
Perform battery drain test.	1. Battery drain is within specifications. 2. Battery drain exceeds specifications.	1. Vehicle is normal. 2. Eliminate excess draw.

31

Starting System Fundamentals

After studying this chapter, you will be able to:

- Explain the principles of an electric motor.
- Describe the construction and operation of a starting motor.
- Sketch a simple starting system circuit.
- Explain the operation of solenoids.
- List the functions of the main starter drive parts.
- Describe starter drive operation.
- Compare different types of starting motors.
- Describe starting system safety features.
- Correctly answer ASE Certification test questions that require a knowledge of starting system fundamentals.

The starting system has helped make the modern automobile a reliable and convenient means of transportation. It provides an easy method of starting the engine. Early "Model Ts" had to be cranked by hand to get the engine running. This took considerable strength, courage, and patience.

Few car owners would be physically capable of starting a modern, multi-cylinder engine using a hand crank. The electric starting motor is designed to crank the engine with the simple turn of a key.

Note!
If any of the principles in this chapter are unclear, use the index to locate earlier text material or refer to Chapter 8, *Basic Electricity and Electronics.*

Starting System Principles

The ***starting system*** uses battery power and an electric motor to turn the engine crankshaft for engine starting. **Figure 31-1** shows the basic parts and action of a starting system. The main parts of a starting system include:

- ***Battery***—source of energy for the starting system.

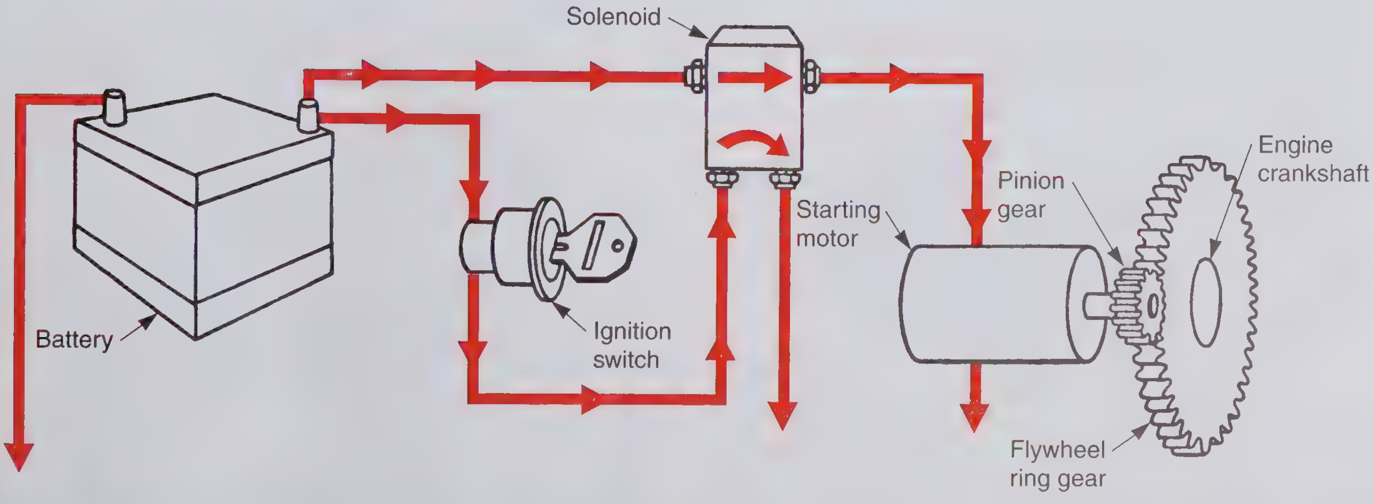

Figure 31-1. Basic starting system operation. The ignition switch energizes the solenoid. The solenoid then energizes the starting motor. The motor turns the flywheel gear for engine starting. (GMC)

- ***Ignition switch***—allows the driver to control starting system operation.
- ***Solenoid***—high-current relay (switch) for connecting the battery to the starting motor.
- ***Starting motor***—high-torque electric motor for turning the gear on the engine flywheel.

Starting System Action

When you turn the ignition key to start an engine, current flows through the solenoid coil. This closes the solenoid contacts, connecting battery current directly to the starting motor, or starter. When the starting motor circuit is electrically energized, the starter pinion gear is pushed into and meshes with the flywheel ring gear. The motor-driven pinion gear turns the flywheel ring gear until the engine starts and runs on its own power.

When the engine starts, you release the ignition key. This breaks the current flow to the solenoid and starter. The starter stops turning, and the starter gear moves away from the flywheel gear.

Tech Tip!

Some late-model starting systems are programmed to open the circuit between the ignition key and the starting solenoid when the engine is running. This prevents the driver from accidentally engaging the starting motor and grinding its pinion gear into the flywheel gear when the engine is running.

Starting Motor Fundamentals

The ***starting motor*** converts electrical energy from the battery into mechanical energy to crank the engine. It is similar to other electric motors. All electric motors (wiper motors, fan motors, fuel pump motors, etc.) produce a turning force through the interaction of magnetic fields inside the motor assembly.

Magnetic Field Action

As explained in earlier text chapters, a ***magnetic field*** is made up of invisible magnetic lines of force. The lines of force flow between the poles of a permanent magnet. They also flow around the outside of a wire that is carrying current.

Since ***like charges*** (fields) *repel* each other and ***unlike charges*** *attract each other,* magnetic fields can be used to produce motion. Look at **Figure 31-2.** Note how the lines of force in the magnet and the lines of force around the conductor act upon each other. This principle is used in electric motors.

Fields around wire and in magnet act on each other

Figure 31-2. Magnetic fields from magnets and the fields around a current-carrying conductor can be used to produce motion. Note how the fields interact. (GMC)

Simple Electric Motor

To build a simple electric motor, you would start by bending a piece of wire into a loop. When current is

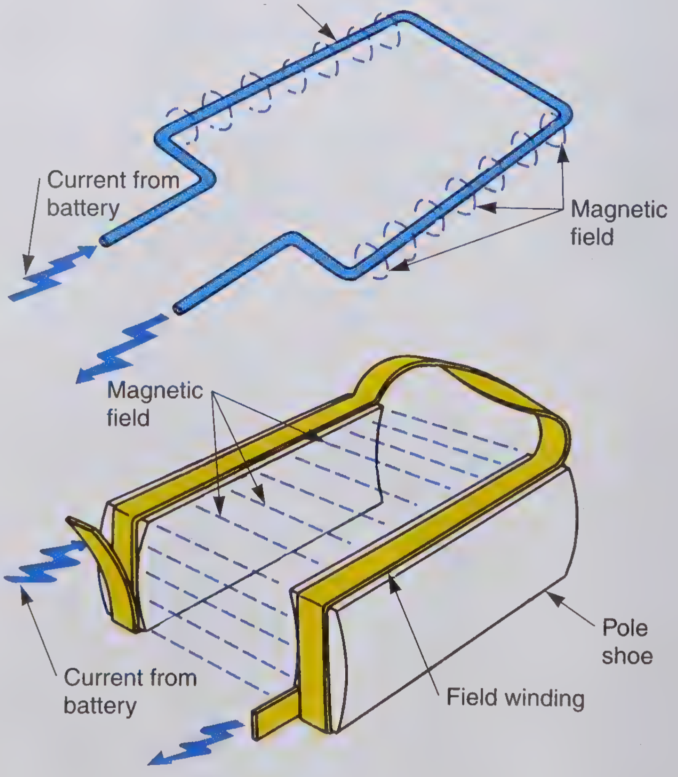

Figure 31-3. A simple electric motor. Wire bent into a loop forms the winding. When battery current flows through the winding, a field develops around the wire. Wires wrapped around pole shoes form a strong magnetic field. (Deere & Co.)

passed through the wire loop (winding), a magnetic field forms around the wire. Refer to **Figure 31-3.**

A ***magnet*** or ***pole piece*** is needed to make the loop of wire move. A magnetic field is set up between the pole pieces, also called ***pole shoes.*** See **Figure 31-3.**

Changing Electricity into Motion

Electric current can be changed into a strong rotating motion by placing the winding inside the pole shoes. When current passes through the winding, the magnetic field around the wire and the field between the pole shoes act upon each other. The winding is moved toward a vertical position, **Figure 31-4.**

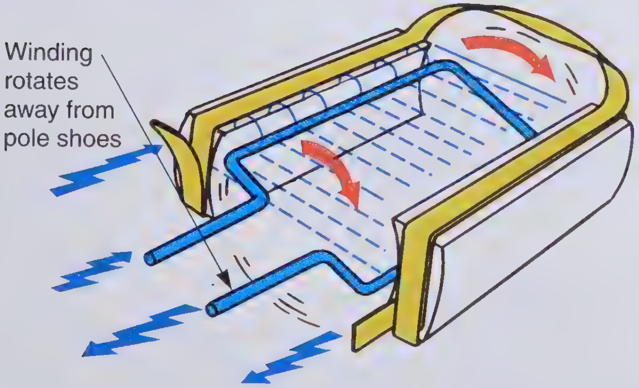

Figure 31-4. If a winding is placed inside a magnetic field, the winding rotates away from the pole shoes. (Deere & Co.)

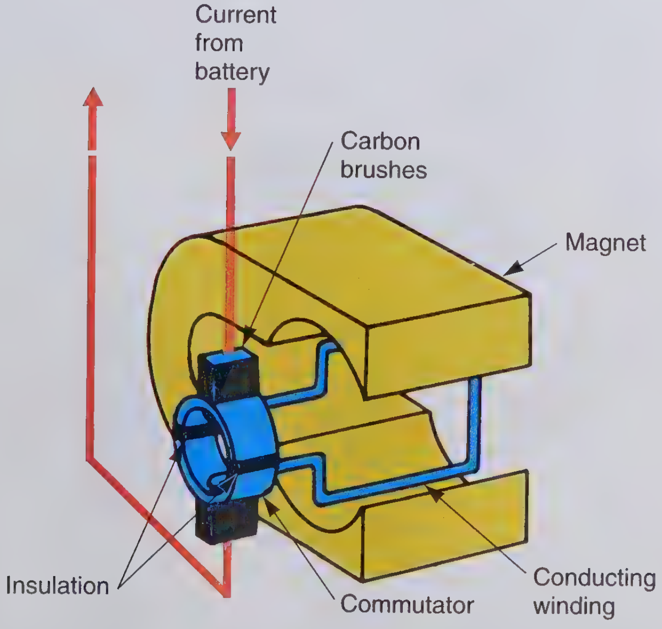

Figure 31-5. Brushes and a commutator are used to keep windings spinning. Note how the commutator reverses the electrical connection when the loop rotates around. (Robert Bosch)

Commutator and Brushes

A commutator and brushes are used to keep the electric motor spinning by controlling the current passing through the winding. Look at the simplified motor shown in **Figure 31-5.**

The ***commutator*** serves as a sliding electrical connection between the motor winding and the brushes. The commutator has segments, which are insulated from each other.

The ***motor brushes*** ride on top of the commutator. They slide on the commutator to carry battery current to the spinning winding.

Figure 31-5 illustrates commutator and brush action. As the winding rotates away from the pole shoes, the commutator segments change the electrical connection between the brushes and the winding. This reverses the magnetic field around the winding. Then the winding is again pulled around and passes the other pole shoe. The constantly changing electrical connection keeps the motor spinning. A push-pull action is set up as each loop moves around inside the pole shoe area.

Increasing Motor Power

Several windings (loops of wire) and a commutator with many segments are used to increase motor power and smoothness. Shown in **Figure 31-6,** each winding is connected to its own segment on the commutator. This provides current flow through each winding as the brushes contact each segment. As the motor spins, many windings contribute to the motion. This produces a constant and smooth turning force.

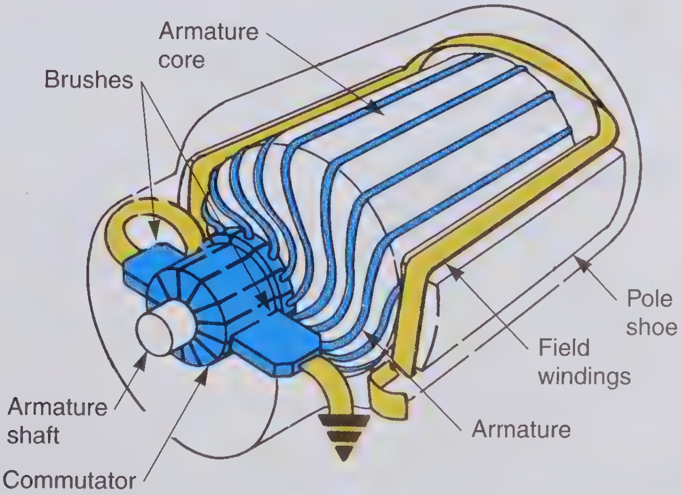

Figure 31-6. An actual starting motor has multiple commutator segments and windings to increase motor power and smoothness. (Deere & Co.)

Armature

A starting motor, unlike our simple motor, must produce very high ***torque*** (turning power) and relatively high speed. Therefore, a system to support the windings and increase the strength of each winding's magnetic field is needed.

A ***starter armature*** consists of the armature shaft, armature core, commutator, and armature windings. The ***armature motor shaft*** supports the armature as it spins inside the starter housing. The commutator is mounted on one end of the armature shaft.

The ***armature core*** holds the windings in place. The armature core is made of iron to increase the strength of the magnetic field produced by the windings. Look at **Figure 31-6.**

Field Windings

A ***field winding*** is a stationary insulated wire wrapped in a circular shape. It creates a strong magnetic field around the armature. **Figure 31-6** shows a basic set of field windings.

When current flows through the field winding, the magnetic field between the pole shoes becomes very large. It can be 5–10 times that of a permanent magnet. As the magnetic field between the pole shoes acts against the field developed by the armature, the motor spins with extra power.

Starter Pinion Gear

A ***starter pinion gear*** is a small gear on the armature shaft that engages a large ring gear on the engine flywheel. It moves into and meshes with the ***flywheel ring gear*** anytime the starter is energized. In **Figure 31-7,** note the relationship of the gears.

Most starter pinion gears are made as part of a pinion drive mechanism (pinion gear, clutch, and housing). The pinion drive unit slides over one end of the armature shaft, **Figure 31-8.**

Overrunning Clutch

The ***starter overrunning clutch*** locks the pinion gear in one direction and releases it in the other. This allows the pinion gear to turn the flywheel ring gear for starting. It also lets the pinion gear freewheel when the engine begins to run.

Figure 31-9 shows a cutaway view of a pinion gear overrunning clutch assembly. Without the overrunning clutch, the starter could be driven by the engine flywheel. The flywheel gear could spin the starter too fast and cause armature damage.

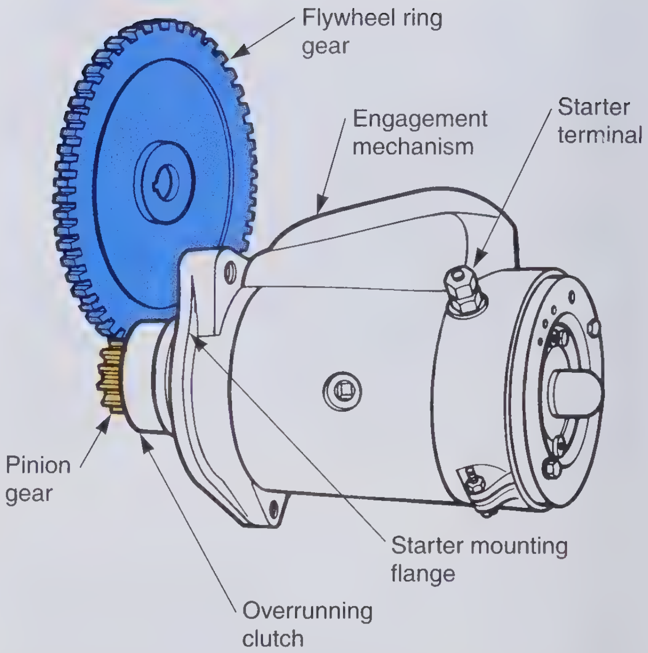

Figure 31-7. The starter pinion gear meshes with the large ring gear on the engine flywheel.

Overrunning Clutch Operation

Figure 31-10 shows the basic operation of a starter overrunning clutch. Small spring-loaded rollers are located between the pinion gear collar and the clutch shell. The rollers wedge into the notches in the shell in the driving direction. They slide back and release when driven in the other direction (freewheeling direction).

There are spiral grooves on the armature shaft and the inside diameter of the clutch. The grooves force the shaft and pinion gear assembly to turn together. They also let the gear assembly slide on the armature shaft, **Figure 31-11.**

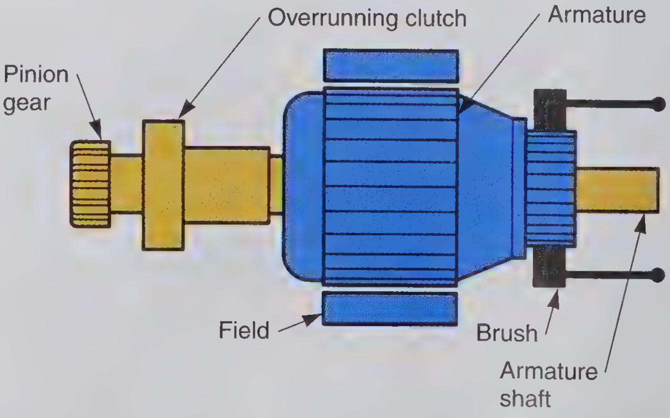

Figure 31-8. The pinion gear clutch assembly slides onto one end of the armature shaft. Note the other parts. (Robert Bosch)

Figure 31-11. The pinion gear assembly is splined to the armature shaft. This makes the pinion gear assembly turn with the shaft. It also lets pinion gear slide on the shaft for engagement with the flywheel gear. Note how this unit also has a disc brake for stopping the pinion after disengagement. (Robert Bosch)

Starter Solenoid

The ***starter solenoid*** is a high-current relay. It makes an electrical connection between the battery and the starting motor. The starter solenoid is an ***electromagnetic switch*** (switch using electricity and magnetism for operation). It is similar to other relays but is capable of handling much higher current levels.

A cutaway view of a starter solenoid is given in **Figure 31-12.** Note the solenoid windings, contact disc, terminals, plunger, and other parts.

Starter Solenoid Operation

With the ignition key in start position, a small amount of current flows through the ***solenoid windings.*** This produces a magnetic field that pulls the solenoid plunger and disc into the coil windings. This causes the

Figure 31-13. Solenoid operation. With the ignition key turned to start, current flows through the solenoid coil. This produces a field that pulls the plunger inward. As soon as the disc touches the terminals, a large amount of current flows to the starter.

solenoid disc to touch both of the high-current terminals, completing the battery-to-starter circuit. A current of 150–200 amps flows through the solenoid to the starter. Look at **Figure 31-13.**

When the ignition key is released, current is disconnected from the solenoid windings. The magnetic field collapses, and the plunger is free to slide out of the windings. This opens the disc-to-terminal connection. The open connection stops current to the starter, and the starter motor shuts off.

Starter Solenoid Functions

A starter solenoid may have three functions, depending on starter design:

- Close battery-to-starter circuit.
- Push the starter pinion gear into mesh with the flywheel ring gear.
- Bypass the resistance wire in the ignition circuit. (See Chapter 35.)

The starter solenoid may be located on the starting motor or away from it. When mounted on a body panel (away from starter), the solenoid simply makes and breaks electrical connections. When mounted on the starter, it also slides the pinion gear into the flywheel ring gear.

Starting Motor Construction

The construction of all starting motors is very similar. There are slight variations in design, however. As pictured in **Figure 31-14,** the main parts of a starting motor are:

- ***Armature***—windings, core, shaft, and commutator assembly that spins inside a stationary field.
- ***Pinion drive assembly***—pinion gear, overrunning clutch, and sometimes a shift lever and solenoid.
- ***Commutator end frame***—end housing for brushes, brush springs, and shaft bushing.
- ***Field frame***—center housing that holds field coils and pole shoes.
- ***Drive end frame***—end housing around pinion gear; has bushing for armature shaft.

Starting Motor Types

Starting motors are classified by type of pinion gear engagement. There are two main starter types: moveable pole shoe starting motors and solenoid starting motors. Both types are pictured in **Figure 31-14.**

A ***movable pole shoe starting motor*** uses a drive yoke to move the pinion gear into contact with the flywheel gear. The shoe is hinged on the starter frame with a drive yoke. The drive yoke links the pole shoe and pinion gear, **Figure 31-15.**

When the starter is activated, the magnetic field of the motor pulls the pole shoe downward. Then, lever action of the yoke pushes the pinion gear outward on its shaft. This causes gear engagement as the armature begins to spin. When the motor is shut off, a spring moves the pinion gear and pole shoe into the released position.

A ***starter-mounted solenoid*** has a plunger that moves a shift lever to engage the pinion gear. The solenoid is mounted on the side of the starter field frame, as in **Figure 31-16.** With this starter design, the solenoid completes the battery-to-starter circuit and also operates the pinion gear. **Figure 31-17** shows the basic operation of a starter-mounted solenoid.

Permanent-Magnet Starter

A ***permanent-magnet starter*** uses special high-strength magnets in place of conventional field windings. The magnets produce a strong magnetic field capable of rotating the armature with enough torque to crank the engine. A permanent-magnet starting motor is shown in **Figure 31-18.**

Starting Motor Torque

A starting motor must produce high torque to start an engine. The pinion gear is much smaller than the flywheel ring gear. Therefore, the starting motor armature turns at a relatively high speed. This helps prevent stalling of the motor. The difference in gear size also increases turning force applied to the crankshaft.

A ***reduction starter*** is sometimes used to further increase the rotating force applied to the engine flywheel.

It uses an extra set of gears to improve the gear reduction, as in **Figure 31-19.**

The starter pinion gear drives an idler gear. The idler gear drives a larger gear on the overrunning clutch assembly. This allows higher armature speed and higher torque output to the flywheel. More constant engine cranking speeds are produced by a reduction starter.

Internal Motor Circuits

Direct-current electric motors have three common types of internal connections: series, shunt, and compound. Refer to **Figure 31-20.**

Generally, ***series-wound motors*** develop maximum torque at initial start-up. Torque decreases as motor speed increases. ***Shunt-wound motors*** have less starting torque but more constant torque at varying speeds. ***Compound-wound motors*** have both series and shunt windings. They have good starting power with fairly constant operating speed.

Neutral Safety Switch

A ***neutral safety switch*** prevents the engine from cranking unless the shift selector is in neutral or park. It keeps the starting system from working when the transmission is in gear. See **Figure 31-21.** The switch provides a safety feature to prevent the car from starting while in gear.

Cars with automatic transmissions commonly have a neutral safety switch. The switch may be mounted on the shift lever mechanism or on the transmission.

To solenoid winding
Cranking motor

Figure 31-21. The neutral safety switch is in series with the starter solenoid. If it is open, the starter will not work. The shift mechanism on an automatic transmission operates the switch. (GMC)

Neutral Safety Switch Operation

The neutral safety is wired into the circuit going to the starter solenoid. When the transmission is in drive or reverse, the neutral safety switch is open (disconnected). This prevents current from activating the solenoid and starter when the ignition switch is turned to start.

With the transmission in park or neutral, the neutral safety switch is closed (connected). Current can flow to the starter when the ignition switch is turned.

Tech Tip!
In most late-model cars, the brake light switch is wired into the same control circuit as the neutral safety switch. You must have the transmission in park (or neutral) and press the brake pedal for the starting motor to energize.

Starter Relay

As you learned in the chapter on electricity and electronics, a ***relay*** is a device that opens or closes one circuit by responding to an electrical signal from another circuit. Some starting systems use a relay between the ignition switch and the starter solenoid.

A ***starter relay*** uses a small current flow from the ignition switch to control a slightly larger current flow to the starter solenoid. This further reduces the load on the ignition key switch.

Starter Relay Operation

A starter relay circuit is shown in **Figure 31-22.** When the ignition switch is turned to start, current flows into the relay. This closes the relay contacts. The contacts complete the circuit to the solenoid windings and the starting system operates.

When the key is released, the relay opens. This stops the solenoid current to disengage the starting motor.

Highway History

The first motorcars were as hard to start as they were to drive. Early cars were started by turning a crank connected to the engine's crankshaft. Not only was the crank difficult to turn, but it could also be very dangerous. It was not uncommon for a motorist to break an arm or a wrist when the crank "kicked back" during an engine backfire.

The first electric "self-starter" was invented by Charles Kettering and introduced on the 1912 Cadillac. This invention is considered by many to be one of the most important steps in transforming the "horseless carriage" into a practical and reliable means of transportation.

Summary

- The starting system uses battery power and an electric motor to turn the engine crankshaft for engine starting.
- The starting motor converts electrical energy from the battery into mechanical or rotating energy to crank the engine.
- The commutator serves as a sliding electrical connection between the motor windings and the brushes.
- A field winding is a stationary set of windings (insulated wire wrapped in circular shape).
- A starter pinion gear is a small gear on the armature shaft that engages a large ring gear on the engine flywheel.
- The starter overrunning clutch locks the pinion gear in one direction and releases it in the other.
- The starter solenoid is a high-current relay. It makes an electrical connection between the battery and starting motor.
- A permanent-magnet starter uses special high-strength magnets in place of conventional field windings.
- A reduction starter is sometimes used to further increase the rotating force applied to the engine flywheel.
- A neutral safety switch prevents the engine from cranking unless the shift selector is in neutral or park.
- A starter relay uses a small current flow from the ignition switch to control a slightly larger current flow to the starter solenoid.

Review Questions—Chapter 31

Please do not write in this text. Place your answers on a separate sheet of paper.

1. List and describe the four major parts of a starting system.
2. The _____ _____ converts electrical energy from the battery into mechanical or rotating energy to crank the engine.
3. Like charges (fields) attract each other and unlike charges (fields) repel each other. True or False?
4. The _____ serves as a sliding electrical connection between the motor windings and the brushes.
5. Which of the following is *not* part of a starting motor?
   (A) Armature.
   (B) Field winding.
   (C) Commutator.
   (D) Slip ring.
6. What is the function of the starter pinion gear?
7. What would happen if the starting motor did *not* have an overrunning clutch (gear locked to armature shaft)?

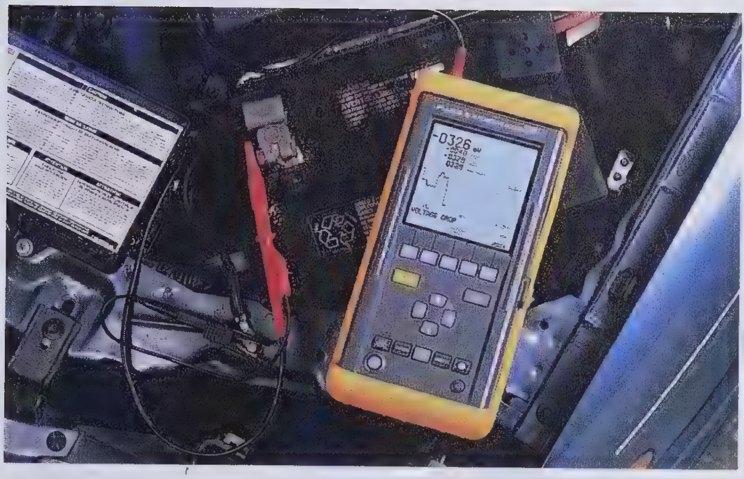
8. The _____ _____ is a high current relay that completes the circuit between the battery and the starting motor.
9. List three functions of a starter solenoid.
10. List and explain the five major parts of a starting motor.
11. Describe the two main types of starting motors.
12. Why is a reduction starting motor sometimes used?
13. Which of the following is *not* a type of internal starting motor circuit?
    (A) Parallel wound.
    (B) Series wound.
    (C) Shunt wound.
    (D) Compound wound.
14. The _____ _____ _____ keeps the engine from cranking unless the shift selector is in neutral or park.
15. A starter relay uses a small current flow from the ignition switch to control a slightly larger current flow to the _____ _____.

ASE-Type Questions

1. Which of the following converts electrical energy from the battery into mechanical or rotating energy to crank the engine?
    (A) Solenoid.
    (B) Pinion gear.
    (C) Starting motor.
    (D) All of the above.
2. Magnetic fields that are *alike* will:
    (A) repel each other.
    (B) cancel each other.
    (C) attract each other.
    (D) None of the above.
3. Which of the following serves as a sliding electrical connection between motor windings and brushes?
    (A) Solenoid.
    (B) Armature.
    (C) Pole piece.
    (D) Commutator.
4. A starter armature consists of each of these *except:*
    (A) shaft.
    (B) flange.
    (C) windings.
    (D) commutator.
5. Which device locks a pinion gear in one direction and releases it in the other?
    (A) Roller retainer.
    (B) Starter solenoid.
    (C) Flywheel ring gear.
    (D) Overrunning clutch.
6. A starter solenoid is this type of relay switch.
    (A) Electric.
    (B) Magnetic.
    (C) Electromagnetic.
    (D) None of the above.
7. Which of the following is *not* a starter solenoid function?
    (A) Controls electric motor spinning.
    (B) Closes battery-to-starter circuit.
    (C) Pushes pinion gear into flywheel gear.
    (D) Bypasses ignition circuit resistance wire.
8. When reviewing starter motor classifications, Technician A says starters are grouped by type of pinion gear engagement. Technician B feels starters are grouped by type of internal connections they have. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
9. Which of the following uses a plunger to move a shift lever that engages the pinion gear?
    (A) Reduction starter.
    (B) Movable pole shoe.
    (C) Starter-mounted solenoid.
    (D) Permanent-magnet starter.
10. Which of the following uses a small current flow from the ignition switch to control a larger current flow to the starter solenoid?
    (A) Clutch.
    (B) Starter relay.
    (C) Reduction starter.
    (D) None of the above.

Activities—Chapter 31

1. If possible, obtain an unserviceable starter motor from a shop or junkyard. Carefully disassemble and clean the components. Mount and label them for a classroom display.
2. Find out the advantages and disadvantages of installing a rebuilt starter (rather than a new one) in a vehicle. Report to the class.



32

Starting System Testing and Repair

After studying this chapter, you will be able to:

- Diagnose common starting system troubles.
- Make orderly starting system tests.
- Remove and replace a starting motor.
- Explain typical procedures for a starting motor rebuild.
- Adjust a neutral safety switch.
- Describe the safety practices that should be followed when testing or repairing a starting system.
- Correctly answer ASE certification test questions on starting system diagnosis, service, and repair.

This chapter introduces the steps for diagnosing, testing, and repairing common starting system problems. It begins by explaining on-car diagnosis. Then, it details the service of each component.

By studying this chapter, you will learn to recognize the symptoms of faulty starting system components. You will also learn how to check and verify the operation of each component, as well as how to remove, repair, and replace faulty components.

Starting System Diagnosis

The starting system is easier to troubleshoot and repair than a car's other electrical systems. It has only a few major components that can cause problems, **Figure 32-1.** If any of these parts have high resistance, lower-than-normal resistance, damage, or wear, the engine may not crank normally.

Common Starting System Problems

In a ***no-crank problem,*** the engine crankshaft does not rotate when the ignition key is turned to the start position. The most common causes are a dead battery, poor electrical connection, or faulty system component.

A ***slow-cranking condition*** occurs when the engine crankshaft rotates at speeds that are lower than normal. This condition is usually caused by the same kinds of faults that produce a no-crank problem.

If a *solenoid buzzing* or *clicking* sound (engine not cranking) occurs when the key is turned to start, the battery may be discharged or the battery cable connections may be poor. Low current flow causes the solenoid plunger to rapidly kick in and out, making a clicking or buzzing sound. A single solenoid click sound without engine cranking may point to a bad starting motor, burned solenoid contacts, a partially discharged battery, or engine mechanical problems. The click is usually the solenoid closing or the pinion gear contacting the flywheel gear.

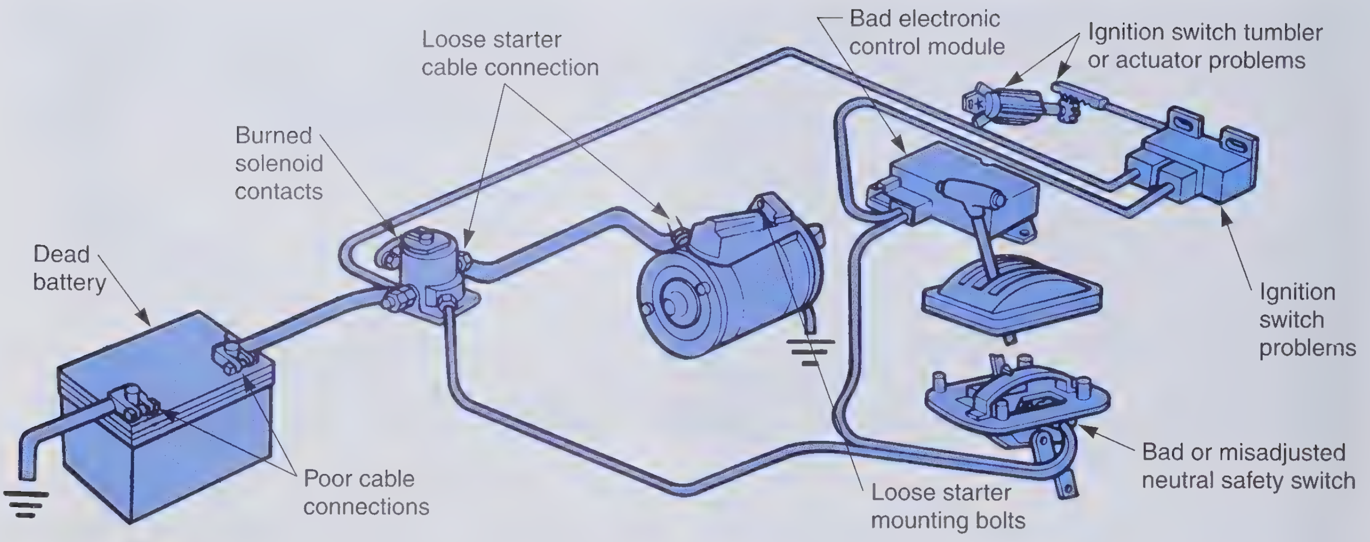
A *humming sound* that occurs after momentary engine cranking may be due to a bad overrunning clutch or a worn pinion gear unit. Pinion gear wear can make the gear disengage from the flywheel gear too soon. This can let the motor armature spin rapidly, producing a humming sound.

A *metallic grinding noise* may be caused by broken flywheel teeth or worn pinion gear teeth. The grinding may be caused as the gears clash against each other.

Normal cranking without starting is usually not caused by the starting system. There may be trouble in the fuel or ignition systems. With a diesel engine, check engine cranking speed. If cranking speed is low, the diesel may not start.

Tech Tip!

Sometimes the starting solenoid feeds current to the ignition system after the engine has started. If the engine starts and then dies (stops running) as the ignition key is released, check the voltage from the solenoid to the ignition system. You could have an open wire or an open connection in the solenoid circuit. A defective ignition switch or a wiring problem are other possible causes.



Loose starter cable connection
Bad electronic control module
Ignition switch tumbler or actuator problems
Burned solenoid contacts
Dead battery
Ignition switch problems
Poor cable connections
Loose starter mounting bolts
Bad or misadjusted neutral safety switch

Figure 32-1. During initial inspection, check for these kinds of starting system troubles. A loose connection or discharged battery could keep engine from cranking.

Starting Headlight Test

A ***starting headlight test*** will quickly indicate the causes of trouble in a starting system. Turn on the headlights and try to start the engine. Note any sounds and watch the brightness of the headlights.

No cranking with no headlights points to a dead battery or an open in the electrical system. The battery connections may be bad. A burned fusible link will also kill power to most systems, **Figure 32-2.** A main feed wire to the fuse box could also be broken or disconnected.

If the headlights go out when cranking, the battery may be weak. The starting motor may be shorted. The engine could also be at fault. Dimming headlights indicate heavy current draw or poor current supply from the battery.

If the lights stay bright but the engine does not crank properly, a high resistance or an open in the starting circuit is likely. The problem could be in the ignition switch, wiring, solenoid, starter cable connections, or relay.

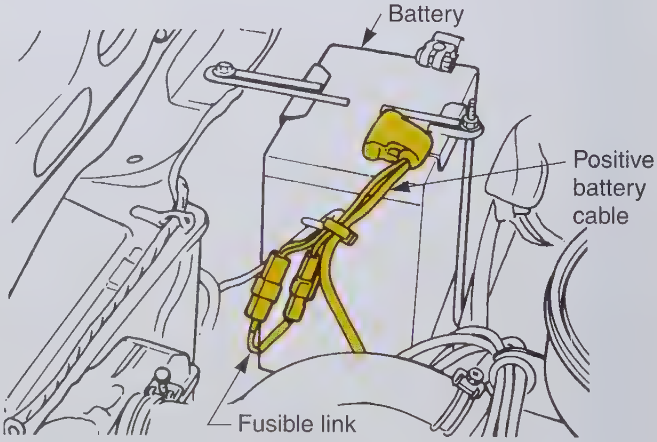
Depending on what the headlights and starter do when testing, you can decide what further tests are needed.

Using Service Manual Troubleshooting Charts

Service manual troubleshooting charts should be used when the causes of problems are hard to find. These charts are designed for the exact circuit and will often reduce the list of causes.

Checking the Battery

A dead or discharged battery is one of the most common reasons the starting system fails to crank the engine properly. The starting motor draws much more current (over 200 amps) than any other electrical component. A discharged or poorly connected battery can operate the lights, but it may not have enough power to operate the starting motor.



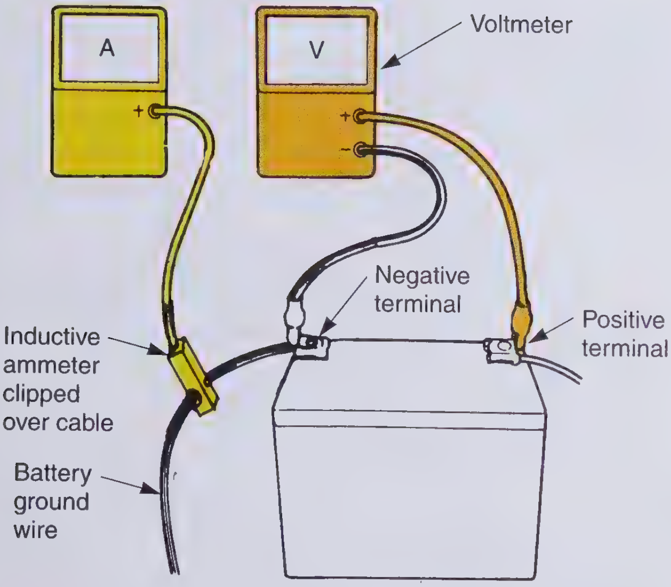
Battery
Positive battery cable
Fusible link

Figure 32-2. The battery and its cables are the most common cause of improper cranking. Note the fusible link attached to the positive battery cable. It can burn during a short to protect the electrical system. If major components (lights, horn, starting system) are dead, check the fusible link. (Mazda)

If needed, load-test the battery as described in the chapter on battery service. Make sure the battery is in good condition and is fully charged. A starting motor will not function without a fully charged and well-connected battery.

Starter Current Draw Test

A ***starter current draw test*** measures the current used by the starting system. It will quickly tell you about



A
V
Voltmeter
+
+
–
Negative terminal
Positive terminal
Inductive ammeter clipped over cable
Battery ground wire

Figure 32-3. A voltmeter and an ammeter can also be used to measure starter current draw. A voltmeter reading is needed to compare different battery conditions. If current draw is not within specifications, there are starting system troubles. (Honda)

the condition of the starting motor and other system parts. If current draw is higher or lower than specifications, there is a problem.

To perform a current draw test, connect meters to measure the battery voltage and the current flow out of the battery. A load tester may also be used. Two testing methods are shown in **Figures 32-3** and **32-4.**

To keep the engine from starting during the test, disconnect the coil primary supply wire or ground the coil wire. You can also pull the fuse for the electric fuel pump if this is easier (direct ignition systems). Look at **Figure 32-5.**

With a diesel engine, you must disable the injection system. You may have to unhook the fuel shutoff solenoid. Check a shop manual for details.

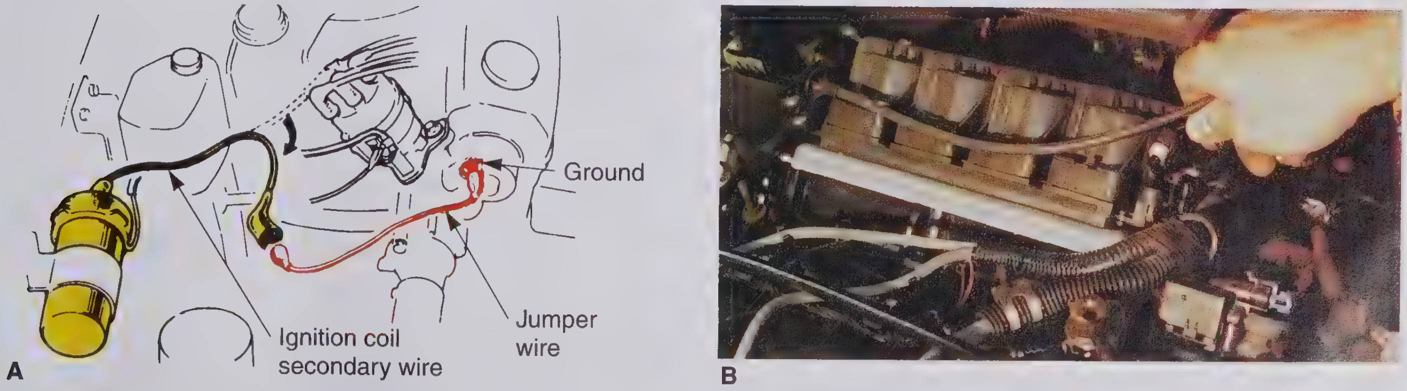
Figure 32-4. A battery load tester can be used to check the starter current draw. Crank the engine and note the voltage reading. Then, load the battery to obtain the same voltage. This will equal the current draw of starting motor. (DaimlerChrysler)



Ground
Jumper wire
Ignition coil secondary wire
A
B

Figure 32-5. To keep the engine from running during a starter current draw test, disable the ignition system. (Honda) A—If a distributor is used, you can ground the coil wire. B—With a coil pack, disconnect the primary wires to disable the system.

Caution!
Do not crank the engine for more than 15–30 seconds or starter damage may result. If cranked too long, the starter could overheat. Allow the starter to cool for a few minutes if more cranking time is needed.

Crank the engine and note the voltage and current readings. If they are not within specifications, something is wrong in the starting system or engine. Further tests are needed. **Figure 32-6** contains a troubleshooting chart and gives the average current draw values for various engine sizes.

Starting System Voltage Drop Tests

Voltage drop tests will quickly locate a part with higher-than-normal resistance. These tests provide an easy way of checking circuit condition. You do not need to disconnect wires and components to check internal resistance (voltage drops).

Insulated Circuit Resistance Test

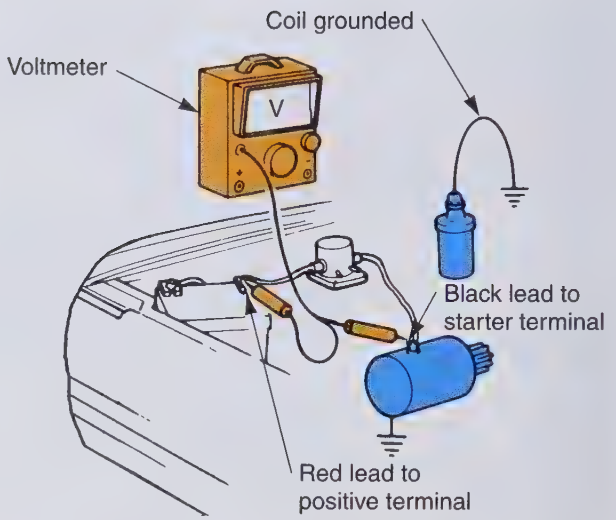
An ***insulated circuit resistance test*** checks all parts between the positive battery terminal and the starting motor for excess resistance. **Figure 32-7** shows the basic connections for this test. Touch your voltmeter probes on the positive battery terminal and the starting motor input terminal.

ENGINE DISPLACEMENT	12-VOLT SYSTEM MAX. CURRENT
Most 4–6 Cylinders	125–175 Amps Max.
Under 300 C.I.D.	150–200 Amps Max.
Over 300 C.I.D.	175–250 Amps Max.

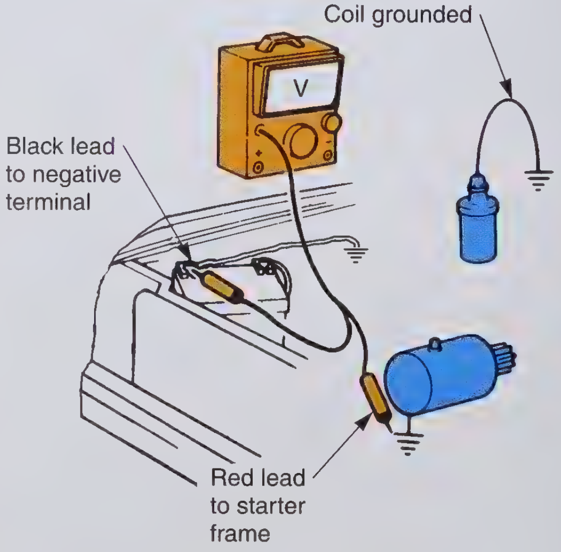
CRANKING CIRCUIT TROUBLESHOOTING CHART

Cranking Voltage	Cranking Amps	Possible Problem
Voltage OK	Current OK	System OK
Voltage OK	Current Low Engine Cranks Slowly	Starter Circuit Connections Faulty
Voltage Low	Current Low Engine Cranks Slowly	Battery Low
Voltage Low	Current High	Starter Motor Faulty

Figure 32-6. This chart shows typical current draw values for different engine sizes. Ignore initial readings until the engine has cranked for a few seconds. Then current draw will stabilize. Study meter readings and trouble chart. (Marquette)



Insulated circuit resistance test



Starter ground circuit test

Figure 32-7. Voltage drop tests are a quick way of checking circuit resistance without disconnecting wires. (DaimlerChrysler)

Disable the ignition or injection system; then crank the engine. The voltmeter should not read over 0.5 volts. If voltage drop is greater, there is excess resistance in the circuit. There may be loose electrical connections, burned or pitted solenoid contacts, or other problems. Test each part individually.

Starter Ground Circuit Test

A ***starter ground circuit test*** checks the circuit between the starting motor ground and the negative battery terminal. Look at **Figure 32-7.** Touch the voltmeter leads to the battery negative terminal and the starter end frame. Crank the engine and note the meter reading. If the reading is higher than 0.5 volts, check the voltage drop across the negative battery cable. The engine may not be grounded properly. Clean, tighten, or replace the cable as needed.

Battery Cable Service

A battery cable problem can produce symptoms similar to those caused by a dead battery, bad solenoid, or weak starting motor. If the cables do not allow enough current flow, the starter will turn slowly or not at all.

Warning!
Never remove starting system parts without disconnecting the battery. The engine could be cranked over, causing injury. Also, an electrical fire could result if wires are shorted.

Testing Battery Cables

To do a ***battery cable connection test,*** connect a voltmeter to the battery post and to the cable. See **Figure 32-8.** Measure the voltage drop across the connections while cranking the engine. If any cable shows a high voltage drop (above 0.3 volts) during cranking, clean and tighten its connections. Then retest the cable. If the voltage drop is still high, replace the cable.

Replacing Battery Cables

When replacing battery cables, make sure the new cables are the same as the old ones. Compare cable length and diameter. Lead terminals are better than steel terminals. The soft lead will conform to the shape of the battery terminal easier.

Caution!
When tightening the connections on the ends of battery or starter cables, only snug down the fasteners. Many of the threaded studs, bolts, and nuts are made of soft lead or brass. They can strip and break easily.

Starter Solenoid Service

A bad starter solenoid can cause a variety of problems, including no cranking (with or without a click) or slow cranking. It can also keep the engine and starting motor running or prevent the starting motor from disengaging from the engine.

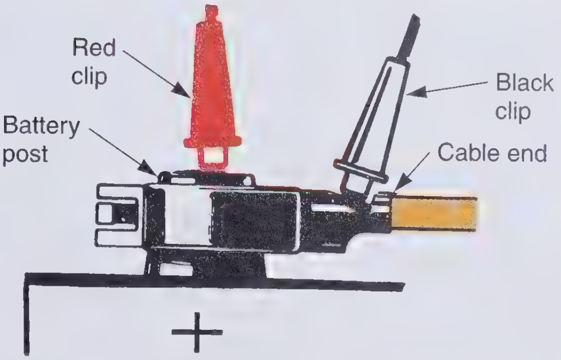


Figure 32-8. Checking battery terminals for corrosion and high resistance by measuring voltage drop.

Usually, the large disc-shaped contact will burn and pit. The disc can develop high resistance that reduces current flow to the starter. An open or shorted solenoid winding can keep the contact disc from closing. No click will occur and the engine will not crank.

Testing the Starter Solenoid

To test the solenoid, connect a voltmeter as shown in **Figure 32-9.** This will measure the voltage drop and resistance of the solenoid lugs and contacts. Crank the

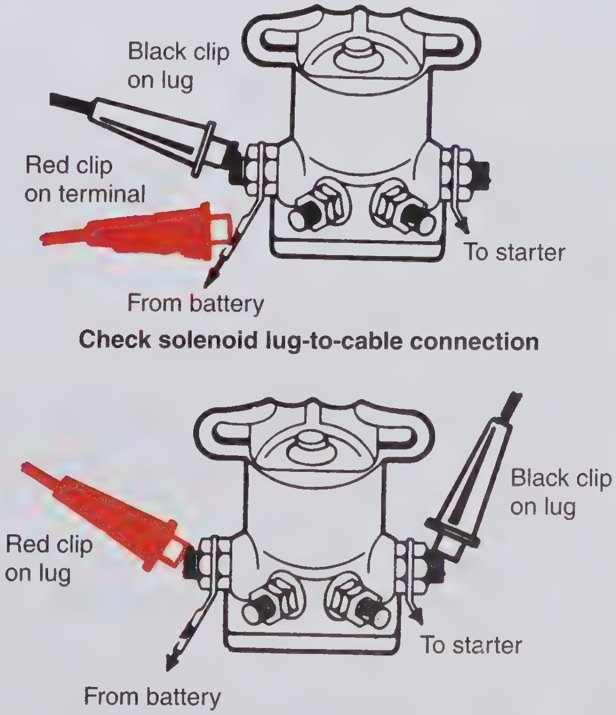

Figure 32-9. Checking the starter solenoid. (Marquette)

engine and note the voltmeter reading. If either voltage measurement is above 0.3 volts, tighten the cable connections or replace the solenoid.

Replacing the Starter Solenoid

To replace a solenoid that is mounted away from the starter, simply remove the cables and wires. Unbolt the solenoid from the fender well and install the new one.

If the solenoid is a starter-mounted unit, the starter must be removed from the engine. Then, the solenoid is unscrewed from the starting motor and replaced. The procedures for removing, assembling, and installing a starter are covered later.

Warning!
Before disconnecting the positive cable from a starter solenoid, make sure the battery has been disconnected. If you short this cable to ground, a powerful electric short will result. This could damage parts or cause burns.

Ignition Switch Service

A bad ignition switch (starter feed section of switch) can keep the starter solenoid from working normally. It can also keep the solenoid from releasing. The contacts in the ignition switch can wear or burn, causing either an open (no-cranking problem) or a short (engine cranks all the time).

Testing the Ignition Switch

To test an ignition switch, touch a test light to the starter solenoid start (S) terminal. If the ignition switch is good, the test light will glow when the key is turned to start the engine. The test light should go out when the key is released.

If the test light on the solenoid does not glow, either a wire in the ignition switch circuit is open or the ignition switch is defective. Test the wires coming out of the ignition switch to eliminate the possibility of a bad wire.

If the test light on the solenoid glows in both the start and run positions, the ignition switch is probably shorted. The engine would crank all the time.

These are simplified tests. You will need to use your own judgment and a service manual to perform more detailed tests.

Note!
For more information on ignition switch service, refer to Chapter 36, *Ignition System Problems, Testing, and Repair.*

Starter Relay Service

A bad starter relay will keep power from the starter solenoid. This will prevent engine cranking. The winding or the contact points in the relay could be faulty. If the relay is bad, you will not hear the solenoid click and engage.

To test a starter relay, use a test light to check for voltage going into and coming out of the relay terminals. Refer to a wiring diagram for test points. Replace the relay if needed.

Neutral Safety Switch Service

A misadjusted or bad neutral safety switch can also keep the engine from cranking when the key is turned to start. If the neutral safety switch is open, current cannot flow from the ignition switch to the starter solenoid.

Checking the Neutral Safety Switch

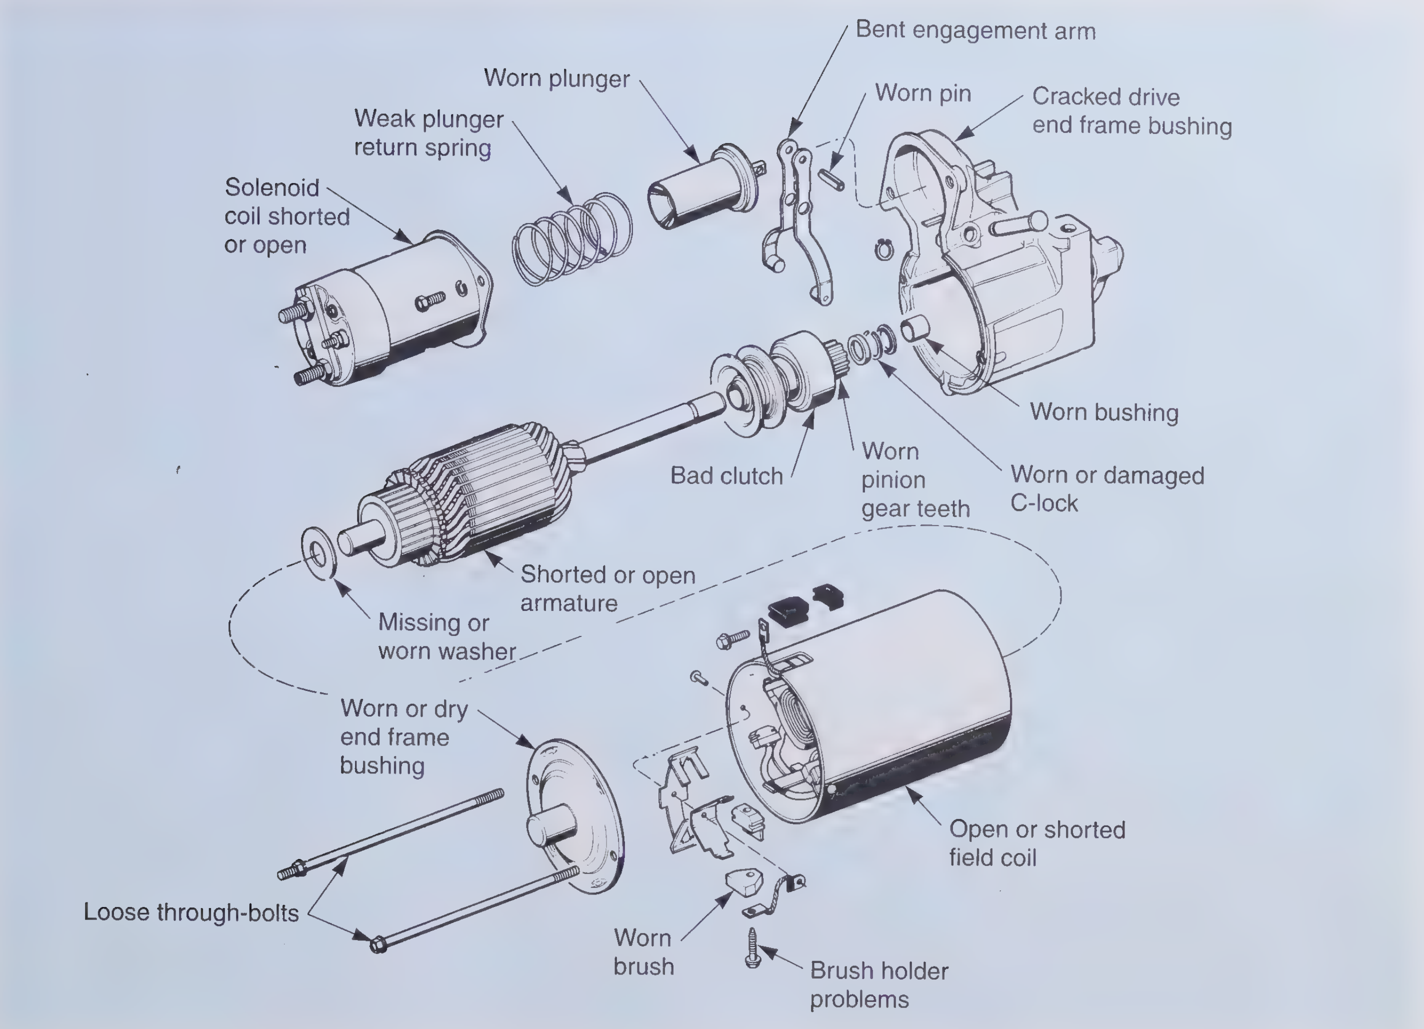
Before testing the switch, move the transmission gear shift lever into various positions while trying to start the engine. The switch may close, letting the starter operate. If the starter begins to work, the neutral safety switch may only need adjustment.

Warning!
Make sure to press down on the vehicle's brake pedal when checking a neutral safety switch. If the switch is worn or faulty, the engine could try to start while the vehicle is in drive or reverse. If this happens, the brakes would be needed to keep the vehicle from moving.

Adjusting the Neutral Safety Switch

The procedure for adjusting a neutral safety switch is fairly simple:

1. Loosen the fasteners holding the switch. The switch may be located on the steering column, shift lever, or transmission.
2. With the switch loosened, place the shift selector into park.
3. While holding the ignition switch to start, slide the neutral switch on its mount until the engine cranks.
4. Without moving the switch, tighten its hold-down screws. This should allow the engine start only with the shift lever in park or neutral.
5. Check operation after adjustment.



Bent engagement arm
Worn plunger
Worn pin
Cracked drive end frame bushing
Weak plunger return spring
Solenoid coil shorted or open
Worn bushing
Bad clutch
Worn pinion gear teeth
Worn or damaged C-lock
Shorted or open armature
Missing or worn washer
Worn or dry end frame bushing
Open or shorted field coil
Loose through-bolts
Worn brush
Brush holder problems

Figure 32-10. Study the types of problems requiring starting motor repairs.

Testing the Neutral Safety Switch

To test a neutral safety switch, touch a 12-volt test light to the switch output wire connection while moving the transmission shift lever. The light should glow as the shift lever is slid into park and neutral. The test light should not glow when the shift lever is in other positions.

Check the mechanism that operates the neutral safety switch. There should be a prong or other device that actuates the neutral safety switch. If the problem is in the switch, remove, replace, and adjust it.

Starter Service

A faulty starting motor can cause a wide range of symptoms: slow cranking, no cranking, overheating of starter cables, and abnormal noises while cranking. If the battery, cables, solenoid, and other starting system parts are good but the engine does not crank properly, the starter may be bad.

A current draw test and other tests will help you determine whether the starting motor should be removed for further inspection and testing.

Figure 32-10 shows an exploded view of a typical starter. Study the types of problems that can occur and require a motor rebuild.

Starting Motor Rebuild

A ***starting motor rebuild*** typically involves:

1. Removing and disassembling the starting motor.
2. Cleaning parts and inspecting them for wear or damage.
3. Replacing brushes, bushings, and other worn or damaged parts.
4. Polishing or turning the commutator.
5. Lubricating, reassembling, testing, and installing the starting motor.

Many shops do not rebuild starting motors. They purchase and install new or factory-rebuilt units. The cost of labor is too high to make in-shop rebuilding economical. Also, the factory-rebuilt units will have a limited warranty.

Tech Tip!
When the starter must be repaired, you may only need to disassemble a section of the starter. For example, a worn pinion gear can make the starter disengage before engine start-up. The clutch will freewheel before the engine has cranked. The pinion gear assembly can be replaced without complete starting motor disassembly. By removing only the drive-end frame and a C-lock, the brushes and the other end of the motor can usually be left together.

Starting Motor Removal

Before deciding to remove the starting motor, inspect it closely for problems. Check that the starter-to-engine bolts are tight. Loose starter bolts can upset motor operation by causing a poor ground or incorrect pinion gear meshing. Make sure all wires on the motor and solenoid are tight.

If no obvious problems are found, the starter should be removed. To remove a starter:

1. Disconnect the battery.
2. Unbolt the battery cable, solenoid wires (starter-mounted solenoid type), and any braces on the motor, **Figure 32-11.**
3. Unscrew the bolts while holding the motor. Look at **Figure 32-12.**

Starter shims may be used to adjust the space between the pinion gear and the flywheel ring gear. During starter removal, always check for shims. They must be returned to the same place during reassembly. If the shims are not replaced, the pinion and flywheel gears will not mesh properly. A grinding noise will result, and the pinion and flywheel gears may be damaged.

Tech Tip!
In a few late-model engines, the starting motor is located under the engine intake manifold. See **Figure 32-13.** You must remove the manifold to service the starting motor on these engines. Usually, only a few easy-to-reach bolts secure the intake manifold.

Starter Disassembly

After the starter is removed, it must be disassembled. Refer to **Figure 32-14.**

1. If the starter has a solenoid, remove the fasteners that hold it in place.
2. Pull the solenoid off the motor using care not to lose the plunger spring. You may need to rotate the solenoid slightly.
3. After punch-marking the end frames, remove the through-bolts.
4. Tap off the end frames with a plastic hammer while noting the positions of the internal parts.
5. Slide the armature out of the field frame after removing the end frames.

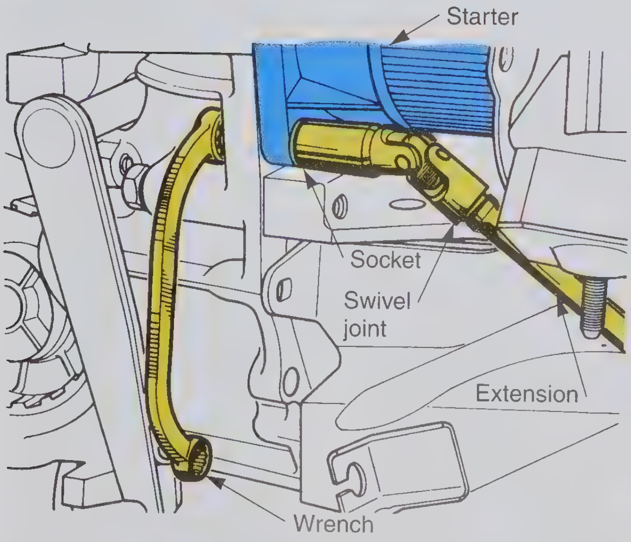


Figure 32-11. When starting motor fasteners are hard to reach, a swivel, extension, and ratchet may help. (DaimlerChrysler)

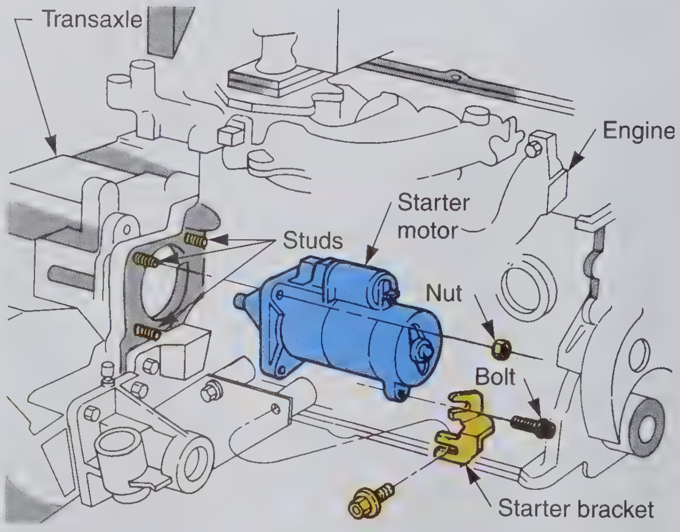

Figure 32-12. To repair a starter, remove fasteners, wires, and brackets or heat shields. Hold the starter firmly because it is fairly heavy. (DaimlerChrysler)

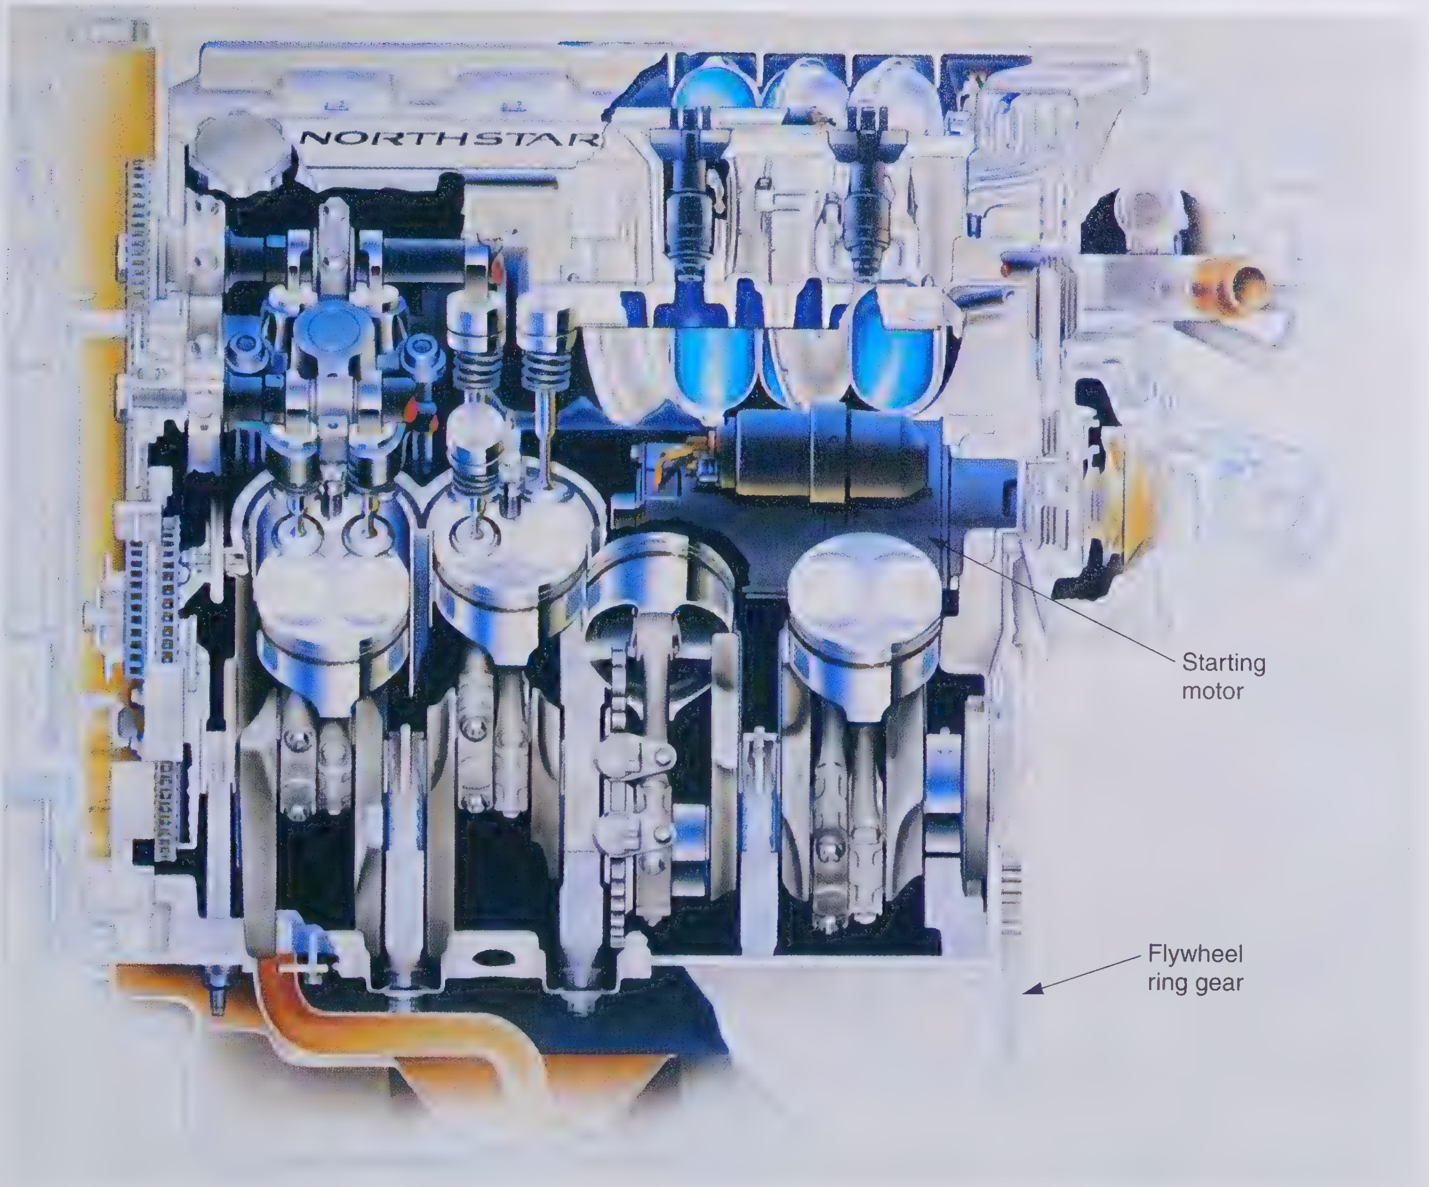

Figure 32-13. A starting motor mounted inside the valley of a V-8 engine. To get at the starting motor, you must remove the intake manifold. You can then gain easy access to the starting motor. (Cadillac)

6. Remove the C-clip holding the pinion gear on the armature shaft. Then slide the pinion gear off the shaft.

Place all the parts in an organized pattern on your workbench. This will help you if you forget how to put something together.

Inspecting Starter Motor Parts

After the starter has been disassembled, the parts should be inspected. Blow all the parts clean with compressed air. Wear eye protection.

Wipe the armature, field windings, brushes, and overrunning clutch with a clean, dry cloth. These parts should *not* be cleaned using solvent. The solvent can damage the wire insulation, soak into the brushes, or wash the lubricant out of the clutch. Once all the parts are clean and dry, inspect them for wear.

Starter Brush Service

Check for worn starter brushes, which can reduce starter torque and cause excessive starter current draw. Some manufacturers recommend a minimum length for the brushes. Measure the brushes as shown in **Figure 32-15.** If worn shorter than specifications, the brushes must be replaced.

Figure 32-14. Basic steps for starter disassembly. (DaimlerChrysler)

The brush wire leads are usually soldered in place. A soldering gun and rosin-core (not acid-core) solder must be used when replacing the brushes. Also, check the brush holder for shorts to ground, **Figure 32-15.**

Armature Service

Inspect the armature for wear and damage. Look for signs of burning or overheating on the windings and commutator. If the armature has been rubbing on a field pole shoe, the shaft may be bent. Also, check the ends of the shaft for wear and burrs.

To check for an armature short circuit, mount the armature on a ***growler*** (armature tester). This is shown in **Figure 32-16.**

After reading the instructions for the growler, turn on the power. Hold a thin strip of metal or hacksaw blade

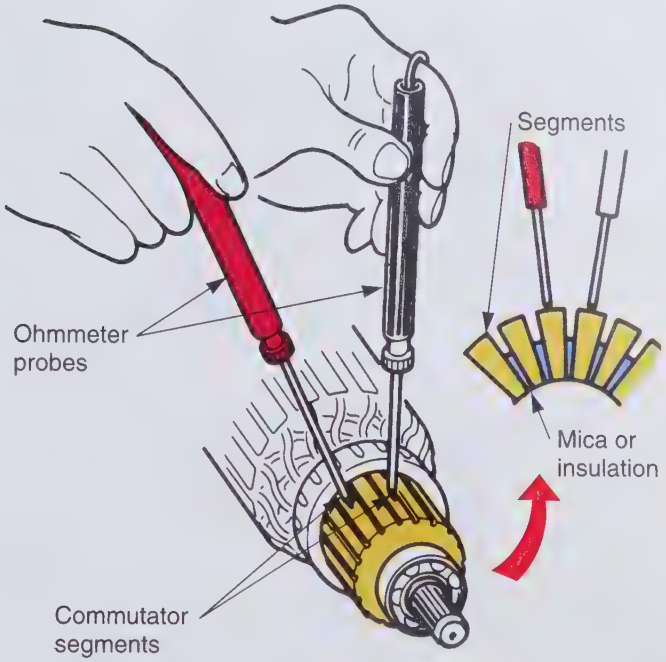
next to the armature while rotating the armature in the growler. The metal strip or hacksaw blade will vibrate when passed over the shorted leg of the windings.

To check armature continuity, do an open-circuit test. You can use a growler with an integral meter or an ohmmeter. Follow the directions provided with the test equipment.

When using an ohmmeter, touch the meter leads to each commutator segment, as in **Figure 32-17.** If the meter reads infinite resistance on any segment, that segment winding is open. The armature must be replaced.

You should also check for an armature ground (short from winding to shaft or core). This test is illustrated in **Figure 32-18.**



Segments
Ohmmeter probes
Mica or insulation
Commutator segments

Figure 32-17. An ohmmeter is used to check armature continuity. If open or infinite resistance exists between any commutator segment, replace the armature. (Honda)

Touch the ohmmeter leads on the armature coil core and the commutator segments. Repeat this test on the commutator segments and armature shaft. If there is continuity (low resistance), then the armature is grounded and must be replaced.

If the windings are in good condition, the commutator should be cleaned using very fine sandpaper, not

emery cloth. If the commutator is badly worn, it should be turned (machined) on a lathe. See **Figure 32-19.**

Then, the mica (insulation) between each commutator segment may need to be undercut. A special tool or a hacksaw blade can be used to cut the mica lower than the surface of the segments.

Also check the armature shaft. If there are any burrs at the lock ring groove, file them off.

Field Coil Service

Inspect the field windings inside the starter frame. Look for signs of physical damage or burning. To test for open field coils, use a battery-powered test light or an ohmmeter. Look at **Figure 32-20.** Touch the test leads to wires or brushes that connect to the field windings. This connection may vary with some starters, so refer to a manual.

Pinion gear

Figure 32-21. Checking starter pinion gear action. The overrunning clutch should turn freely in one direction. It should lock in the other direction. The unit should also slide freely on the armature shaft splines. Most mechanics install a new pinion gear during starter service. (Honda)

If the test light glows or the ohmmeter reads zero, the field windings are not open. If the test light does not glow or the meter indicates infinite (maximum) resistance, the field windings are open (broken) and must be replaced.

To test for grounded field coils (winding shorted to the frame or other starter component), touch the test light or ohmmeter leads across the field coil and ground. Look at **Figure 32-20.**

The light should not glow or the meter should read infinite resistance. If the starter has a shunt winding, disconnect it before making the test. If a winding is grounded, it must be replaced.

Overrunning Clutch (Pinion Gear) Service

Normally, the overrunning clutch or pinion gear assembly is replaced anytime the starting motor is disassembled. The pinion gear is subjected to extreme wear when engaged and disengaged from the engine flywheel. It is usually wise to replace the pinion gear during starter service.

If the pinion gear is to be reused, check the ends of the gear teeth for wear. See **Figure 32-21.** Also, check the action of the overrunning clutch. It should let the gear turn freely in one direction but lock the gear in the other direction.

Starter Reassembly

Reassemble the starter using the reverse order of disassembly. Lubricate the armature shaft bushings, pinion gear splines, and other parts as recommended by the manufacturer.

Caution!
Do not use too much oil or grease to lubricate the bushings and other parts of a starting motor. If lubricant gets on the brushes and commutator, starter motor power and service life will be reduced.

Brush installation is the only part of starter reassembly that may be difficult. With many starters, the brushes can be locked out of the way using the brush springs. The springs are wedged on the sides of the brushes. They will hold the brushes up so you can slide the armature and commutator into place. Then, the brushes can be pushed down and snapped into place on the commutator.

Study **Figures 32-22** and **32-23.** They show exploded views of modern starting motors.

After reassembly, test the starter before mounting it on the engine. As pictured in **Figure 32-24,** connect the starter to a battery using jumper cables. Connect the positive cable first; then connect the negative cable. Hold or clamp the starter firmly because it will lurch and rotate when energized. Make sure the motor spins at the correct speed and that the pinion gear moves into the correct position.

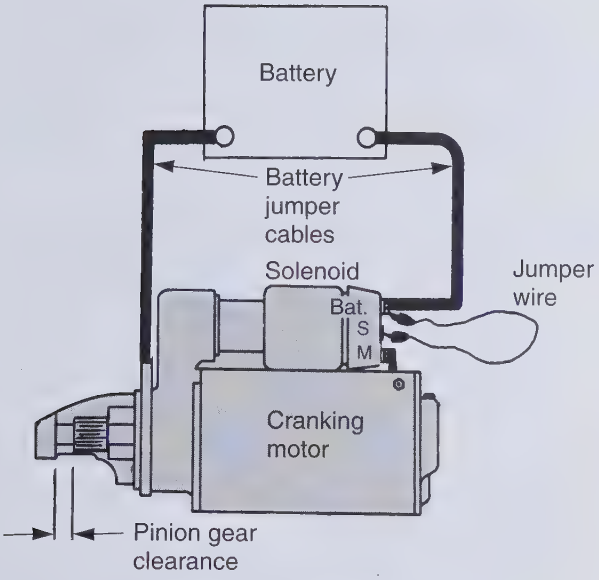

Figure 32-24. After starter repairs, bench test the motor. Connect a battery to the starter and check operation. Secure the starter because it can lurch when engaged. (Buick)

Starter pinion gear clearance is the distance between the pinion and the drive end frame with the pinion engaged. Always check pinion gear clearance during a starter bench test. With the starter energized, check the clearance as shown in **Figure 32-25.**

If pinion gear clearance is not within specs, bend the shift lever or replace the worn parts. Check a service manual for exact specifications and procedures.

Starting Motor Installation

Install the starter in the reverse order of removal. Make sure that any spacer shims are replaced between the motor and the engine block. If these shims are left out, the pinion gear may not mesh with the flywheel gear properly. Refer to **Figure 32-26.**

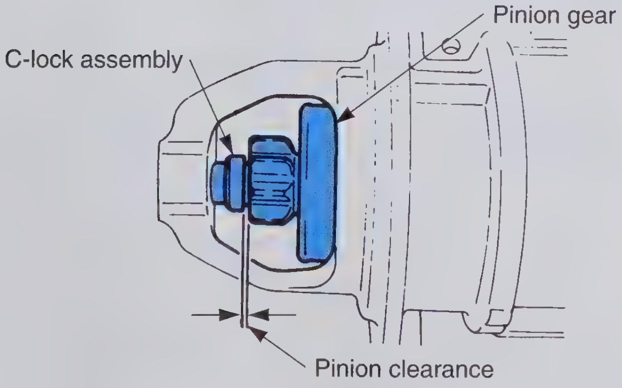

Figure 32-25. Before installing a starter, always check the pinion gear clearance. If pinion does not slide out far enough, it will not engage the flywheel ring gear properly. (Nissan)

If the starter has a solenoid on it, connect the wires on the solenoid before bolting the starter to the engine. Torque the starter bolts to specifications. Replace any brackets or shields and reconnect the battery. Crank the engine several times to check starting motor operation.

Duff's Garage

Problem: Mr. Figueroa stopped by the shop with a question about his car. "My engine just won't turn over," he says. "It will click, but nothing happens!" Duff explains that it is impossible to diagnose the problem without looking at the vehicle. Mr. Figueroa agrees to have the vehicle towed to the shop for a proper diagnosis.

Diagnosis: After pushing the car into the shop, Duff turns the key to start in an attempt to verify the problem. As Mr. Figueroa explained, the starter clicks but the starting motor does not turn the engine over. Duff suspects that the problem is a faulty solenoid on the starting motor and assigns the job to one of his apprentice technicians.

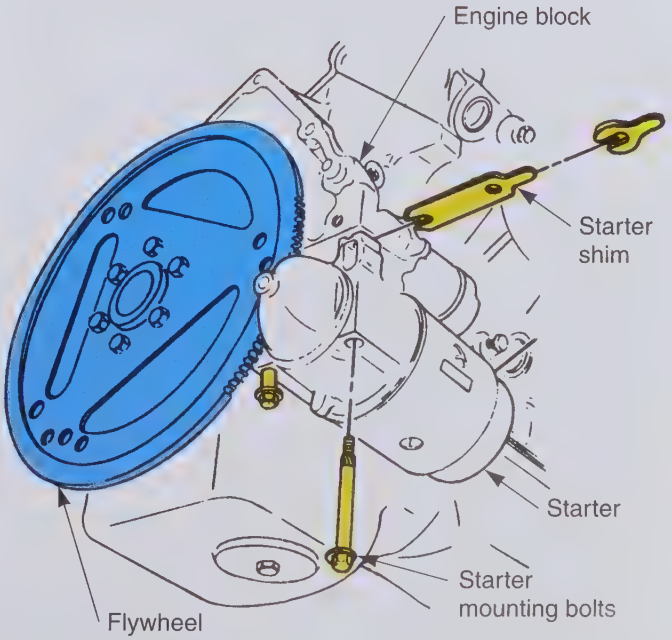

Figure 32-26. When installing the starter, replace any shims. Install wires without overtightening and stripping the terminal threads. Torque the mounting bolts or nuts to specifications. (GMC)

The apprentice technician uses a stethoscope to verify Duff's initial diagnosis. He places the stethoscope on the starter solenoid and is able to hear the solenoid closing when the key is turned to start. This tells him that current is reaching the solenoid from the ignition switch. The technician then checks the voltage drop across the solenoid terminals while the key is turned. The voltage drop is excessive, indicating a faulty solenoid.

Repair: The technician removes the starter and solenoid. He notices that a few teeth on the flywheel ring gear are worn but knows that this problem would not cause the starter to fail. After disassembling the starter, the technician finds that the large round contact inside the solenoid is burned, preventing current flow from the battery to the starting motor windings.

The technician calls Mr. Figueroa to get his approval before making the repairs. He explains that a faulty solenoid is causing the no-crank problem but warns Mr. Figueroa that a few teeth on the flywheel ring gear are worn down and may cause further cranking problems. Mr. Figueroa tells the technician to replace the starter and solenoid, but he does not okay flywheel ring gear replacement because of the added cost.

The technician installs a new starter and solenoid. He then starts the vehicle several times to make sure the problem has been fixed. As he prepares Mr. Figueroa's invoice, the technician notes that he warned the customer about the ring gear wear. He also notes that Mr. Figueroa chose not to have the repair done.

Summary

- In a no-crank problem, the engine crankshaft does not rotate properly with the ignition key at start. The most common causes are a dead battery, poor electrical connection, or faulty system component.
- A solenoid buzzing or clicking sound, without cranking, is commonly due to a discharged battery or poor battery cable connections.
- A starting system humming sound, after momentary engine cranking, may be due to a bad starter overrunning clutch or worn pinion gear unit.
- A starter metallic grinding noise may be caused by broken flywheel teeth or pinion gear teeth wear.
- A dead or discharged battery is one of the most common reasons the starting system fails to crank the engine properly.
- A starter current draw test measures the current used by the starting system. It will quickly tell you about the condition of the starting motor and other system parts.
- Voltage drop tests will quickly locate a part with higher than normal resistance.
- A starter ground circuit test checks the circuit between the starting motor ground and the negative battery terminal.
- A battery cable problem can produce symptoms similar to a dead battery, bad solenoid, or weak starting motor.
- A bad starter solenoid can cause a range of symptoms: click with no cranking, no cranking with no click, or slow cranking. It can also keep the engine or starting motor from shutting off.
- A starting motor rebuild typically involves removal and disassembly of starting motor; cleaning and inspection for part wear or damage; replacement of brushes, bushings, and any other worn or damaged parts; polishing or turning of commutator; lubrication, reassembly, testing, and installation of starting motor.
- Starter shims may be used to adjust the space between the pinion gear and the flywheel ring gear.
- Starter pinion gear clearance is the distance between the pinion and the drive end frame with the pinion engaged.

Important Terms

No-crank problem
Slow cranking condition
Starting headlight test
Starter current draw test
Voltage drop tests
Insulated circuit resistance test
Starter ground circuit test
Battery cable connection test
Starting motor rebuild
Starter shims
Growler
Starter pinion gear clearance

Review Questions—Chapter 32

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What are the most common causes of a no-crank problem?
2. A buzz or a click sound from the starter solenoid is normally due to a(n) _____ _____ or poor _____ _____ connections.
3. A humming sound, after momentary engine cranking, may be due to a bad _____ _____ or a bad _____ _____ unit.
4. What commonly causes a metallic grinding noise during starting?
5. Summarize how a starting headlight test is performed.
6. Why is a starter current draw test commonly used?
7. A high voltage drop in the starting system could indicate:
   (A) high resistance.
   (B) loose electrical connection.
   (C) corroded or burned terminal.
   (D) All of the above are correct.
8. How do you test the battery cables?
9. Explain some of the symptoms of a bad starter solenoid.
10. A bad ignition switch can keep the starting motor from working and can also make the engine crank all the time. True or False?
11. How do you adjust a neutral safety switch?
12. List the five major steps for a starting motor rebuild.
13. _____ _____ may be used to adjust the space between the pinion gear and the flywheel ring gear.
14. Define the term “growler.”
15. Always keep oil and grease away from the starting motor brushes and commutator. True or False?

ASE-Type Questions

1. A metallic grinding noise can be caused by each of the following *except:*
   (A) clashing gears.
   (B) broken flywheel teeth.
   (C) pinion gear tooth wear.
   (D) broken main feed wire.
2. After performing a starting headlight test, Technician A says the resulting bright lights and no-crank condition indicate starting circuit high resistance. Technician B says the test results suggest an open starting circuit. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Which of the following tests measures the number of amps used by a starting system?
   (A) Starter current draw test.
   (B) Starter ground circuit test.
   (C) Insulated circuit resistance test.
   (D) All of the above.
4. A battery cable problem produces symptoms similar to each of the following *except:*
   (A) bad solenoid.
   (B) dead battery.
   (C) weak starter motor.
   (D) brush holder problem.
5. Which of the following is not an indication of a bad starter solenoid?
   (A) Slow cranking.
   (B) Clicking without cranking.
   (C) Cranking without starting.
   (D) No cranking and no clicking.
6. When removing a starter motor, which of the following should be done first?
   (A) Disconnect the battery.
   (B) Mark the end frames.
   (C) Unbolt the battery cable.
   (D) Remove any solenoid fasteners.
7. Which of the following can be used to adjust the space between the pinion gear and the flywheel ring gear?
   (A) Ratchet.
   (B) Growler.
   (C) Starter shims.
   (D) Swivel wrench.

8. Which of the following is used to quickly check for armature shorts?
   - *(A) Growler.*
   - *(B) Ohmmeter.*
   - *(C) Tachometer.*
   - *(D) Starter shims.*
9. If an ohmmeter reads zero when testing a field coil, the windings:
   - *(A) are open.*
   - *(B) are not open.*
   - *(C) are shorted to the frame.*
   - *(D) are shorted to a starter component.*
10. With the pinion engaged, pinion gear clearance is the distance between the:
   - *(A) pinion and retainer.*
   - *(B) pinion and flywheel.*
   - *(C) pinion and drive end frame.*
   - *(D) pinion and commutator segments.*

Activities—Chapter 32

1. Demonstrate the use of a voltmeter in making voltage drop tests to detect excessive resistance in starting system components.
2. Make a videotape to show a procedure that would be hard to demonstrate for a class, such as starting motor removal and installation. Narrate the finished tape and play it for the class.

Starting System Diagnosis		
Condition	**Possible cause**	**Correction**
Starter fails to engage.	1. Battery discharged or faulty. 2. Faulty starting circuit wiring. 3. Defective starter relay. 4. Faulty starter solenoid. 5. Faulty starter. 6. Defective ignition switch. 7. Park/Neutral position switch faulty or misadjusted. 8. Clutch pedal position switch faulty or misadjusted.	1. Charge or replace battery. 2. Test and repair wiring. 3. Replace relay. 4. Replace solenoid or starter. 5. Replace starter. 6. Replace switch. 7. Replace or adjust switch. 8. Replace or adjust switch.
Starter engages but fails to turn engine.	1. Battery discharged or faulty. 2. Starting circuit wiring faulty. 3. Faulty starter. 4. Engine seized.	1. Charge or replace battery. 2. Test and repair wiring. 3. Replace starter assembly. 4. Repair engine.
Starter engages but spins out before engine starts.	1. Broken teeth on starter ring gear. 2. Faulty starter.	1. Replace ring gear. 2. Replace starter.
Starter fails to disengage.	1. Starter improperly installed. 2. Faulty starter relay. 3. Faulty ignition switch. 4. Faulty starter.	1. Install starter properly. 2. Replace relay. 3. Replace switch. 4. Replace starter.
Starter makes excessive noise.	1. Starter-to-flywheel housing mounting fasteners loose. 2. Dragging armature. 3. Dragging field pole shoes. 4. Dry bushings. 5. Chipped pinion teeth. 6. Chipped flywheel ring gear teeth. 7. Bent armature shaft. 8. Worn drive unit. 9. Loose starter through-bolts. Loose end frame bolts. 10. Flywheel ring gear misaligned.	1. Tighten mounting fasteners. 2. Replace armature and/or bushings. 3. Tighten pole shoes. 4. Lubricate bushings. 5. Replace pinion. 6. Replace ring gear. 7. Replace armature. 8. Replace starter drive unit. 9. Tighten all starter and frame cap bolts. 10. Install new ring gear.

33

Charging System Fundamentals

After studying this chapter, you will be able to:

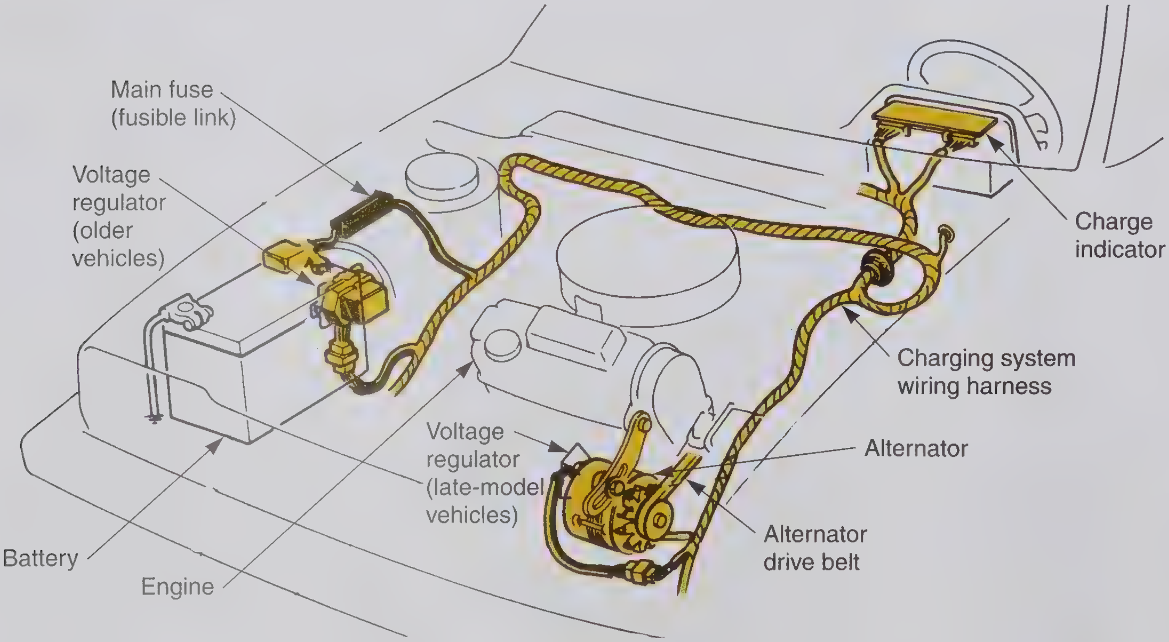
- List the basic parts of a charging system.
- Explain charging system operation.
- Describe the construction of major charging system components.
- Compare alternator and voltage regulator design differences.
- Explain charging system indicators.
- Describe safety practices to follow when working with charging systems.
- Correctly answer ASE certification test questions that require a knowledge of charging system fundamentals.

In the two previous chapters, you learned how the starting motor uses battery power to crank the engine. The starter consumed electricity and discharged the battery as the motor was drawing current.

In this chapter, you will learn how the charging system reenergizes the battery and supplies electricity for all the car's electrical systems. This chapter will give you a background in charging system terminology and prepare you for the next chapter on testing and repair.

Basic Charging System Parts

Figure 33-1 shows the major parts of a typical charging system. Study this illustration as each part is introduced.



Main fuse (fusible link)
Voltage regulator (older vehicles)
Charge indicator
Charging system wiring harness
Alternator
Voltage regulator (late-model vehicles)
Alternator drive belt
Battery
Engine

Figure 33-1. Review the names and locations of the basic parts of a charging system. (Honda)

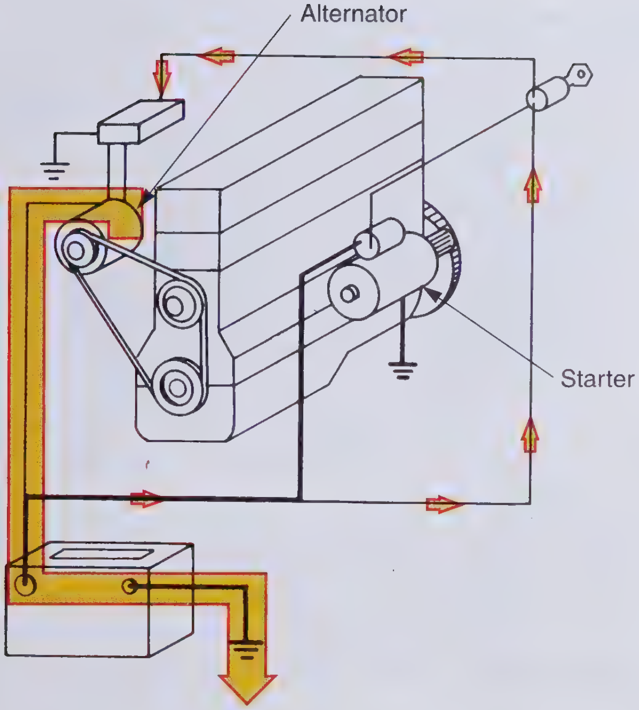


Figure 33-2. The charging system recharges the battery and supplies electricity when the engine is running.

- ***Alternator***—generator that uses mechanical (engine) power to produce electricity.
- ***Voltage regulator***—electronic device that controls the output voltage and current of the alternator. The engine control module may serve as the voltage regulator.
- ***Alternator drive belt***—links the engine crankshaft pulley with the alternator pulley to drive the alternator.
- ***Charge indicator***—ammeter, voltmeter, or warning light that informs the driver of the charging system condition.
- ***Charging system harness***—wiring that connects the parts of the system.
- ***Battery***—provides current to initially energize the alternator. Also helps to stabilize alternator output.

During engine cranking, the battery supplies all the electricity used by the automobile. Then, when the engine starts running, the charging system takes over to provide current to the vehicle's electrical systems.

The engine crankshaft pulley and alternator belt spin the alternator pulley. This powers the alternator and causes it to produce electricity, **Figure 33-2.**

The voltage regulator keeps alternator output at a preset *charging voltage* (13–15 volts). Since this is higher than battery voltage (12.6 volts), current flows back into the battery and recharges it. Current also flows to the ignition system, electronic fuel injection system, on-board computer, radio, or any other device using electricity.

Charging System Functions

The ***charging system*** performs several functions:

- It recharges the battery after engine cranking or after the use of electrical accessories with the engine shut off.
- It supplies all the vehicle's electricity when the engine is running.
- It provides a voltage output that is slightly higher than battery voltage.
- It changes output to meet different electrical loads.

Types of Charging Systems

There are two basic charging systems: alternator (ac generator) systems and dc generator systems. Alternator charging systems have replaced the older dc generator systems. Keep in mind, however, that an alternator is sometimes called a generator, meaning ac generator. **Figure 33-3** shows the fundamental differences between an alternator and a dc generator.

DC Generator

A ***dc generator*** is similar to an electric motor. It has a stationary magnetic field. The output conductor unit (armature) spins inside this field. This induces current output from within the armature.

The dc generator was fine for producing electricity on early model cars. However, today's cars have more electrical components requiring high-current output. A dc generator would not be able to supply enough current for a modern car at idle speeds. The efficiency of dc generators is poor at low engine speeds.

AC Generator (Alternator)

An ***alternator,*** or ***ac generator,*** has replaced the dc generator because of its improved efficiency. It is smaller, lighter, and more dependable than a dc generator. The alternator will also produce more output at idle than a dc generator. This makes it ideal for use in late-model cars.

The alternator has a spinning magnetic field, as illustrated in **Figure 33-3.** The output conductors (windings) are stationary. As the field rotates, it induces current in the output windings. In a way, alternator construction is the reverse of dc generator construction.

Alternator Operation

The two main parts of a simplified alternator are the rotor and stator, **Figure 33-4.** The alternator rotor is located in the center of the alternator housing. It creates a rotating magnetic field. The alternator drive belt turns the rotor, making the field rotate.

The alternator stator is a stationary set of windings. The stator surrounds the rotor. It is the output winding in the alternator.

When the rotor spins, its strong magnetic field cuts across the stator windings. This induces current in the stator windings. If the stator windings are connected to a load (a lightbulb, for example), the load would operate (glow).

AC Output

Alternating current (ac) flows one way and then the other. The simple alternator in **Figure 33-4** produces an ac output. As the rotor turns into one stator winding, current is induced in one direction. Then, when the same rotor pole moves into the other stator winding, current reverses and flows out in the other direction.

Rectified AC Current

An automobile electrical system is designed to use direct current (dc), which flows in only one direction. It cannot use the alternating current as it comes out of the alternator's stator. Therefore, the alternator current must be ***rectified*** (changed) into direct current before entering the vehicle's electrical system.

A ***diode*** (covered in Chapter 8) is an electronic device that allows current flow in only one direction. It serves as an "electrical check valve." Look at **Figure 33-5.**

When a diode is connected to a voltage source in such a way that current passes through the diode, the diode is said to be ***forward biased.*** A forward-biased diode acts as a conductor.

When ***reverse biased,*** the diode is connected to a voltage source in such a way that current does not pass through. A reverse-biased diode acts like an insulator.

If a diode were placed on the stator output of our simple alternator, current would only flow out through

Generator **Alternator**

Figure 33-3. Comparison of an old dc generator and modern ac generator, or alternator. Note how fields and windings are in opposite locations. (Ford and Bosch)

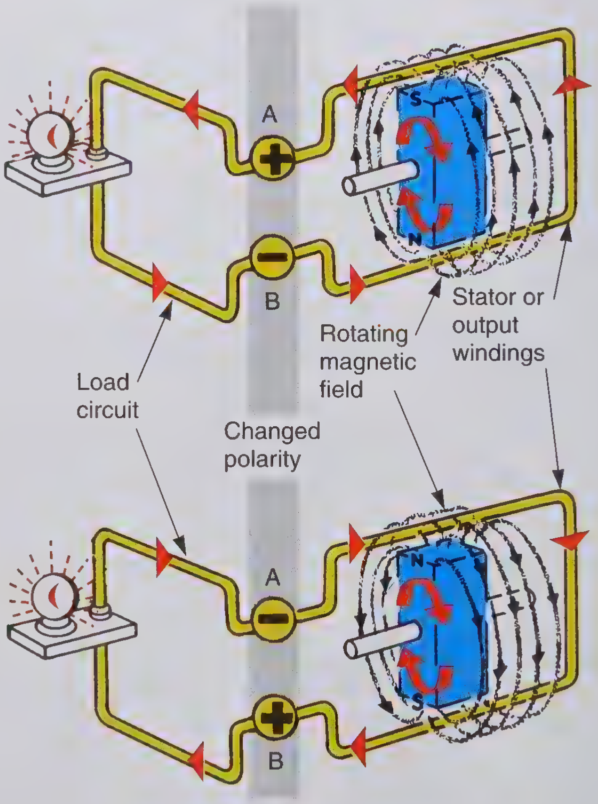

Figure 33-4. Basic alternator operation. A rotating magnetic field moves across the stationary windings. Current is induced in the windings and out to the load. When the rotating field turns one-half turn, the polarity of the windings is reversed. This causes current to flow out to the load in the opposite direction. Alternating current is produced. (Deere & Co.)

the circuit in one direction. This is illustrated in **Figure 33-6.** Study diode action.

A single diode would not use all the alternator's output, however. Also, it would result in pulsing direct current, not smooth current flow. Therefore, an alternator uses several diodes connected into a rectifier circuit. This produces more efficient alternator output.

Alternator Construction

It is very important that you understand alternator construction. This information is essential if your are to properly test and repair alternators.

Pictured in **Figure 33-7,** the main components of a typical alternator are:

- ***Rotor assembly***—field windings, claw poles, rotor shaft, and slip rings.
- ***Brush assembly***—brush housing, brushes, brush springs, and brush wires.
- ***Rectifier assembly***—diodes, heat sink or diode plate, and electrical terminals.
- ***Stator assembly***—three stator windings or coils, stator core, and output wires.
- ***Housing***—drive end frame, slip ring end frame, and end frame bolts.
- ***Fan and pulley assembly***—fan, spacer, pulley, lock washer, and pulley nut.
- ***Voltage regulator***—an electronic voltage regulator may be mounted in or on a modern alternator. In some cases, the engine control module serves as the voltage regulator.

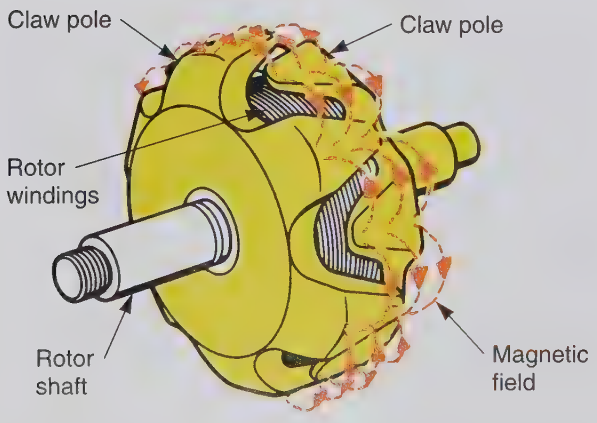
Figure 33-7. This exploded view shows the major parts of an alternator. Study the names of the parts and the general construction. (Ford)

Alternator Rotor

An ***alternator rotor*** consists of field coil windings mounted on a shaft. Two claw-shaped pole pieces surround the field windings to increase magnetic field strength. This is illustrated in **Figure 33-8.**

The fingers on one of the pole pieces produce S (south) poles. The fingers on the other pole piece form N (north) poles. As the rotor spins inside the alternator, the alternating polarity (North-South-North-South) produces an alternating current.



Claw pole
Claw pole
Rotor windings
Rotor shaft
Magnetic field

Figure 33-8. The rotor consists of windings surrounded by claw-shaped poles. The poles strengthen the magnetic field around the windings. The shaft supports the poles and windings. (Bosch)

Alternator Slip Rings

Alternator slip rings are mounted on the rotor shaft to provide current to the rotor windings. Each end of the field coil connects to one of the slip rings. An external source of electricity is needed to excite the field. See **Figure 33-9.**

Alternator Bearings

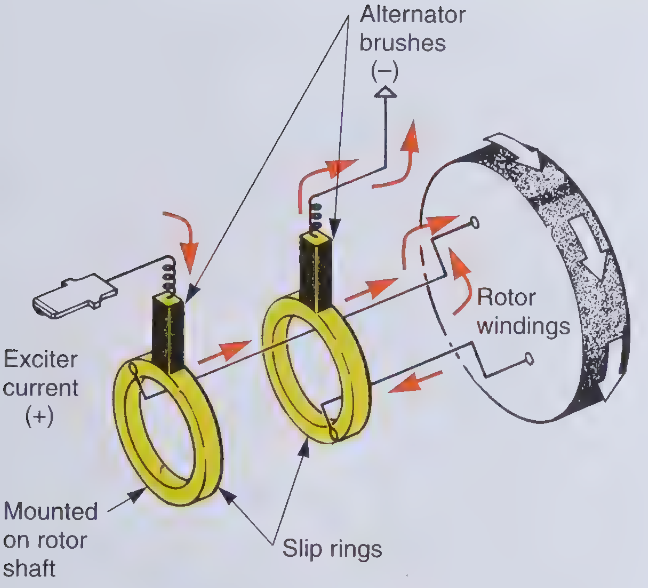
Alternator bearings (needle or ball types) are commonly used to produce a low-friction surface for the rotor shaft. These bearings support the rotor and shaft as they spin inside the stator.

The alternator bearings are normally packed with grease. The front bearing is frequently held in place with a small plate and screws. The rear bearing is usually press-fit into place.

Alternator Brushes

Alternator brushes ride on the slip rings to make a sliding electrical connection. The brushes feed battery current into the slip rings and rotor windings.

Small ***brush springs*** hold the brushes in contact with the slip rings. Current flow into the rotor windings is low.



Alternator brushes
(–)
Rotor windings
Exciter current
(+)
Mounted on rotor shaft
Slip rings

Figure 33-9. Brushes and slip rings allow current to be fed into rotor windings. This excites windings to produce a rotating magnetic field. (Motorola)

Therefore, the brushes are small compared to motor brushes. Look at **Figure 33-9** again.

Alternator Rectifier

An ***alternator rectifier*** assembly, also called a ***diode assembly,*** commonly uses six diodes to convert stator output (alternating current) to direct current. The diodes are usually wired as shown in **Figure 33-10.** The rectifier provides ***full-wave rectification*** (changes both positive and negative outputs into direct current) as the different polarity rotor claws pass the stator windings.

A ***diode trio*** may be used to supply current to the rotor field windings. In a diode trio, three diodes are connected to the field through a connection in the voltage regulator. The stator output feeds the diode trio. **Figure 33-11** shows how the rectifier assembly is connected to the stator assembly.

The ***rectifier diodes*** are mounted in a ***diode frame*** or ***heat sink*** (metal mount for removing excess heat from electronic parts). Three positive diodes are press-fit in an insulated frame, and three negative diodes are mounted in an uninsulated or grounded frame.

Alternator Stator

The ***alternator stator*** consists of three groups of windings. The windings are wrapped around a soft,

laminated iron core or ring. A stator with an attached rectifier is shown in **Figure 33-12.**

The stator produces the electrical output of the alternator. As you can see, the stator windings connect to the diode assembly. The iron core is used to concentrate and strengthen the field around the stator windings.

Figure 33-12. The rectifier assembly consists of six diodes in heat sink. Wires from the stator windings connect to the rectifier. An iron core around the stator windings increases induction. (Mercury)

A ***Y-type stator*** has the wire ends from the stator windings connected to a neutral junction. The circuit looks like the letter "Y," as shown in **Figure 33-10.** A Y-type stator provides good current output at low engine speeds.

A ***delta-type stator*** has the stator wires connected end to end. This is shown in **Figure 33-10.** With no neutral junction, two circuit paths are formed between the diodes during each phase. A delta-type stator is used in high-output alternators.

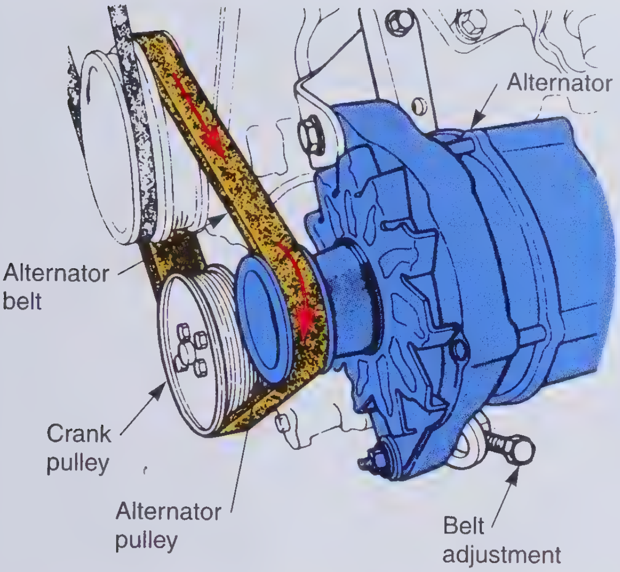
Alternator Fan

To provide cooling for the alternator, an ***alternator fan*** is mounted on the front of the rotor shaft. Normally, the fan is located between the pulley and the front bearing. Look at **Figure 33-13.**

As the rotor and shaft spin, the whirling alternator fan helps draw air through and over the alternator. This cools the windings and diodes to prevent overheating and damage.

Alternator Pulley and Belt

An ***alternator pulley*** provides a means of spinning the rotor through the use of a belt. The pulley is secured to the front of the rotor shaft by a large nut. See **Figure 33-14.**



Alternator
Alternator belt
Crank pulley
Alternator pulley

Figure 33-14. The crankshaft pulley turns the alternator belt. The belt powers the alternator. This is a ribbed belt. (Sun Electric)

An ***alternator belt,*** powered by the crankshaft pulley, turns the alternator pulley and rotor. One of three belt types may be used: V-belt, cogged V-belt, and ribbed belt. These are pictured in **Figure 33-15.** Covered in other chapters, these types of belts are also used to drive the power steering pump, air-conditioning compressor, water pump, and other units.

C

Figure 33-15. Three types of belts. A—Conventional V-belt. B—Clogged V-belt. C—Ribbed belt. (Ford)

Voltage Regulator

A ***voltage regulator*** controls alternator output by changing the amount of current flowing through the rotor windings. Any change in rotor winding current changes the field strength acting on the stator (output) windings. In this way, the voltage regulator can maintain a preset charging voltage.

Figure 33-16 shows a common location for a voltage regulator and its terminals. In many cases, the engine control module serves as the voltage regulator. However,

Regulator mounting location
Electronic, integrated circuit (IC) regulator
Remotely mounted electronic or transistorized regulator
Contact point or electromechanical regulator

Figure 33-17. The three basic voltage regulators. (DaimlerChrysler)

if the vehicle is equipped with a conventional regulator, it is one of three basic types:

- Electronic regulator mounted inside or on the back of the alternator (integral voltage regulator).
- Electronic regulator mounted away from alternator in engine compartment.
- Contact-point regulator mounted away from alternator in engine compartment. See **Figure 33-17.**

Electronic Voltage Regulators

An ***electronic voltage regulator*** uses an electronic circuit (transistors, diodes, resistors, and capacitors) to control rotor field strength and alternator output, **Figure 33-18.**

An electronic voltage regulator is a sealed unit and cannot be repaired. The electronic circuit must be sealed because it can be damaged by moisture, excessive heat, and vibration. Usually the circuit is surrounded by a rubber-like gel for protection.

An ***integral voltage regulator*** is an electronic regulator comprised of integrated circuits and mounted inside or on the rear of the alternator. It is the most common type used on today's vehicles. The integral regulator is small, efficient, and dependable.

Electronic Voltage Regulator Operation

To increase alternator output, the electronic voltage regulator allows more current into the rotor windings. This strengthens the magnetic field around the rotor. More current is then induced in the stator windings, increasing alternator output. Look at **Figure 33-18.**

To reduce alternator output, the electronic regulator places more resistance between the battery and the rotor windings. Field strength drops and less current is induced in the stator windings.

Alternator speed and electrical load determine whether the regulator increases or decreases charging output. If the load is high or the rotor speed is low (engine idling), the regulator will sense a drop in system voltage. The regulator then increases rotor field current until a preset output voltage is obtained. If the load drops or rotor speed increases, the opposite occurs.

Battery Thermistor

In some systems, a ***battery thermistor*** is used to measure battery temperature so the charging system can alter charging output as needed. Generally, a cold battery requires more voltage for recharging than a hot battery. The battery thermistor is often mounted on the positive battery cable. It rests against the battery so it can measure battery temperature.

Computer Monitoring and Control

The ***engine control module*** or the ***powertrain control module*** is sometimes used to supplement or replace the conventional voltage regulator to more precisely control the charging circuit.

With computer monitoring, the control module is wired into the charging system circuit as shown in **Figure 33-19.** When the ignition key is turned on, power is fed to the alternator and regulator from the module.

The control module can monitor charging system output and react to changing operating conditions. For example, the module can shut the alternator off at wide-open throttle for better vehicle acceleration, saving several horsepower. It can more accurately control charge rate, allowing the use of a smaller, lighter battery. The module can also monitor system operation to simplify diagnosis and repair by producing trouble codes and problem descriptions.

Figure 33-20. Note how this charging system does not have a voltage regulator inside or on alternator. Instead, a regulator circuit is included in the power train control module. This allows more precise control of the charging voltage for improved vehicle efficiency. Also note how meters can be connected for testing the current output of system. (DaimlerChrysler)

Voltage regulator switching is very fast (about 400 cycles per second) to help prevent radio noise. At low engine and alternator speeds and with a high load, the regulator may use a 90% on-time to produce an output to meet the high load.

Modern electronic voltage regulators, either integral or in-computer types, can also progressively switch on charging voltage. If the full load of the alternator were to come on instantly, it could lug the idling engine down.

A modern charging system that does not use a conventional regulator is shown in **Figure 33-20**. In this system, a ***computer voltage regulator circuit*** is located inside the power train control module, or computer. The computer voltage regulator circuit provides better control of the charging system. For example, the computer voltage regulator circuit can shut off the alternator at wide-open throttle to reduce power loss for improved acceleration.

Fail-safe Circuit

Some late-model charging systems have ***fail-safe circuits,*** which disconnect alternator output if voltage levels become too high. This protects all the on-board electronics from being damaged by high voltage. The fail-safe circuit is designed into the voltage regulator.

Contact-Point Voltage Regulator

Contact-point voltage regulators use a coil, a set of points, and resistors to control alternator output. This is an older type of regulator that has been replaced by electronic or solid-state units.

Charge Indicators

A ***charge indicator*** informs the driver of the operating condition or output of the charging system. There are three basic types of charge indicators:

- ***Warning light***—glows if alternator output is below a specified level.
- ***Voltmeter indicator***—measures voltage output of alternator.
- ***Ammeter indicator***—measures current output of alternator.

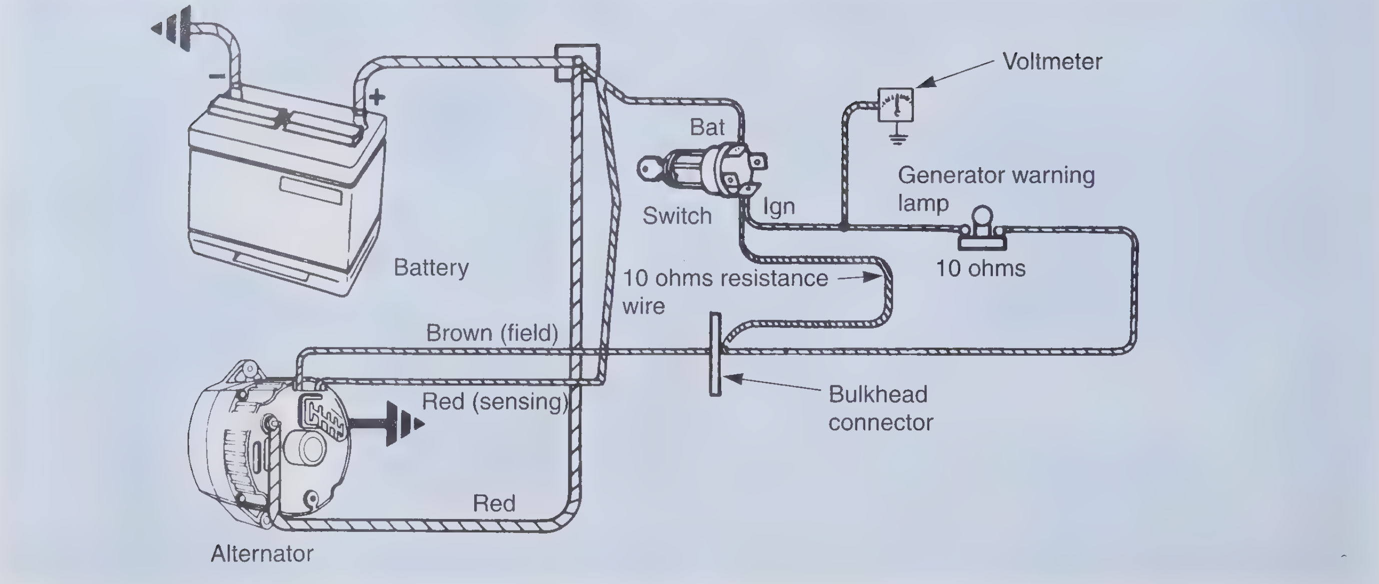

Figure 33-21. The charging circuit shows connections for a generator warning lamp and voltmeter. (General Motors)

These indicators are mounted in the dash of the car. Normally, all cars have an indicator light. A voltmeter or ammeter may be added for more precise monitoring of charging system action.

Alternator Warning Light

An ***alternator warning light*** is wired into the charging system so that it will glow when alternator output drops to a specified level. **Figure 33-21** shows one circuit using an alternator warning light.

If problems develop in the charging system, the field current, trying to increase alternator output, will increase enough to light the indicator bulb. If the charging system is in good operating condition, current flow through the field will be too low to light the bulb.

Voltmeter Indicator

A ***voltmeter indicator*** can also be used to warn the driver of charging system problems. Refer to **Figure 33-21.** The voltmeter reads the system voltage when the engine is running.

A battery has 12.6 volts when fully charged. To recharge the battery, alternator output must be higher than the battery voltage. Alternator output is normally 13–15 volts.

The voltmeter indicator simply shows voltage, which is an indicator of current output and charging system condition. If the voltmeter reading drops to battery voltage or below, the charging system has problems. If the voltmeter reading is too high, overcharging can occur. ***Overcharging*** results when excess current is forced through the battery. Battery overheating damage can result after extended overcharging. This problem is often due to a faulty voltage regulator.

Ammeter Indicator

An ***ammeter indicator*** simply shows the current output of the alternator in amps. A simplified circuit containing an ammeter is shown in **Figure 33-22.** Study it carefully.

Basically, if the ammeter reads to the right side of the scale (positive dial mark), the battery is being charged. If the ammeter reads to the left side of the scale (negative dial mark), the charging system is not working properly.

Industry Trend

As the number of electrical components (computers, electrical accessories, etc.) in modern vehicles has increased, the demand on the standard 12-volt electrical system has grown dramatically. Manufacturers project that in the near future, the electrical demand of a typical vehicle will exceed the capability of the standard 12-volt system. Therefore, automakers are currently working to adopt a 42-volt electrical system, which will meet the electrical demands of the automobile for years to come.

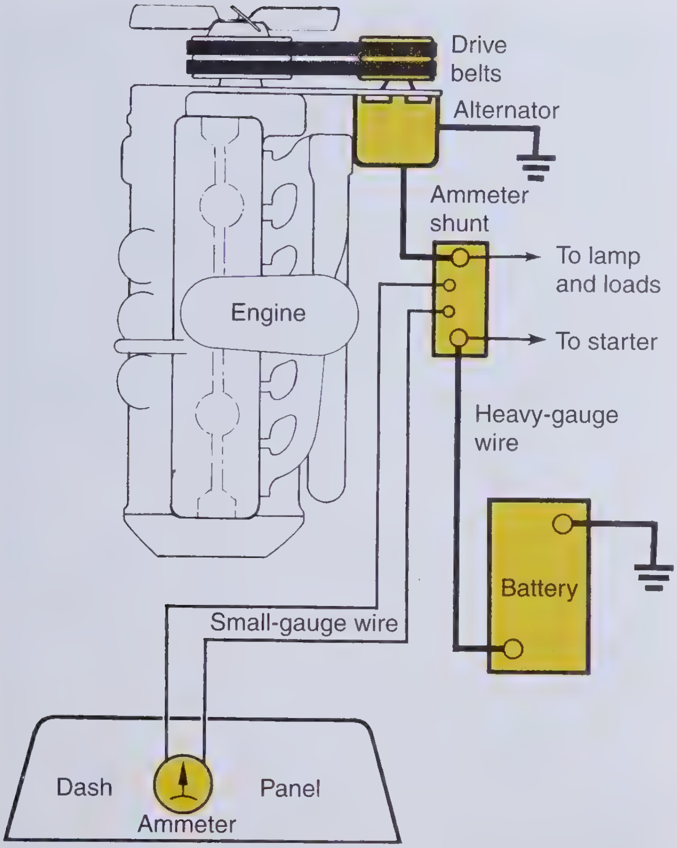

Figure 33-22. Circuit showing basic connections for ammeter indicator. (Motorola)

Summary

- An alternator is a generator that uses mechanical (engine) power to produce electricity.
- The voltage regulator controls the alternator output voltage and current.
- The alternator belt links the engine crankshaft pulley with alternator pulley to drive the alternator.
- A charge indicator can be an ammeter, voltmeter, or warning light. Indicators inform the driver of charging system condition.
- The battery provides current to initially energize alternator and also helps stabilize alternator output.
- The voltage regulator keeps alternator output at a preset charging voltage (13–15 volts).
- The alternator rotor is a rotating magnetic field. It fits in the center of the alternator housing. The alternator drive belt turns the rotor, making the field spin.
- The alternator stator is a stationary set of windings. Alternator current must be rectified (changed) into direct current before entering the electrical system.

Important Terms

Alternator

Ammeter indicator

Review Questions—Chapter 33

Please do not write in this text. Place your answers on a separate sheet of paper.

1. List and explain the six major parts of a charging system.
2. The voltage regulator keeps alternator output at a preset charging voltage of approximately _____ to _____ volts.
3. What are four functions of a charging system?
4. The dc generator is the most common type of automotive charging system. True or False?
5. The alternator will produce more output at idle than the dc generator. True or False?
6. The alternator is a device for changing mechanical energy into _____ energy.
7. Explain the alternator's rotor and stator.
8. Define the term "rectified current."

9. This alternator device can be used to change alternating current into direct current.
   (A) Transistor.
   (B) Capacitor.
   (C) Stator.
   (D) Diode.
10. What do the terms forward and reverse bias mean?
11. List and explain the seven major parts of an alternator.
12. An alternator _____ consists of field coil windings mounted on a shaft.
13. Alternator brushes ride on _____ _____ to feed current to the rotor windings.
14. An alternator rectifier assembly provides full-wave rectification. True or False?
15. An alternator _____ consists of three groups of windings or coils that surround the spinning rotor.
16. A voltage regulator controls alternator output by changing the amount of current flowing through the _____ _____.
17. Which of the following is *not* a typical type of voltage regulator?
   (A) Contact point type mounted away from alternator.
   (B) Electronic type mounted away from the alternator.
   (C) Integral electronic type.
   (D) Integral contact point type.
18. A(n) _____ voltage regulator is an electronic unit mounted inside or on rear of alternator.
19. Alternator ______ and electrical _____ determine whether the regulator increases or decreases charging output.
20. List and explain three types of charging system indicators.

ASE-Type Questions

1. A charge indicator can be any of these *except* a(n):
   (A) ammeter.
   (B) voltmeter.
   (C) ohmmeter.
   (D) warning light.
2. Technician A believes that once an engine starts running, the engine crankshaft pulley powers the alternator to supply electricity to a car's electrical systems. Technician B feels a battery is a car's sole electrical supplier. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Charging voltage is approximately:
   (A) 12.6 volts.
   (B) 13–15 volts.
   (C) 16–19 volts.
   (D) 20–25 volts.
4. Which of the following is *not* a type of basic charging system?
   (A) Alternator.
   (B) AC generator.
   (C) DC generator.
   (D) Stationary diode.
5. The component that is turned by the alternator drive belt and creates a rotating magnetic field is the:
   (A) rotor.
   (B) stator.
   (C) rectifier.
   (D) diode trio.
6. Each of these is a rectifier assembly component *except:*
   (A) diodes.
   (B) heat sink.
   (C) stator.
   (D) electrical terminals.
7. Which device has stator wires connected end to end?
   (A) Y-type stator.
   (B) Delta-type stator.
   (C) Voltage regulator.
   (D) Stator neutral lead.
8. Which of the following is *not* a type of alternator belt?
   (A) V.
   (B) Ribbed.
   (C) Cogged V.
   (D) Integrated.

9. Electronic voltage regulators use these to control rotor field strength and alternator output.
    - *(A) Diodes.*
    - *(B) Capacitors.*
    - *(C) Transistors.*
    - *(D) All of the above.*
10. When fully charged, an automotive battery has:
    - *(A) 12.6 volts.*
    - *(B) 13–15 volts.*
    - *(C) 16–19 volts.*
    - *(D) 20–25 volts.*

Activities—Chapter 33

1. Vehicles from different manufacturers use various belt arrangements to drive the alternator. Identify at least three different belt arrangements and sketch them. Label each sketch with vehicle make and engine type.
2. A diode is sometimes called "an electrical check valve." Make sketches to show why it received that name.

34 Charging System Diagnosis, Testing, and Repair

After studying this chapter, you will be able to:

- Diagnose charging system troubles.
- Inspect a charging system.
- Test charging system output with a voltmeter or a load tester.
- Remove, test, repair, and replace an alternator.
- Adjust an alternator belt.
- Remove and replace a voltage regulator.
- Describe safety practices to follow when testing or repairing a charging system.
- Correctly answer ASE certification test questions on charging system diagnosis and repair.

This chapter begins by summarizing the types of troubles that occur in a modern charging system. You will learn how to perform fundamental tests that help locate problems. Then, the chapter covers parts removal, disassembly, repair, and reassembly. This should give you a sound background in the most common types of charging system service and repair jobs.

Charging System Diagnosis

Although a charging system has only two major parts (alternator and regulator), troubleshooting can be difficult. Sometimes, another system's fault (bad starting motor, defective battery, computer failure, or faulty wiring) will appear to be caused by problems in the charging system.

There are four common symptoms of charging system problems:

- Dead battery—slow or no cranking.
- Overcharged battery—water must be added frequently, or the battery suffers overheating damage.
- Abnormal noises—grinding, squealing, and buzzing.
- Indicator shows problem—light glows all the time or there is an incorrect indicator reading.

Verify these problems by starting or trying to start the engine. It is possible that the symptoms have been misinterpreted by the service writer or customer. For example, a problem described as a no-charge condition may really be a shorted starting motor, battery drain, or other trouble.

Warning!
Some late-model cars are equipped with a heated windshield. When the windshield is being heated, the alternator produces 110 volts ac. This is enough voltage to cause electrocution. Keep this in mind when working on this type system.

Visual Inspection

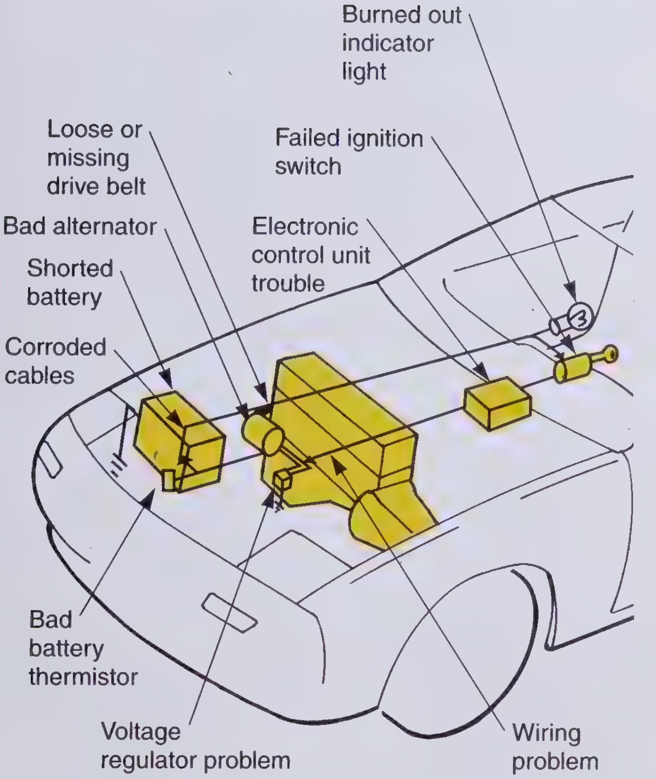
Open the hood and visually inspect the parts of the charging system. Check for obvious troubles, like the ones given in **Figure 34-1.**

Check for battery problems, such as loose battery cables, a discharged battery, corroded terminals, a low water level, or a damaged battery case.

Check for alternator belt problems. Make sure the belt is adjusted properly. A loose alternator drive belt may squeal or flap and prevent normal charging, **Figure 34-2.** Also, check the condition of the belt. Look for cracks, glazing (hard, shiny surface), grease or oil contamination, and deterioration. These conditions are shown in **Figure 34-3.**

If needed, alternator belt tension can be adjusted as follows:

1. Loosen the alternator mounting and adjusting bolts.
2. Pry on a strong surface of the end frame. Pull hard enough to produce proper belt tension. Refer to **Figure 34-4.**

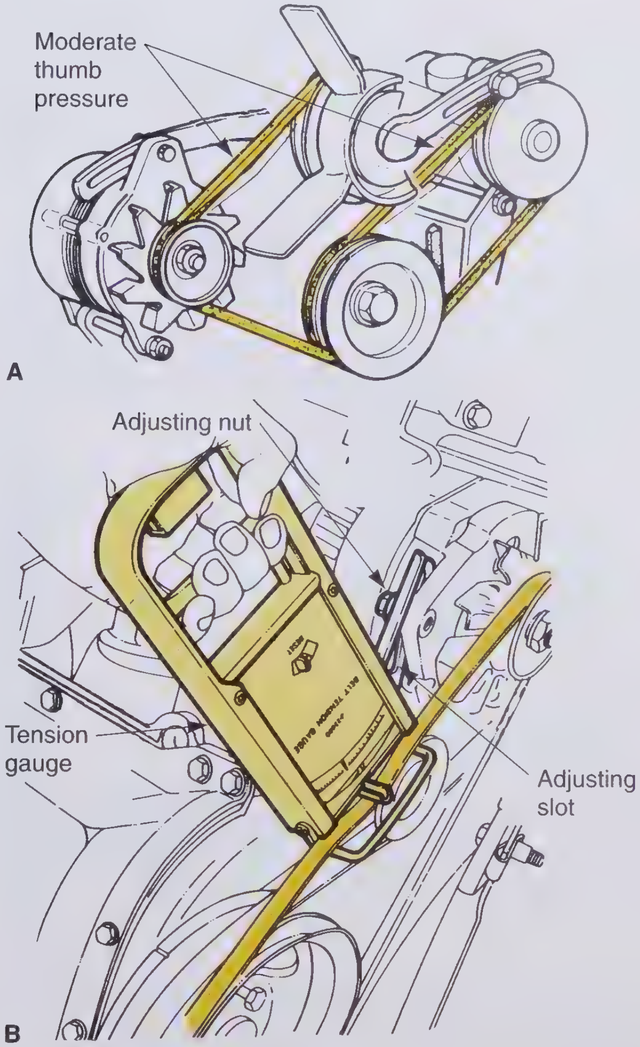


Burned out indicator light
Loose or missing drive belt
Failed ignition switch
Bad alternator
Electronic control unit trouble
Shorted battery
Corroded cables
Bad battery thermistor
Voltage regulator problem
Wiring problem

Figure 34-1. Note common problems in a charging system. Some of these could be found during inspection.

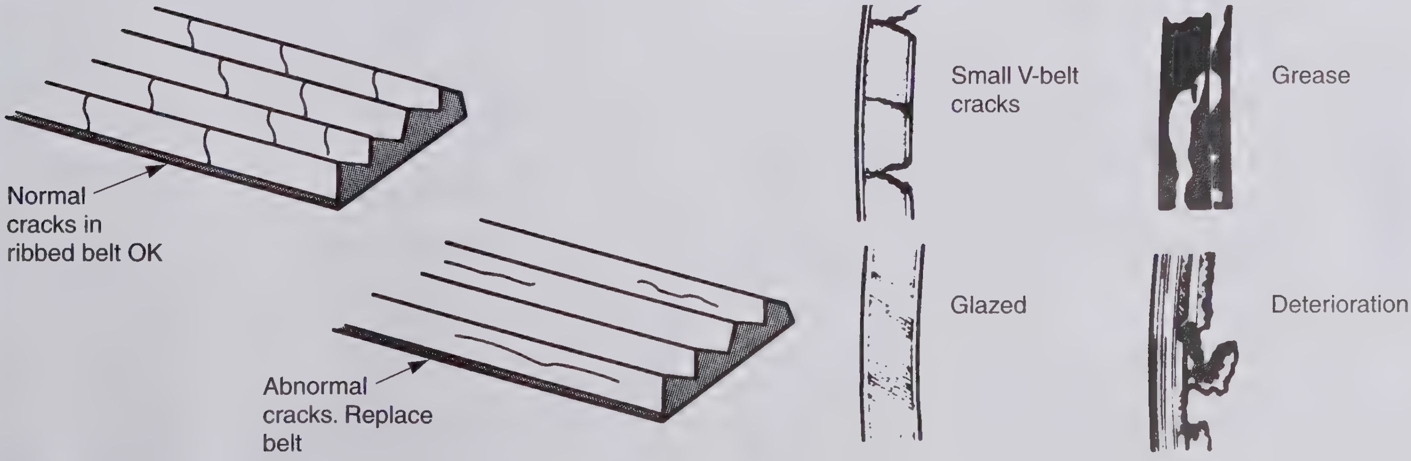
3. Tighten the adjusting bolt while holding the pry bar.
4. Tighten any other mounting bolts.
5. Recheck tension.

Caution!
Tighten an alternator belt only enough to prevent belt slippage or flap. Overtightening is a common mistake that quickly ruins alternator bearings.



Moderate thumb pressure
A
Adjusting nut
Tension gauge
Adjusting slot
B

Figure 34-2. A loose alternator belt can cause low charging system output and a dead battery. The belt should deflect 1/2″ when pressed with your thumb. A belt tension gauge provides a slower but more accurate way of checking tension. (Mazda and DaimlerChrysler)



Normal cracks in ribbed belt OK
Abnormal cracks. Replace belt
Small V-belt cracks
Grease
Glazed
Deterioration

Figure 34-3. Inspect belts closely for these kinds of problems. Replace belt if needed. (Snap-On Tools and DaimlerChrysler)

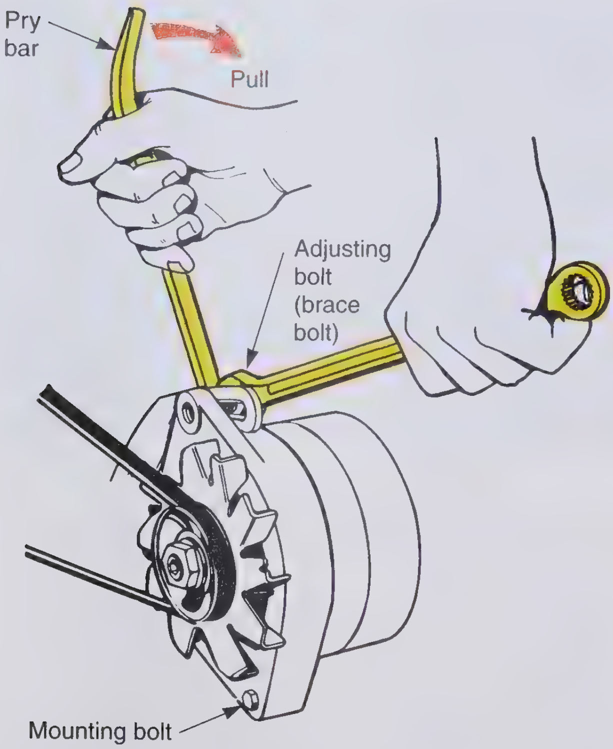


Figure 34-4. To adjust belt, loosen mounting and adjusting bolts. Pry on the thick area of end frame. Hold tension while tightening adjustment bolt. Check tension and tighten any other bolts. (Florida Dept. of Voc. Ed.)

Check for wiring problems in the charging system, **Figure 34-1.** Check for loose or corroded electrical connections, shorted wires (missing insulation), and other problems.

In particular, check the connections on the back of the alternator, on the regulator (type mounted away from alternator), and on the engine control module (computer-controlled voltage regulation). Wiggle the wires while the engine is running. If the indicator light goes out or the indicator gauge begins to read properly when a wire is moved, the problem is in that area of the wiring.

Tech Tip!
Connect a voltmeter across the battery terminals while wiggling charging system wires. If the meter fluctuates to a higher voltage when a wire is wiggled, you have found the bad electrical connection. Otherwise, you would need a helper to watch the charge indicator light on the instrument panel.

Listen closely for abnormal noises in the alternator. If necessary, use a stethoscope to listen to the alternator. Try to detect internal grinding (worn, dry bearings), whining (leaking diodes or overcharging), or any other unusual sounds.

Scanning Charging System

On most vehicles with self-diagnostic systems, you can connect a scan tool to the vehicle to aid in troubleshooting. The scan tool will display charging voltage, battery temperature, and other data useful in finding problems. Capabilities vary with each model; refer to the service manual or scanner instructions for details.

Charging System Precautions

Observe the following rules when working on a charging system. They will help prevent possible damage to electrical-electronic systems.

- *Disconnect the battery before removing any charging system component.* If a ***hot wire*** (current-carrying wire) touches ground, parts could be ruined. Disconnect the battery before connecting it to a battery charger. A voltage surge or high voltage can damage electronic components in the alternator, regulator, and other computerized systems.
- *Never reverse polarity.* If the battery or jumper cables are connected backwards, serious electrical damage can occur. Reversing polarity can damage the diodes in the alternator, ruin the circuit in the regulator, and burn electronic components in other computer systems.
- *Do not operate the alternator with the output wire disconnected.* If the alternator is operated with the output wire disconnected, alternator voltage can increase above normal levels. Alternator or charging circuit damage could result.
- *Never short or ground any charging system terminal unless instructed to do so by a shop manual.* Some circuits can be grounded or shorted without damage; others will be seriously damaged. Refer to a service manual when in doubt.
- *Do not attempt to polarize an alternator.* DC generator systems had to be polarized (voltage connected to generator field) after repairs. This must *not* be done with an alternator.

Charging System Tests

Charging system tests should be done when symptoms point to low alternator voltage and current. These tests will quickly determine the operating condition of the charging system. There are five common charging system tests:

- Charging system output test—measures current and voltage output of the charging system under a load.

- Regulator voltage test—measures charging system voltage under low-output, low-load conditions.
- Regulator bypass test—connects full battery voltage to the alternator field.
- Scope testing—analyzes voltage waveform.
- Circuit resistance tests—measures resistance in insulated and ground circuits of the system.

Charging system tests are performed in three ways: using a load tester (same tester used to check the battery and starting system in earlier chapters), a scope tool, or a common VOM (volt-ohm-milliammeter).

A ***load tester*** provides the most accurate method of checking a charging system. See **Figure 34-5.** It will measure both system current and voltage while applying a load to the system.

Before testing the charging system, it is common practice to check the condition of the battery. Although charging system problems often show up as a dead battery, you must not forget that the battery itself may be bad. Measure the battery's state-of-charge and perform a battery load test (see Chapter 30). Then, you will be sure that the battery is not affecting your charging system tests.

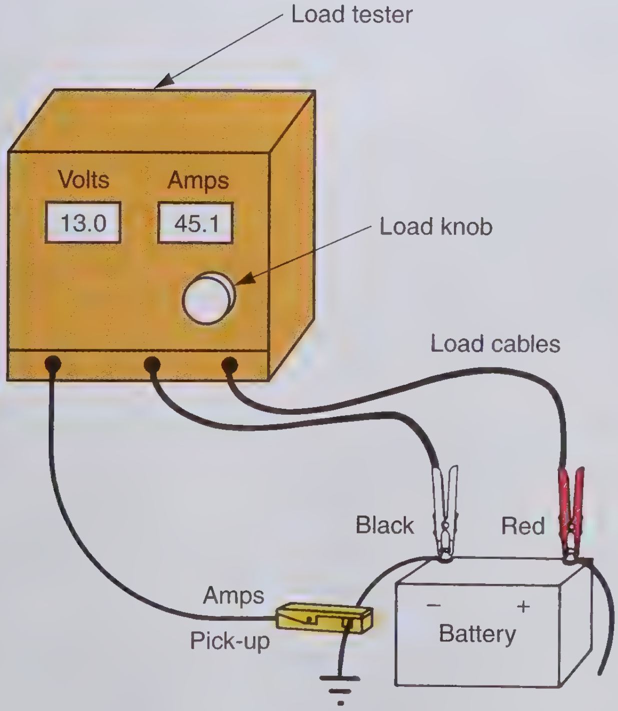

Figure 34-5. Load testers, as used during battery and starting system tests, will also check charging output. Modern testers have an inductive, clip-on current clamp. Older testers must have an ammeter connected in series. (Marquette)

Charging System Output Test

A ***charging system output test*** measures system current and voltage under maximum load (current output). To check charging system output with a load tester, connect the tester leads as described by the manufacturer.

With modern testers, two leads fasten to the battery terminals. The inductive (clip-on) amps pickup fits around the insulation on the negative battery cable. See **Figure 34-5.** Procedures differ with older, noninductive testers. Check the tester's operating instructions when in doubt.

A charging system output test is performed as follows:

1. Set the load tester controls to their proper positions.
2. Start the engine and adjust the engine idle speed to the test specifications.
3. Rotate the load control on the tester until the ammeter displays the maximum current output. Do not exceed the alternator's output rating. Do not let the voltage drop below specifications (about 12 volts).
4. Turn off the load control and evaluate the readings.

Charging System Output Test Results

Compare the results of your charging system output test to the alternator's output specifications. If the test results are not within specifications, further testing will be needed.

Tech Tip!
Alternator current specifications are sometimes stamped on the alternator housing. If not, look up the alternator specifications in the service manual.

Current output specifications for charging systems depend on the size (rating) of the alternator. For instance, a car with few electrical accessories may have an alternator rated as low as 35 amps. A luxury car with many accessories (air conditioning, speed control, power windows, etc.) might have an alternator with a much higher rating (40–80 amps). Always look up exact factory values when evaluating charging system operation.

If the charging system output current is low, perform regulator voltage and regulator bypass tests. They will let you determine whether the alternator, regulator, or circuit wiring is at fault. Even if the output test is within 10% of specifications, perform a regulator voltage test.

Regulator Voltage Test

A ***regulator voltage test*** checks the calibration of the voltage regulator and detects a high or low voltage setting.

To perform this test, use the following procedure:

1. Set the load tester controls to the correct test position.
2. With the load control off, run the engine at 2000 rpm or at the specified test speed.
3. Note the voltmeter reading and compare it to specifications.

Most voltage regulators are designed to operate with a voltage of 13.5–14.5 volts. This range applies to a fully charged battery at normal temperature.

If the meter reading is steady and within recommended values, then the regulator setting is correct. If the voltage is steady but too high or too low, then the regulator may need adjustment or replacement. If the reading is not steady, there may be a bad wiring connection, an alternator problem, or a defective regulator.

If a charging system fails either the output test or the regulator voltage test, a regulator bypass test should be performed.

Regulator Bypass Test

A ***regulator bypass test*** is a quick and easy way of finding if the alternator, regulator, or circuit is faulty. Procedures for a regulator bypass test are similar to the those for the output test already explained. However, the regulator is taken out of the circuit.

Depending on system design, there are several ways to bypass the voltage regulator. If the rear of the alternator has a test tab, short it on the end frame, **Figure 34-6.** When the tab is shorted, the alternator should produce maximum output. With many vehicles, a jumper wire must be used to connect battery and field terminals, **Figure 34-7.** When the battery voltage (unregulated voltage) excites the rotor field, the alternator should produce maximum output.

Caution!
Follow manufacturer's directions to avoid damage when bypassing the voltage regulator. You must not short or connect voltage to the wrong wire, or the diodes or regulator may be ruined.

Regulator Bypass Test Results

If charging voltage and current increase to normal levels when the regulator is bypassed, you usually have a bad regulator. If system output remains the same when the regulator is bypassed, you normally have a bad alternator.

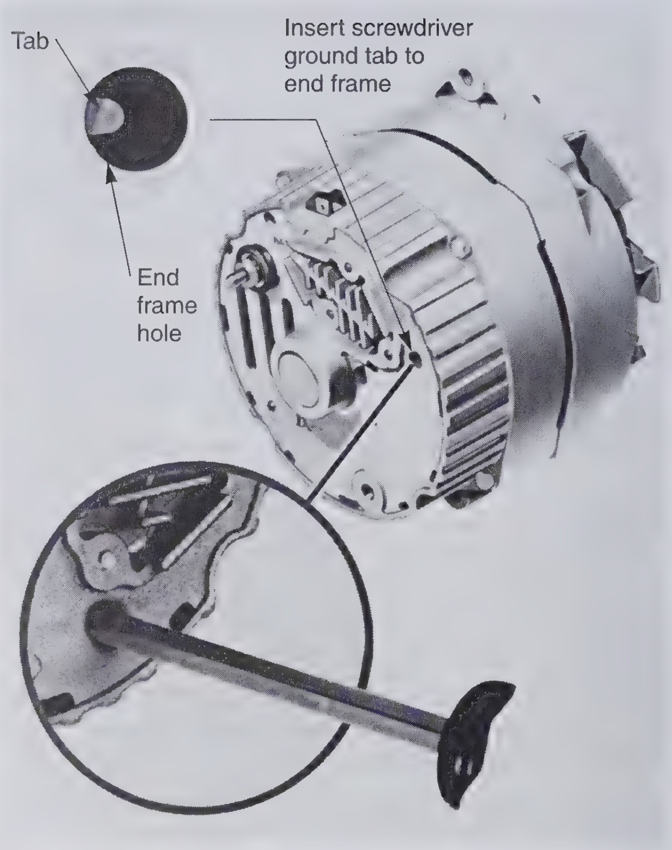

Figure 34-6. If charging system fails the current output test, bypass the regulator to pinpoint the problem. The shorting tab on this alternator should make the alternator produce maximum output. If it does, the regulator is bad. If it does not, then the alternator may be bad. (Pontiac)

Specialized charging system testers may have other test modes (positions). For example, they may be able to check the alternator stator, diodes, or regulator. Read the tester instructions.

Charging System Scope Testing

The vehicle's computer can also be used to control and/or monitor the charging system alternator by replacing or supplementing the voltage regulator. Basically, the computer controls the duty cycle of the alternator's field.

The *duty cycle* is the percentage of time that current is fed to the alternator's field windings. With a large electrical load, the duty cycle would be high (long) to make the alternator produce high output. A duty cycle of 50% is normal.

In some charging systems with internal voltage regulators or computer-controlled regulation, the regulators

Jumper wire connected to alternator "BAT" and "FLD" terminals

Figure 34-7. Other methods of bypassing the regulator to find out if the alternator or the regulator is faulty. (Mercury)

cannot be bypassed and full-fielded. This makes it more difficult to isolate a low-charging problem to the alternator or the voltage regulator. When testing these systems, you must use a scope or load tester with a diode test function to check for abnormal voltage ripple (indicating bad alternator diodes).

A charging system ***scope test*** involves analyzing the alternator voltage waveform for signs of abnormal ripple.

Use the following procedure when performing a scope test:

1. Connect the scope to the alternator output terminal.
2. Ground the other scope lead.
3. Start the engine and observe the scope trace (waveform).

As shown in **Figure 34-8,** the charging system should produce a relatively smooth dc voltage trace with minimum ripple. **Figure 34-9** shows both good and bad scope waveforms for typical charging systems.

Note!
For more information on these tests, refer to Chapter 46, *Advanced Diagnostics.*

Circuit Resistance Tests

Circuit resistance tests are used to locate wiring problems in a charging system: loose connections, corroded terminals, partially burned wires, and similar troubles. Resistance tests should be performed when symptoms point to problems other than the alternator or regulator. Two common circuit resistance tests are the insulated-circuit resistance test and ground-circuit resistance test.

Figure 34-8. A hand-held oscilloscope can be connected to the alternator to check for smooth dc output. This scope will show a digital readout of the voltage and a voltage trace. With a good charging system, there should be very little ripple in the trace. (Fluke)

To do an ***insulated-circuit resistance test*** on a charging system, connect the tester as described by the manufacturer. One type of connection is shown in **Figure 34-10.** Note how the voltmeter leads are

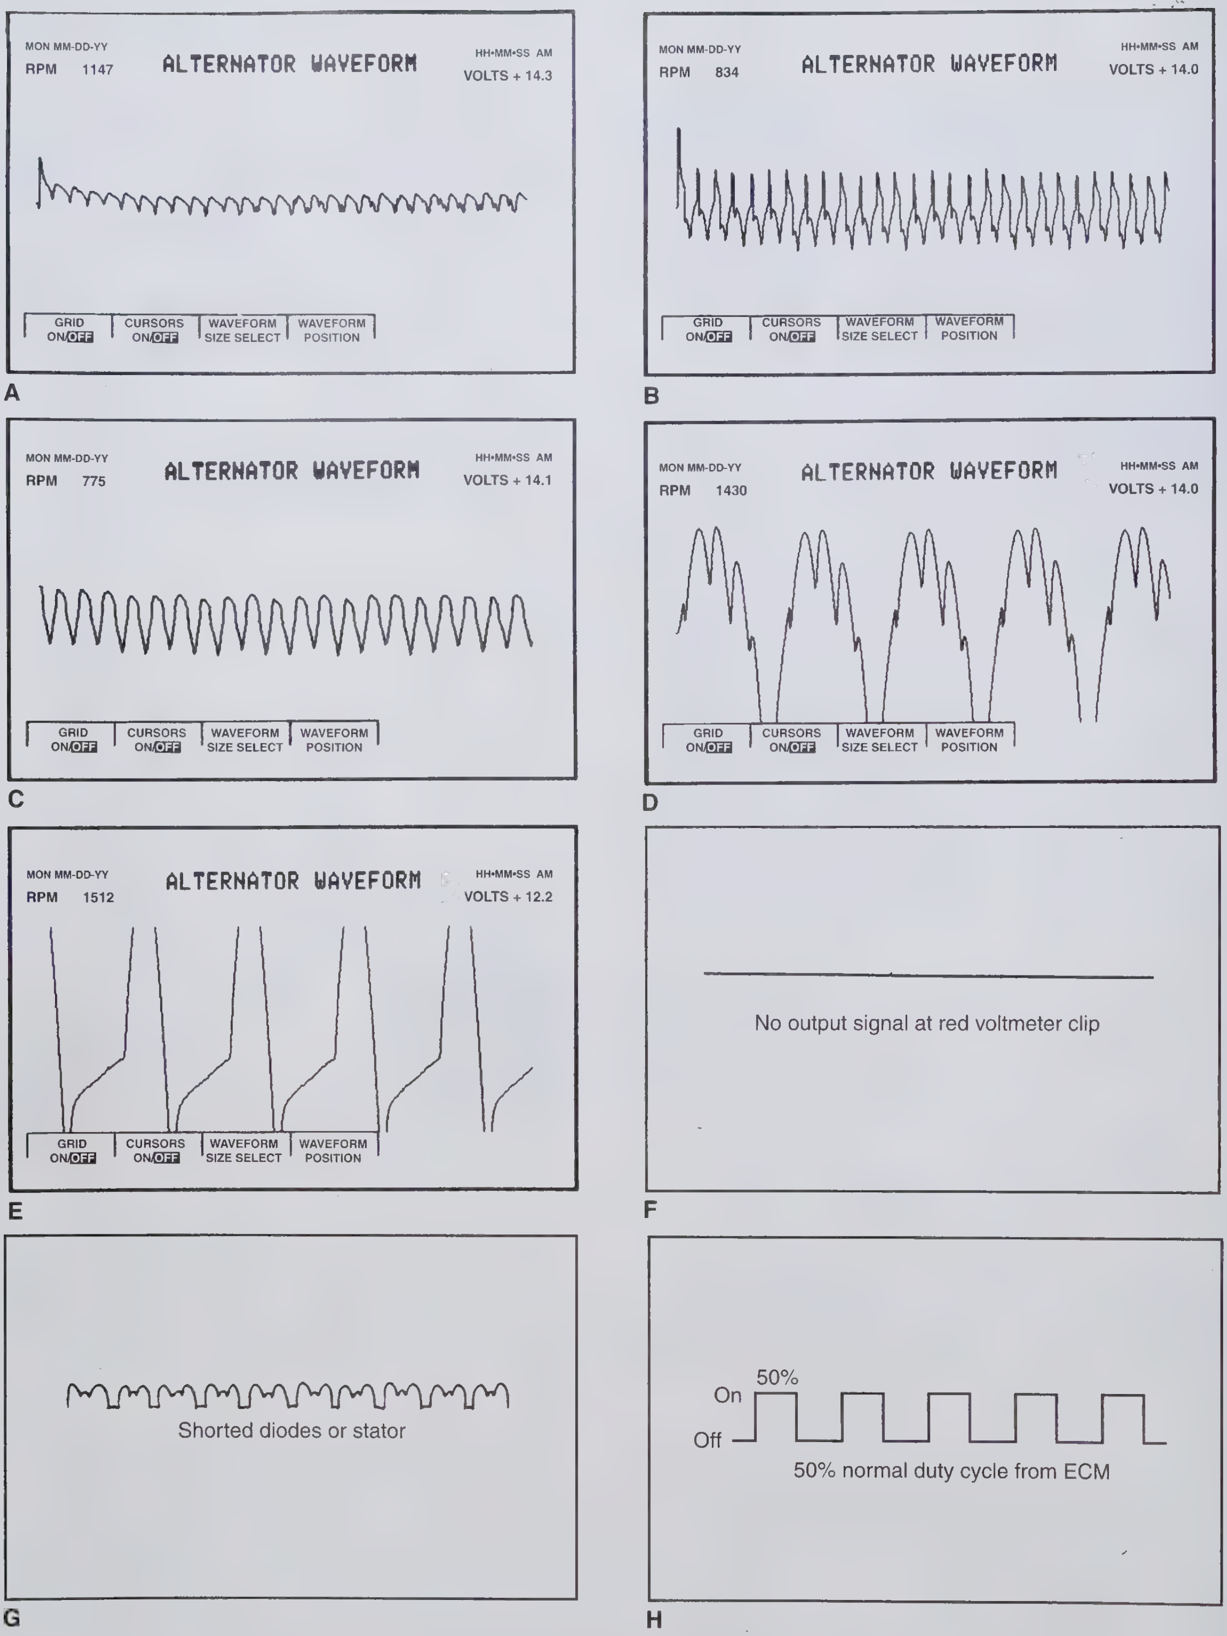

Figure 34-9. Oscilloscope will show faulty diodes and other problems before alternator removal and tear down. A—Normal alternator waveform with typical output. Note small, regularly spaced, even ripples. B—This is normal light load alternator waveform with some electronic regulators using duty cycles to control output. Slightly higher inductive peaks and spike can be normal with some systems. C—Normal alternator waveform with heavy load from a dead battery or many accessories on. It is similar to *A* but has a higher amplitude ripple from increased current output. D—This alternator waveform shows an open diode causing high spikes. E—This waveform is due to one open diode and one shorted diode. F—A solid straight line on scope indicates no output from the alternator. G—This waveform indicates shorted diodes or shorted stator windings. H—Duty cycle from ECU to alternator field windings can be checked with a scope. High load, as applied from load tester, should make duty cycle show more On time. If not, suspect the computer. (Snap-On Tools)

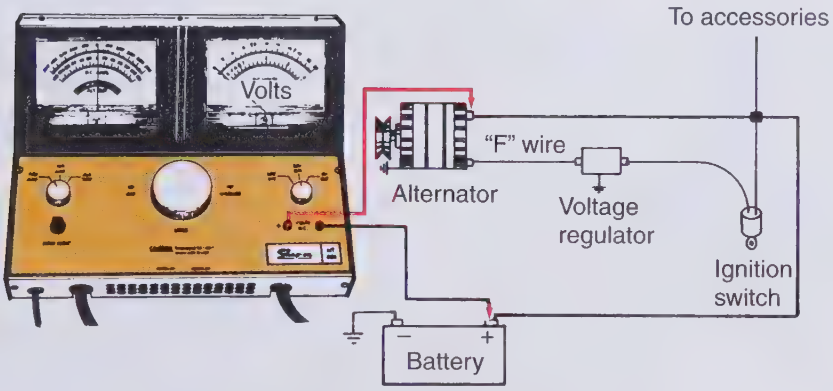
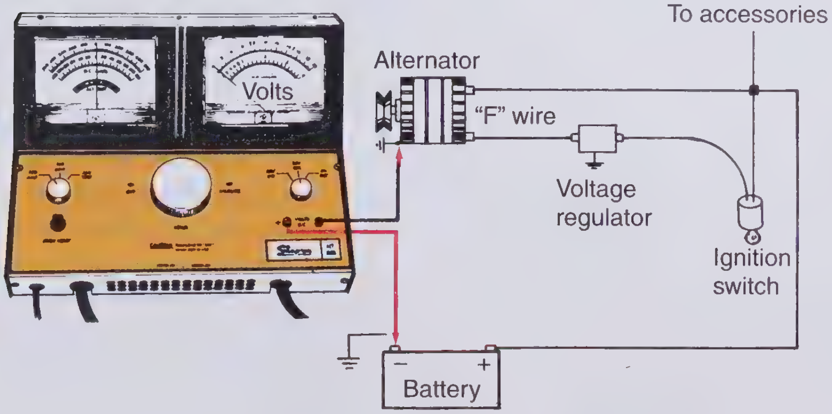


Insulated-circuit resistance test



Ground-circuit resistance test

Figure 34-10. Voltage drop or resistance tests will find problems in wiring. (Snap-On Tools)

connected across the alternator output terminal and positive battery terminal.

With the vehicle running at a fast idle, turn the load control to obtain a 20 amp current flow. All lights and accessories should be off. Read the voltmeter.

If the circuit is in good condition, the voltmeter should not read over about 0.7 volts (0.1 volt per electrical connection). If the voltage drop is higher than 0.7 volts, circuit resistance is high. A poor connection exists in that section of the charging circuit.

A ***ground-circuit resistance test*** is similar to the insulated-circuit resistance test. However, the voltmeter is placed across the negative battery terminal and alternator housing. See **Figure 34-10.**

The voltmeter should not read over 0.1 volt per electrical connection. If the voltmeter reading is higher, look for loose connections, a burned plug socket, or similar problems.

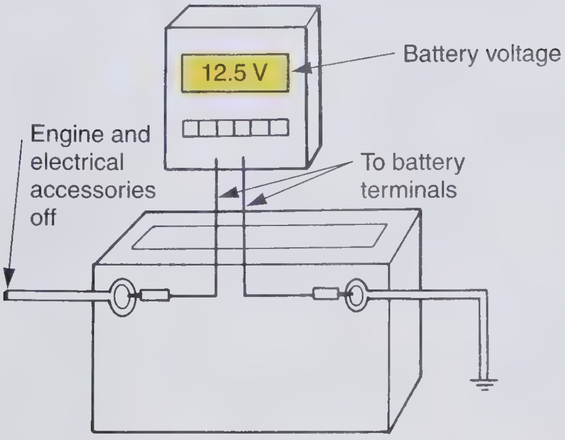
Voltmeter Test of Charging System

A voltmeter can also be used to test the output of a charging system when a load tester is not available. It will measure charging system voltage with an accessory load (all electrical accessories on). The voltage reading will be an indicator of current output and charging system condition. If charging system output voltage is not above battery voltage, the battery cannot be recharged and a problem exists.

A voltage test involves four steps. Refer to **Figure 34-11.**

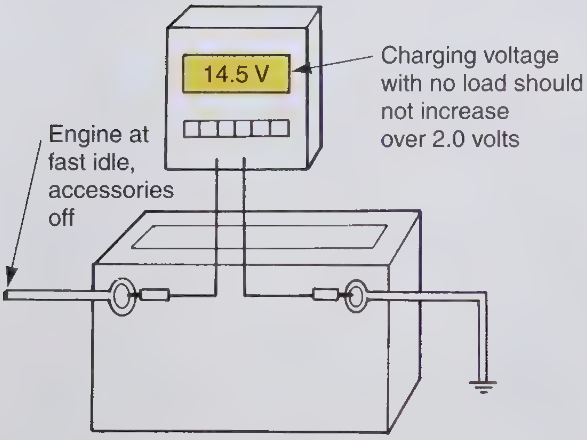
1. Measure ***base voltage—***battery voltage with the engine off.
2. Measure ***no-load voltage—***battery voltage with the engine running and electrical accessories off.
3. Measure ***load voltage—***battery voltage with the engine running and all electrical accessories on.
4. Calculate ***charge voltage—***load voltage - base voltage = charge voltage. Charge voltage should be 0.5 volts higher than battery voltage.

The load voltage must be higher than the base voltage for battery charging. No-load voltage must be within specifications.



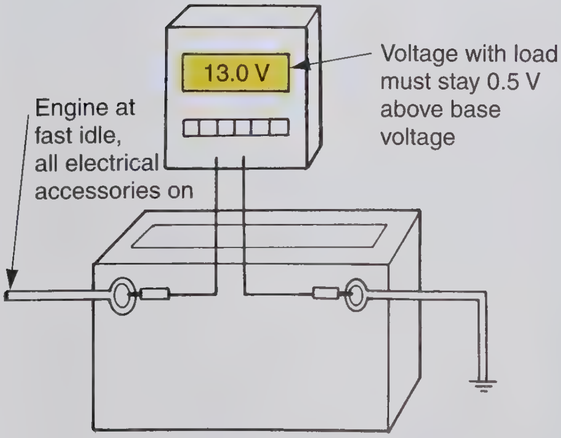
12.5 V
Battery voltage
Engine and electrical accessories off
To battery terminals

Base voltage



14.5 V
Charging voltage with no load should not increase over 2.0 volts
Engine at fast idle, accessories off

No-load voltage



13.0 V
Voltage with load must stay 0.5 V above base voltage
Engine at fast idle, all electrical accessories on

Load voltage

Figure 34-11. If a load tester is not available, a voltmeter can be used to test the charging system output. The electrical accessories are turned on to make sure the voltage stays high enough to charge the battery.

Base Voltage

When testing the charging system with a voltmeter, connect the meter probes across the terminals of the battery to measure the base voltage. This reading will compensate for any variation in the condition of the battery and accuracy of your meter. With a good, fully charged battery, the base voltage reading should be around 12.6 volts.

No-Load Voltage

A no-load test measures the charging system voltage with no current draw. Start and run the engine at about 1500 rpm with all electrical accessories off. The voltmeter reading should increase from the base reading, but not by more than two volts.

A no-load voltage that is 0.5–2 volts higher than the base voltage is normal. For example, if your base voltage is 12.5 volts, your no-load reading should be 13.0–14.5 volts. If the no-load voltage is more than 2–3 volts higher than base voltage, the alternator is overcharging the battery. Either the voltage regulator or wiring is bad.

If the no-load voltage reading is not higher than the base voltage, the charging system is not working. The alternator, regulator, or wiring may be bad. Bypass the regulator or perform resistance tests to isolate the problem.

Load Voltage

If the system passes the no-load voltage test, you should also complete a load test with your voltmeter. This will check the charging system output under high-current draw conditions. The load test shows if the charging system is providing current for all the electrical units and still has enough current to recharge the battery.

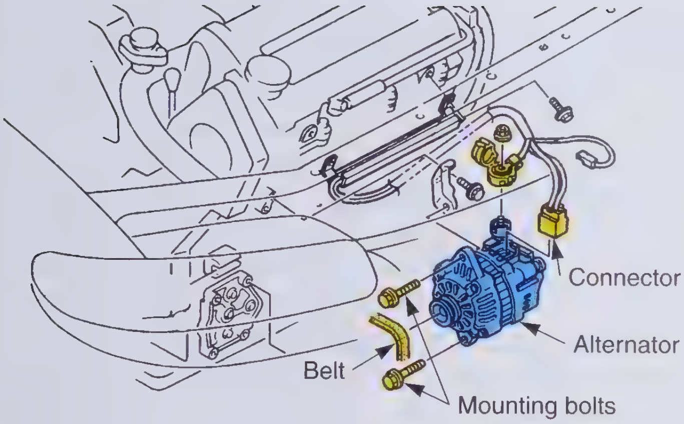
Start the engine and run it at about 2000 rpm. To load the charging system, turn on all electrical accessories (headlights, wipers, blower motor, air conditioning, etc.). The voltmeter should read at least 0.5 volts higher than the base voltage. If the load voltage is not 0.5 volts above the base voltage, bypass the regulator to determine which component (alternator or regulator) is faulty.

Alternator Service

A bad alternator will show up during your tests as a low voltage and current output problem. Even when the regulator is bypassed and full voltage is applied to the alternator field, charging voltage and current will not be up to specifications.

Alternator Removal

Before unbolting the alternator, disconnect the battery to prevent damage to parts if wires are shorted. As shown in **Figure 34-12,** most alternators are attached to



Connector
Alternator
Belt
Mounting bolts

Figure 34-12. To remove the alternator, first remove parts that block access to the alternator mounting bolts. Then loosen bolts and slide the belt off the pulley. Disconnect wires and remove the bolts. (Mazda)

the front of the engine with two or three bolts. Loosen the bolts and remove the belt. Then remove the alternator.

When removing the wires from the back of the alternator, note their location and whether special insulating washers are used. If you make a mistake in reattaching wires to the alternator, system damage can occur.

Depending on vehicle design, the alternator may come out from the top or bottom of the engine compartment. If it must be removed from the bottom, you may need to remove a splash shield to gain access to the alternator mounting brackets and bolts.

Alternator Disassembly

To disassemble an alternator, first scribe marks on the outside of the housing. This will aid you in reassembly. When clamping the alternator in a vise, be careful not to damage the housing or bend the fan.

Follow the directions in a shop manual when disassembling the alternator. **Figure 34-13** illustrates the basic disassembly steps. An Allen wrench may be needed to hold the shaft. Use a puller, if needed, to remove the pulley.

Remove the alternator through-bolts. Tap the drive end frame with a plastic or brass mallet. Slide the end frame from the rotor shaft. As you remove the remaining alternator parts, watch how everything fits together.

Replace bearings

Figure 34-13. Basic steps for alternator disassembly. (Honda, Subaru, DaimlerChrysler)

Tech Tip!
Depending on the type of repair, you may not need to completely disassemble the alternator. For example, when replacing worn alternator bearings, you do not have to remove the diodes, built-in regulator, or other unrelated parts.

Keep all your parts organized and clean, **Figure 34-14.** If you get grease on the brushes, replace them. Grease or oil will ruin the brushes.

Caution!
Do not soak the rotor, stator, diode pack, regulator, or other electrical components in solvent. Solvent can ruin these components.

Alternator Rotor Service

A bad alternator rotor can have a bent shaft, scored slip rings, open windings, or shorted windings. Visually inspect the rotor closely. Make sure the rotor is in good condition before assembling the alternator. There are several tests designed to check an alternator rotor. Refer to **Figure 34-15.**

Current test

Figure 34-15. Alternator rotor tests. (DaimlerChrysler)

A ***rotor winding short-to-ground test*** measures resistance between the rotor shaft and the windings. The ohmmeter should read infinite (maximum) resistance to show no short to ground.

A ***rotor winding open circuit test*** measures the resistance between the two slip rings. The meter should read low resistance (2–4 ohms). This would indicate that the windings are not broken.

A ***rotor current test*** checks the windings for internal shorts. Connect a 12-volt battery and an ammeter to the slip rings. Measure the current and compare it to specifications. Typical rotor current should be 3–6 amps. Replace the alternator rotor if it fails any of these three tests.

Alternator Stator Service

A bad alternator stator can have shorted or open windings. Inspect the stator windings for signs of burning (darkened windings with a burned insulation smell). An open winding is usually detected using an ohmmeter.

To test a stator for open or grounded windings, connect an ohmmeter to the stator leads as shown in **Figure 34-16.** Connections A and B will check for stator opens. They should produce a low ohmmeter reading. If the reading is high (infinite), the windings are broken and the stator is defective.

Connection C tests for a grounded winding. An infinite reading is desirable. If the reading is low, the stator is grounded and should be replaced.

Alternator Diode Service

Bad alternator diodes reduce alternator output current and voltage, and may also cause voltage ripple that can upset computer system operation. Faulty diodes are a frequent cause for alternator failure. It is important to check the condition of the diodes when rebuilding an alternator.

There are various methods used to test alternator diodes: ohmmeter, test light, diode tester, and scope test. The ohmmeter is the most common testing tool used when the alternator is disassembled.

When using an ohmmeter or a test light, the diodes must be unsoldered and isolated from each other. Some special diode testers, however, will check the condition of the diodes with all the diodes still connected to each other.

Ohmmeter Test of Diodes

To use an ohmmeter to test the diodes, connect the meter to each diode in one direction and then the other, **Figure 34-17.** The meter should read high resistance in one direction and low resistance in the other. This will show you that the diode is functioning as an "electrical check valve." The test should be performed on each diode.

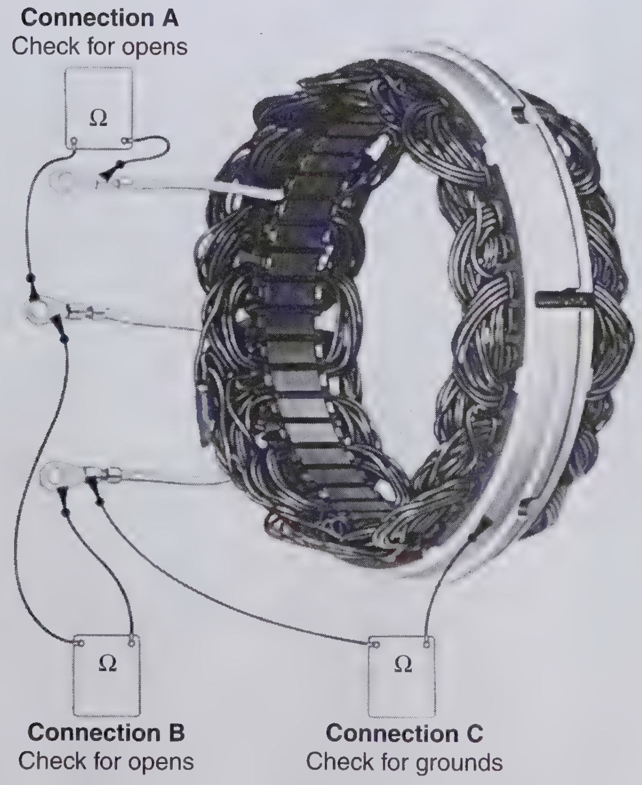

Figure 34-16. Stator tests. Connect an ohmmeter for three tests to check windings. (Chevrolet)

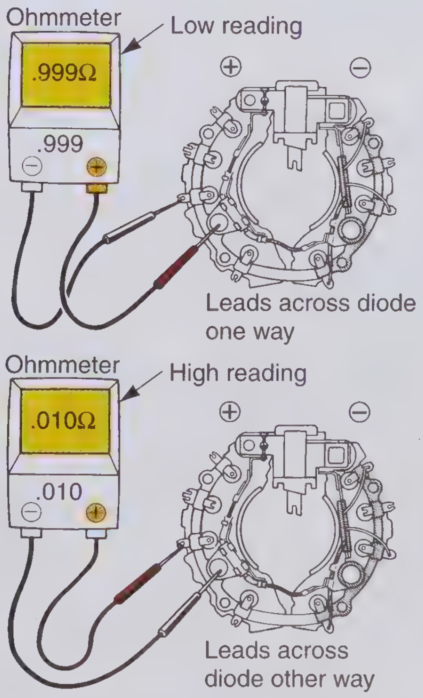

Figure 34-17. To test diodes with an ohmmeter, connect the leads one way and then the other. The meter should read high ohms in one direction and low in the other. (Toyota)

A bad diode can either be shorted or opened. An ***open diode*** will have a high (infinite) resistance in both directions. A ***shorted diode*** will have a low (zero) resistance in both directions. In either case, the diode must be replaced. Press in a new diode or obtain a new diode pack.

If diodes were unsoldered for testing or replacement, they must be resoldered. Use a soldering gun and rosin-core solder to attach the diode leads, **Figure 34-18.** Heat the wires quickly to avoid overheating the diodes. Excess heat can ruin a diode.

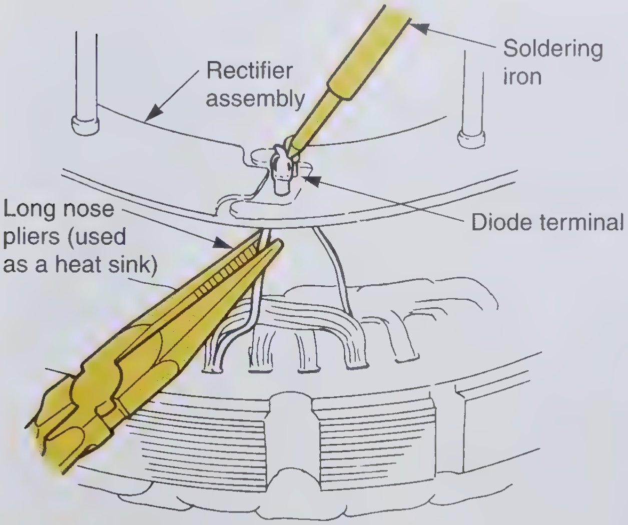

Figure 34-18. Use rosin-core solder to join the diode leads, or stator-to-rectifier wires.

Alternator Bearing Service

Worn alternator bearings and ***dry alternator bearings*** produce a rumbling or grinding noise during operation. They can become loose enough to upset alternator output by allowing too much rotor shaft movement. When rebuilding an alternator, it is common practice to replace the bearings.

The front alternator bearing, also called the drive end bearing, is usually held in place with a cover plate and small screws. To replace the bearing, remove the screws and plate and lift out the old bearing.

The rear alternator bearing, also referred to as the diode end bearing or slip ring end bearing, is normally pressed into the rear end housing. It may be pressed or carefully driven out of the alternator housing for replacement.

If the bearings are relatively new and you do not replace them, make sure you put a moderate amount of grease into the rear bearing. The front bearing is usually sealed and cannot be greased.

To check the action of the front bearing, rotate it with your finger while feeling for roughness or dryness. Replace the bearing if there is any sign of failure.

Alternator Brush Service

Worn brushes can affect the output voltage and current of an alternator. As the brushes wear, spring tension and brush pressure on the slip rings will be reduced.

Inspect the brushes and measure their length. When the brushes are worn beyond specifications or soaked with oil or grease, replace them. Many technicians simply replace the brushes whenever the alternator is disassembled.

Alternator Assembly

After you have inspected and tested the components of an alternator, you are ready for reassembly. Alternator construction varies; refer to a service manual describing the particular unit. In general, assemble the alternator in the reverse order of disassembly. Study **Figure 34-19.**

The following procedure is typical for alternator assembly:

1. Install all the components in the rear end frame: electronic regulator, diode pack, rear bearing, terminals, and nuts.
2. If the brushes are not mounted on the outside rear of the end frame, you may need to use a piece of *stiff wire* or a *small Allen wrench* to install the brushes. Push the brush spring and brush into place, **Figure 34-20.** Then, slide your wire or Allen wrench into a hole in the rear end frame. Push the next spring and brush into place. Slide the wire the rest of the way through the hole. The wire or Allen wrench will hold the brushes out of the way as you slide the rotor into the housing.
3. Fit the front end frame into position and check the alignment pins or marks. Install and tighten the through-bolts.
4. Pull out the piece of wire or Allen wrench. You should hear the brushes click into place on the slip rings.
5. Install any spacer, the fan, front pulley, lock washer, and nut. Torque the pulley nut to specifications, **Figure 34-21.** Then, spin the rotor shaft and pulley to check for free movement. The rotor should spin freely without making unusual noises.

Test alternator output on a ***bench tester*** (unit for off-car output test of alternator) if one is available. If not, test the charging system output after alternator installation.

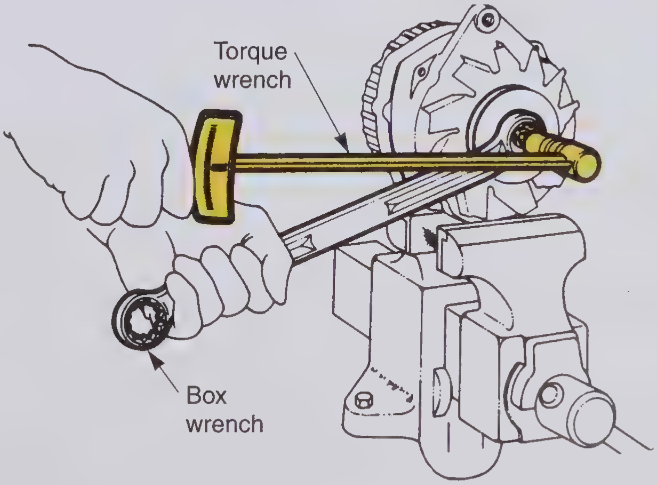
Bottom. The wire will hold brushes as you fit the rotor into position. Slide the wire out and the brushes will snap into contact with the slip rings.

Alternator Installation

With the battery still disconnected, fit the alternator onto the front of the engine. If needed, install the wires on the back of the alternator first. Hand start the bolts and screw them in without tightening.



Torque wrench
Box wrench

Figure 34-21. Use a torque wrench to properly tighten the pulley nut. Be careful not to damage the alternator housing or fan in the vise. (DaimlerChrysler)

Check the condition of the alternator belt. Replace it if needed. Slip the belt over the engine and alternator pulley. Make sure the belt is aligned properly on each pulley. Adjust belt tension and tighten the bolts. Reconnect the battery.

Regulator Service

When a modern electronic regulator fails a voltage test, it must be replaced. However, with older contact-point regulators, you can often simply adjust the regulator setting.

Electronic Regulator Service

It is a simple task to replace a faulty electronic regulator. The electronic regulator is normally located on the back of the alternator or inside the alternator. If not, it may also be located on a fender well.

Obtain the correct replacement regulator and install it. Then recheck charging system output.

Some electronic voltage regulators are adjustable. They can have a small adjusting screw inside a hole in the outer case. Turning the screw will adjust the voltage setting of the regulator. Check a shop manual for details.

Normally, the engine is run at idle with a voltmeter connected to measure no-load charging voltage. The regulator screw is rotated until the voltmeter reads within specifications.

Contact-Point Regulator Service

Contact-point regulators were used on dc generator and early alternator charging systems. The regulator, due to point wear and pitting, is a common cause of problems.

If you work on a car equipped with a contact-point regulator, refer to the service manual. Regulator operation and circuits vary. You will need a manual covering the exact type of regulator circuit. It will tell you how to file, test, and adjust the regulator points. If the regulator cannot be adjusted to obtain the proper voltage, replace it.

Computer Voltage Regulator Service

As discussed in the previous chapter, some alternators use an on-board computer or power train control module to control charging system output. To check this type system, use a scope to check the duty cycle and voltage being applied to the alternator field windings. You may also find poor electrical connections between the electronic control unit and the alternator.

With computer control of the alternator, charging voltage can be slightly lower than normal. However, charging voltage must still stay above battery voltage.

If an abnormal signal or no signal is being sent out of the control unit to the alternator, the regulator should be replaced. Refer to the service manual for more specific testing and servicing methods.

Duff's Garage

Problem: Mr. Howard brings his 1993 Buick LeSabre to the shop, complaining that it has to be jump started every time he wants to drive it. He adds that he bought and installed a new battery to correct a no-start problem, but the car still will not start properly.

Diagnosis: Duff inspects the alternator belt, the alternator, the alternator wiring, and the battery connections. Not finding a problem during the visual inspection, Duff turns the repair over to the shop's electrical technician.

The technician charges the battery in preparation for making electrical tests. He connects a voltmeter across the battery terminals. The meter shows a base voltage reading of 12.6 volts, indicating that the battery is fully charged.

The technician then checks no-load voltage. He starts the engine, makes sure all the electrical accessories are off, and runs the engine at fast idle. At fast idle, the voltmeter still reads 12.6 volts, indicating that the charging system is not working properly.

The technician bypasses the voltage regulator to determine if the regulator is causing the problem. However, bypassing the regulator does not cause the no-load voltage to increase. The technician then attaches an oscilloscope across the battery cables and observes large voltage spikes, which are a sign of alternator diode failure.

Repair: The technician removes and disassembles the alternator. Further testing reveals that two diodes are bad. The technician rebuilds the alternator, replacing the diodes and brushes. He then reinstalls the alternator and rechecks charging system voltage. After determining that the system is working properly, he releases the vehicle to the customer.

Summary

- Sometimes, another system fault (bad starting motor, battery, computer failure, or wiring) will appear to be caused by problems in the charging system.
- A loose drive belt may squeal or flap and may prevent normal charging.
- Listen closely for abnormal noises in the alternator. Use a stethoscope to listen to the alternator if necessary.
- A charging system output test measures system current and voltage under maximum load (current output).
- A regulator voltage test will check the calibration of the voltage regulator and detect an improper voltage setting.
- A regulator bypass test is a quick and easy way of finding if the alternator, regulator, or circuit is faulty.
- Duty cycle is the percentage of time that current is fed to the alternator's field windings.
- Circuit resistance tests are used to locate wiring problems in a charging system.
- A bad alternator will show up during your tests as a low voltage and current output problem.
- Bad alternator diodes reduce alternator output current, output voltage, and may also cause voltage ripple that can upset computer system operation.
- With a computer-controlled alternator, charging voltage can be slightly lower than normal.

Review Questions—Chapter 34

Please do not write in this text. Place your answers on a separate sheet of paper.

1. Name four common symptoms caused by charging system problems.
2. Overtightening an alternator belt is a common mistake that ruins the alternator bearings. True or False?
3. List and explain five charging system service precautions.
4. List and explain four common charging system tests.
5. A(n) _____ _____ is an instrument that provides the most accurate method of checking the condition of a charging system.
6. A charging system output test measures system _____ and _____ under maximum conditions.
7. Depending upon alternator rating, charging system output can range from 35–80 amps. True or False?
8. Most voltage regulators are designed to maintain between 11 and 12 volts. True or False?
9. Explain the regulator bypass test.
10. A charging system has failed the output and regulator voltage tests. Voltage and current were too low. All belts, electrical connections, and other visible checks were OK. Technician A says that a regulator bypass test should be done next to help isolate the problem to the alternator, regulator, or circuit wiring. Technician B says that the alternator should be removed and tested on a bench. This will eliminate any wiring or circuit troubles. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
11. What is the purpose of charging system circuit resistance tests?
12. Charging system testers and an oscilloscope can be used to help diagnose charging system troubles. True or False?
13. A bad alternator rotor can have:
    (A) a bent shaft.
    (B) scored slip rings.
    (C) open windings.
    (D) All of the above.
14. Explain three rotor tests.
15. How do you test a stator?

ASE-Type Questions

1. When working on charging systems, all of the following precautions should be taken, except:
   - *(A) never reverse polarity.*
   - *(B) always polarize the alternator.*
   - *(C) never short system terminals.*
   - *(D) detach the battery before part removal.*
2. Each of these is a common charging system test *except:*
   - *(A) regulator bypass test.*
   - *(B) circuit resistance tests.*
   - *(C) alternator mounting test.*
   - *(D) charging system output test.*
3. In which test(s) is the regulator left out of circuit?
   - *(A) Regulator bypass test.*
   - *(B) Regulator voltage test.*
   - *(C) Circuit resistance tests.*
   - *(D) None of the above.*
4. Charging system tests are performed using a(n):
   - *(A) VOM.*
   - *(B) scope.*
   - *(C) load tester.*
   - *(D) All of the above.*
5. Most voltage regulators operate in this volt range:
   - *(A) 10–12 volts.*
   - *(B) 13.5–14.5 volts.*
   - *(C) 30.2–35.2 volts.*
   - *(D) 40.5–80.5 volts.*
6. Technician A believes that if charging voltage and current increase to normal levels during a regulator bypass test, the regulator is bad. Technician B feels such results will indicate a bad alternator. Who is right?
   - *(A) A only.*
   - *(B) B only.*
   - *(C) Both A and B.*
   - *(D) Neither A nor B.*
7. The percentage of time that current is fed to the alternator's field windings is called the:
   - *(A) feed time.*
   - *(B) duty cycle.*
   - *(C) circuit term.*
   - *(D) charge ratio.*
8. During a charging system voltmeter test, all electrical accessories are *on* when checking:
   - *(A) base voltage.*
   - *(B) load voltage.*
   - *(C) no-load voltage.*
   - *(D) All of the above.*
9. Which part should *not* be soaked in solvent during alternator disassembly?
   - *(A) Rotor.*
   - *(B) Stator.*
   - *(C) Diode pack.*
   - *(D) All of the above.*
10. Which of the following inspections checks rotor windings for internal shorts?
    - *(A) Rotor current test.*
    - *(B) Rotor winding open circuit test.*
    - *(C) Rotor winding short-to-ground test.*
    - *(D) All of the above.*

Activities—Chapter 34

1. Make a poster for classroom display showing the steps involved in checking a charging system with a voltmeter.
2. Demonstrate the use of a stiff wire to hold brushes in place when reassembling an alternator.

Charging System Diagnosis

Condition	Possible cause	Correction
No charge.	1. Alternator drive belt loose or broken.	1. Tighten or replace belt.
	2. Voltage regulator fusible link blown.	2. Install new fusible link.
	3. Sticking or worn commutator brushes.	3. Free or replace brushes.
	4. Loose or corroded connection.	4. Clean and solder connections.
	5. Rectifiers open.	5. Correct cause and replace rectifiers.
	6. Charging circuit open.	6. Correct as needed.
	7. Open circuit in stator winding.	7. Replace stator.
	8. Field circuit open.	8. Test and correct as required.
	9. Defective field relay.	9. Replace relay.
	10. Defective voltage regulator.	10. Replace voltage regulator.
	11. Open isolation diode.	11. Replace diode.
	12. Open resistor wire.	12. Replace resistor wire.
	13. Slipping drive pulley.	13. Install new key and tighten.
	14. Oil soaked brushes.	14. Replace brushes.
	15. Corroded or loose brush connections.	15. Clean and tighten connections.
	16. Seized bearings.	16. Replace bearings. Check shaft for damage.
Low or erratic rate of charge.	1. Loose drive belt.	1. Tighten belt.
	2. Open stator; grounded or shorted turns in stator windings.	2. Replace stator.
	3. High resistance in battery terminals	3. Clean and tighten terminals.
	4. High resistance in charging circuit.	4. Repair cause of high resistance.
	5. Engine ground strap loose or broken.	5. Tighten or replace strap.
	6. Loose connections.	6. Tighten connections.
	7. Defective rectifier.	7. Replace rectifier.
	8. Dirty, burned slip rings.	8. Turn slip rings.
	9. Grounded or shorted turns in rotor.	9. Replace rotor.
	10. Brushes worn. Brush springs weak.	10. Replace brushes and/or springs.
Excessive rate of charge.	1. Faulty voltage regulator ground.	1. Ground regulator properly.
	2. Defective voltage regulator.	2. Replace regulator.
	3. Alternator field winding grounded.	3. Repair grounded field winding.
	4. Open rectifier.	4. Replace rectifier.
	5. Loose connections.	5. Tighten connections.
Noise.	1. Drive belt slipping.	1. Tighten belt.
	2. Drive pulley loose or misaligned.	2. Tighten or align pulley.
	3. Mounting bolts loose.	3. Tighten mounting bolts.
	4. Worn bearings.	4. Replace bearings.
	5. Dry bearing.	5. Lubricate or replace as required.
	6. Open or shorted rectifier.	6. Replace rectifier.
	7. Sprung rotor shaft.	7. Install new rotor.
	8. Open or shorted stator winding.	8. Test. Replace stator as needed.
	9. Alternator fan dragging.	9. Adjust fan clearance.
	10. Excessive rotor end play.	10. Adjust for correct end play.
	11. Out-of-round or rough slip rings.	11. Turn slip rings.
	12. Hardened brushes.	12. Replace brushes.

(Continued)

Charging System Diagnosis

Condition	Possible cause	Correction
Undercharged battery.	1. No charge or low charge rate. 2. Excessive use of starter. 3. Defective battery. 4. Excessive resistance in charging circuit. 5. Defective alternator. 6. Defective regulator. 7. Electrical load exceeds alternator rating. 8. Electrical draw in system. 9. Excessive starter motor draw.	1. See *No charge* or *Low or erratic rate of charge.* 2. Recharge battery. Advise owner. 3. Replace battery. 4. Test circuit and remove resistance. 5. Rebuild or replace alternator. 6. Replace regulator. 7. Reduce load or install higher capacity alternator. 8. Test. Remove source of electrical draw. 9. Rebuild or replace starter motor.
Overcharged battery.	1. Excessive resistance in voltage regulator circuit. 2. Regulator-alternator ground wire loose or open. 3. Defective battery. 4. Defective regulator.	1. Clean and tighten connections. 2. Tighten or replace wire. 3. Replace battery. 4. Replace regulator.

35
Ignition System Fundamentals

After studying this chapter, you will be able to:

- Explain the operating principles of an automotive ignition system.
- Compare contact point, electronic, and computer-controlled ignition systems.
- Describe the function of major ignition system components.
- Explain vacuum, centrifugal, and electronic ignition timing advance.
- Sketch the primary and secondary sections of an ignition system.
- Compare ignition coil, spark plug, and distributor design variations.
- Describe the safety practices that must be followed when working with ignition systems.
- Correctly answer ASE certification test questions that require a knowledge of ignition system fundamentals.

The ignition system of a spark-ignition engine produces the high voltage needed to ignite the fuel charges in the cylinders. The system must create an electric arc across the gaps at the spark plugs. These arcs must be timed so they happen exactly as each piston nears the top of its compression stroke. The heat of the arcs starts combustion and produces the engine's power stroke.

In recent years, different types of ignition systems have been developed to reduce emissions and improve engine performance, fuel economy, and dependability. This chapter explains electronic, computer-coil (distributorless), and direct ignition systems by comparing them to older, simple contact point systems. This should give you a sound knowledge of all automotive ignition system types.

Note!
Several other sections of this book discuss information relevant to ignition systems. Chapter 8 summarized basic electrical-electronic components. Chapters 17–19 describe computer system operation, diagnosis, and repair. Refer to these chapters as needed.

Functions of an Ignition System

An ignition system performs the following six functions:

- Provides a method of turning a spark ignition engine *on* and *off.*
- Operates on various supply voltages (battery or alternator voltage).
- Produces high-voltage arcs at the spark plug electrodes to start combustion.
- Distributes high-voltage pulses to each spark plug in the correct sequence.
- Times the spark so that it occurs as the piston nears TDC on the compression stroke.
- Varies spark timing as engine speed, load, and other conditions change.

Basic Ignition System

An ***ignition system*** changes battery voltage to a very high voltage and then sends the high voltage to the spark plugs, **Figure 35-1.** The parts needed to do this include the following:

- ***Battery***—provides power for system.

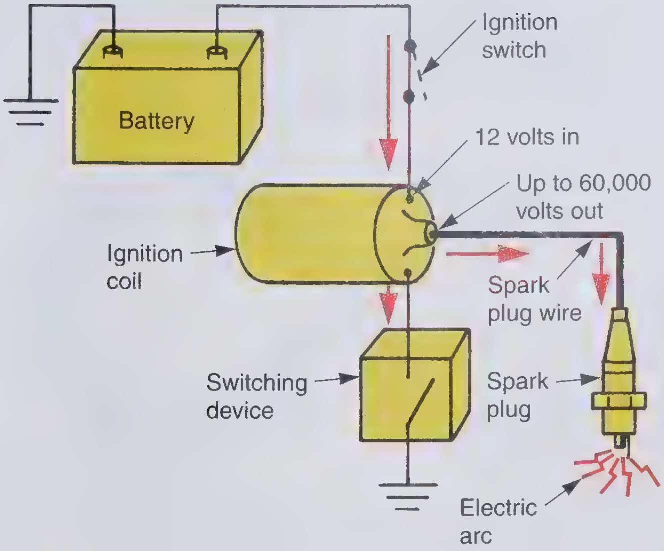

Figure 35-1. Study the operation of a basic ignition system for a one-cylinder engine. Battery voltage is stepped up to about 15,000 volts by the coil before it is sent to the spark plug. The switching device can be a set of breaker points or, more commonly, an electronic switching circuit.

- ***Ignition switch***—allows driver to turn ignition and engine on and off.
- ***Ignition coil***—changes battery voltage into 30,000 volts or more during normal operation. It has the potential to produce up to 60,000 volts.
- ***Switching device***—mechanical or electronic switch that operates the ignition coil.
- ***Spark plug***—uses high voltage from the ignition coil to produce an arc, igniting the fuel charge.
- ***Ignition system wires***—connect ignition system components.

When the ignition switch is *on* and the switching device is closed (conducting current), current flows through the ignition coil. When the piston is near TDC on its compression stroke, the switching device opens to stop current flow through the ignition coil. This causes the coil to produce a high-voltage surge, which flows through the spark plug wire and arcs across the spark plug's electrodes.

The electric arc, or spark, at the spark plug ignites the fuel mixture. The mixture begins to burn, forming pressure in the cylinder for the engine's power stroke.

When the ignition key is turned to *off*, the battery-to-coil circuit is broken. Without current to the ignition coil, an arc *cannot* be produced at the spark plugs and the engine stops running.

An actual ignition system is much more complex than the one just discussed. Vehicles have multiple-cylinder engines, and the timing of the spark must vary with operating conditions.

Ignition System Supply Voltage

The ***ignition system supply voltage*** is fed to the ignition system by the battery and alternator. On late-model vehicles, these sources feed voltage through the engine control module or the power train control module. The battery provides electricity when starting the engine. After the engine is running, the alternator supplies a slightly higher voltage to the battery and ignition system.

Ignition Switch

The ***ignition switch*** is a key-operated switch in the driver's compartment. A hot wire (voltage supply wire) connects the switch to the battery. Other terminals on the switch are connected to the ignition system, starter solenoid, and other electrical devices.

Bypass and Resistance Circuits

An ignition system ***bypass circuit*** is sometimes used to supply direct battery voltage to the ignition system during starting motor operation. When an engine is being started, the ignition switch is held in the start position (fully clockwise). This connects the battery to the starting motor and to the ignition system, **Figure 35-2A.** The electric motor spins the engine until the engine begins to run.

The starting motor draws high current and causes battery voltage to drop below 12.6 volts. The bypass circuit ensures that there is still enough voltage and current for proper ignition coil operation and easy engine starting.

To protect the ignition system from damage, a ***resistance circuit*** is sometimes placed between the ignition switch and the coil to limit supply voltage to the ignition system during alternator operation. Look at **Figure 35-2B.** After the engine starts, the ignition key switch is released. A spring inside the switch causes it to return to the run position.

Either a special ***resistance wire*** (wire having internal resistance) or a ***ballast resistor*** (heat sensitive resistor that can regulate voltage to the ignition coil) is used in the resistance circuit. This circuit ensures that a relatively steady voltage of about 9.5–10.5 volts is applied to the ignition system. With new vehicles, the ***computer voltage regulator*** supplies current to the ignition circuit.

Tech Tip!

Many electronic and computer controlled ignition systems do *not* use bypass or resistance circuits. Their internal circuitry is capable of controlling voltage and current for optimum ignition system operation.

B

Figure 35-2. Some ignition systems use bypass and resistance circuits to feed current to the ignition coil. A—When cranking, the bypass circuit feeds direct battery voltage to the coil. B—After starting, the resistance circuit feeds controlled voltage to the coil. (Echlin)

Primary and Secondary Circuits

There are two main sections, or circuits, of an ignition system: the primary circuits and secondary circuits. The ***primary circuit*** of the ignition system includes all the components and wires operating on low voltage (battery or alternator voltage). ***Ignition system primary voltage*** is normally below battery voltage (12.6 volts). See **Figure 35-3A.**

The ***secondary circuit*** of the ignition system is the high-voltage section. The ***ignition system secondary operating voltage*** can normally range from 4000–30,000 volts, depending on system design. The secondary consists of the wires and parts between the coil output and the spark plug ground, **Figure 35-3B.**

The primary circuit of the ignition system uses conventional wire, similar to the wire used in the other electrical systems of the car. The secondary wiring, however, must have much *thicker insulation* to prevent ***electrical leakage*** (electricity traveling through insulation or from one component to another).

Ignition Coil

An ***ignition coil*** is a pulse-type transformer that is capable of producing short bursts of high voltage to start combustion. The coil produces a low-current, high-voltage surge that jumps the rotor gap, passes through the secondary resistance wire, and jumps the spark plug gap.

Older vehicles with relatively small spark plug gaps operate at about 4000–8000 volts (4–8 kV). With today's wider spark plug gaps and leaner fuel mixtures, more voltage is needed to make the electricity surge through all the parts of the ignition system. Late-model vehicles operate at about 15,000 volts (15 kV) on average but can

B

Figure 35-3. Two major sections of an ignition system. A—Primary circuit includes all the parts working on battery voltage. B—Secondary circuit consists of all the parts carrying coil output voltage (high voltage). (DaimlerChrysler)

vary from 4000–30,000 volts, depending on ignition system design.

If everything is in good condition, the ignition coil operates below its potential maximum output voltage. This keeps some voltage in reserve. In most late-model systems, the ***ignition coil's open-circuit voltage*** (maximum voltage potential) is 40,000–60,000 volts (40–60 kV).

Ignition Coil Windings

Shown in **Figure 35-4,** the ignition coil consists of two sets of ***windings*** (insulated wire wrapped in circular pattern). It also contains two ***primary terminals*** (low-voltage connections), an ***iron core*** (long piece of iron inside windings), and a ***high-voltage terminal*** (output or coil wire connection).

The ***primary windings*** are made up of several hundred turns of heavy wire wrapped around or near the secondary windings. The ***secondary windings*** consist of several thousand turns of very fine wire located inside or near the primary windings, **Figure 35-5.** Both windings are wrapped around an iron core and are housed inside the coil case.

Ignition Coil Operation

When battery current flows through primary windings of the ignition coil, a strong magnetic field is generated. The action of the iron core helps concentrate and strengthen the field. Look at **Figure 35-6A.**

When the current flowing through the coil's primary windings is interrupted, the magnetic field *collapses*

across the secondary windings. Since the secondary windings have more turns than the primary windings, up to 60,000 volts is induced in the secondary windings. High voltage shoots out of the high-voltage terminal of the coil, traveling through the secondary circuit to a spark plug. See **Figure 35-6B.**

There are two methods used to break current flow and fire the coil: older mechanical breaker points or the more common electronic switching circuit.

Ignition Coil Designs

With today's computer-controlled ignition systems, ignition coils can be more complex than those used in the past. Depending on ignition system design, an engine can have one or more ignition coils. A conventional system has one coil that serves all engine cylinders. A distributorless ignition system has one coil for every two engine cylinders. A direct ignition system has one coil for every engine cylinder.

A ***coil pack*** consists of several ignition coils combined into one assembly, **Figure 35-7.** As you will learn, this type of coil is used in distributorless ignition systems. No coil wire is needed with a coil pack. The spark plug wires are connected from the ignition coil pack to the spark plugs.

Figure 35-8 shows a top view of a coil pack. Note how the secondary connections are numbered so you can connect the right terminal to the correct spark plug. Also note the primary connections.

Figure 35-9. Many coils are wired so they fire two spark plugs simultaneously. One spark plug starts combustion on the power stroke. The other spark plug produces a wasted spark, which occurs during the engine exhaust stroke. Note current flow through the coil, plugs, and ground.

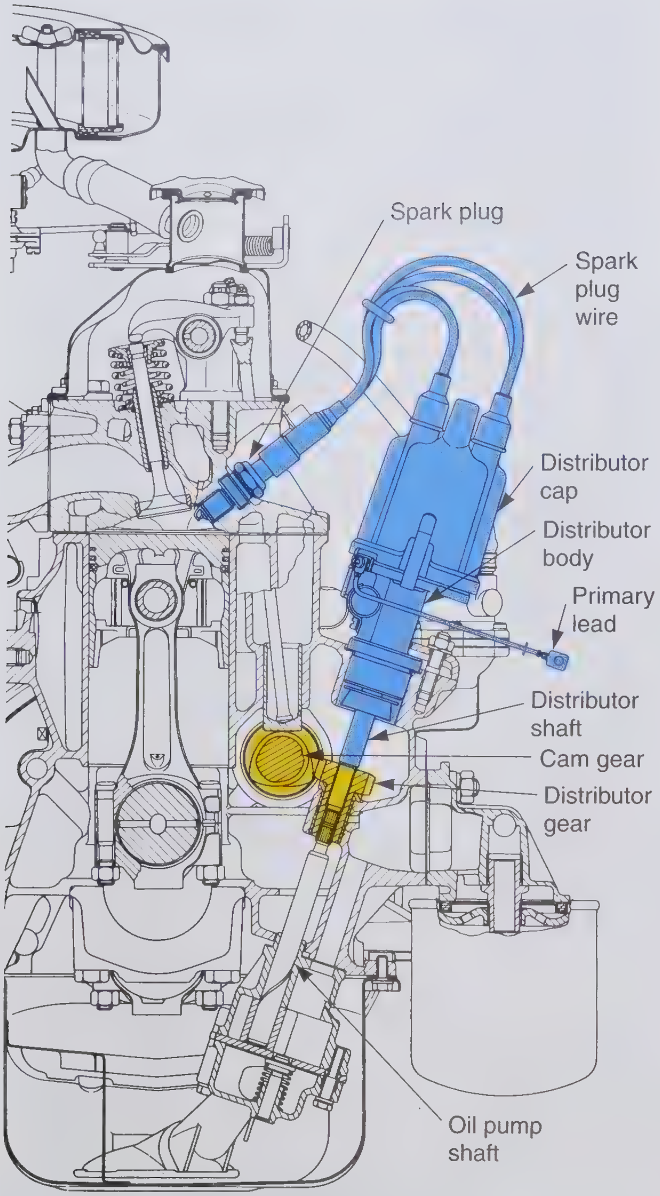

Figure 35-10. The ignition distributor is usually driven by the engine camshaft. A small gear on the cam drives the gear on the distributor at one-half engine rpm. The main purpose of the distributor is to feed coil voltage to the spark plugs. (Fiat)

Wasted-Spark Ignition Coil

A ***wasted-spark ignition coil*** is wired so that it fires two spark plugs at the same time. As illustrated in **Figure 35-9,** each end of the coil's secondary winding is connected to a spark plug wire. Then, when the primary magnetic field collapses across the secondary winding, a high-voltage, low-current surge is induced in both spark plug wires. Current flows across each spark plug gap with the opposite polarity. The engine ground connects the two spark plugs. Wasted-spark coils and distributorless ignition systems will be discussed in more detail later in this chapter.

Ignition Distributors

Typically, an ***ignition distributor,*** **Figure 35-10,** has several functions:

- It actuates the *on/off* cycles of current flow through the ignition coil primary windings.
- It distributes the coil's high-voltage pulses to the spark plug wire.
- It causes the spark to occur at each plug earlier in the compression stroke as engine speed increases and vice versa.
- It changes spark timing with changes in engine load. As more load is placed on the engine, the spark timing must occur later in the compression stroke to prevent spark knock (abnormal combustion).
- Sometimes, the bottom of the distributor shaft powers the engine oil pump.
- Some distributors (unitized distributors) house the ignition coil and electronic switching circuit in one assembly. Refer to **Figure 35-11.**

Distributor Types

An ignition distributor can be a(n):

- Contact point distributor (older, mechanical type).
- Pickup coil distributor (magnetic-sensing coil or winding type).
- Hall-effect distributor (magnetic-sensing, solid-state chip type).
- Optical distributor (LED and light-sensing type).

A contact point distributor is found on older cars. The pickup coil distributor is used on many modern automobiles and is the most common. Hall-effect and optical distributors can be found on a few makes of vehicles.

Distributor Drives

The ***distributor drive*** refers to the method used to rotate the distributor shaft to match engine rpm. On some engines, the ***camshaft gear*** is used to drive the distributor at one-half engine speed. A gear on the bottom of the distributor shaft meshes with the camshaft gear. Anytime the engine camshaft turns, the distributor shaft also turns. See **Figure 35-10.** With this drive arrangement, the distributor can be mounted on the rear of the engine, directly behind the camshaft centerline, or on the front of the engine, under the water pump. Both locations allow ***direct distributor drive*** off the camshaft. This eliminates the problem of backlash, or play, in a distributor drive gear, which can affect ignition timing.

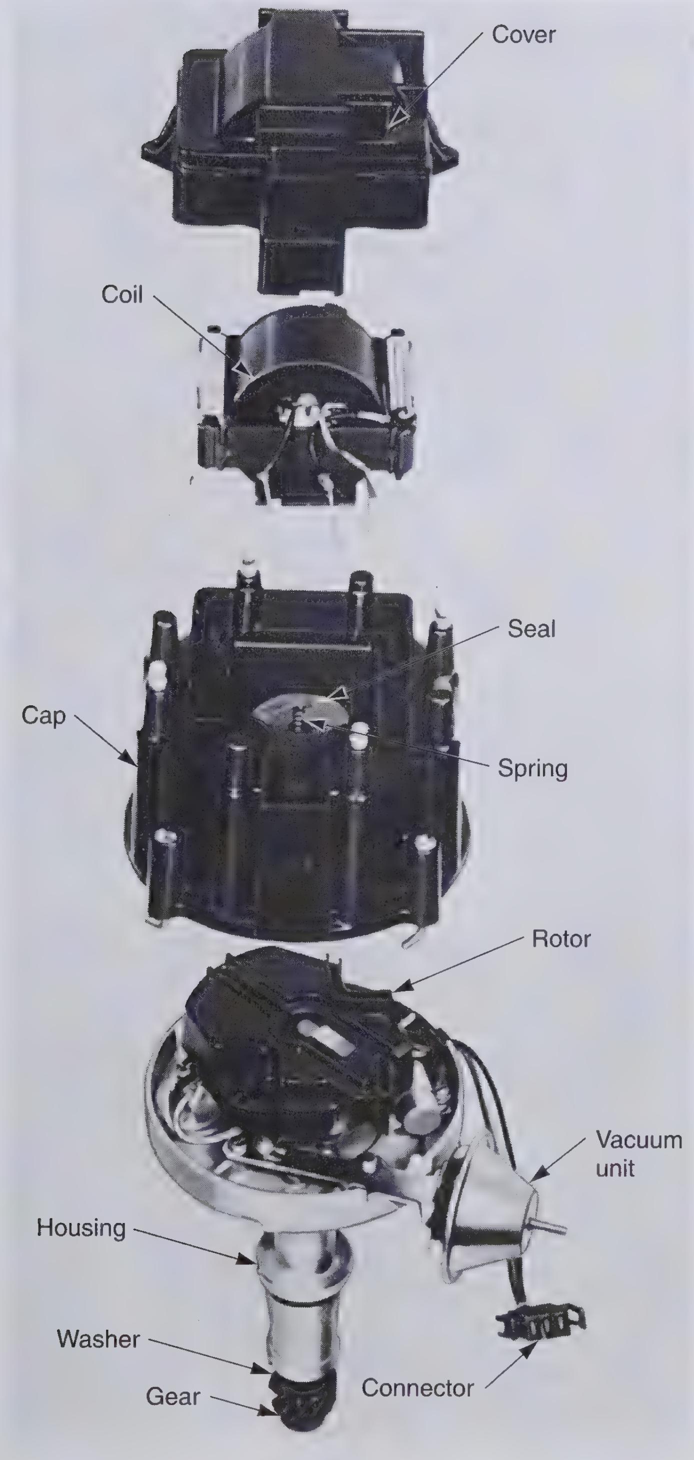

Figure 35-11. Unitized distributor has an ignition coil and an ignition control module (electronic switching circuit) mounted inside its housing. Note the part names and locations. (Chevrolet)

Contact Point Ignition System

Before studying today's electronic ignition systems, you should have a basic understanding of contact point systems. The two systems are similar in many ways, **Figure 35-12.** Also, a contact point system is easier to understand.

The major parts of a contact point distributor include the following:

Distributor cam—Lobed part on the distributor shaft that opens the contact points. The cam turns with the shaft at one-half engine speed. One lobe is normally provided for each spark plug. See **Figure 35-12.**

Contact points (breaker points)—Act like a spring-loaded electrical switch in the distributor. Small screws hold the contact points on the distributor advance plate. A rubbing block of fiber material rides on the distributor cam. Wires from the condenser and ignition coil primary connect to the points.

Condenser (capacitor)—Prevents the contact points from arcing and burning. It also provides a storage place for electricity as the points open. This electricity is fed back into the primary when the points close.

Contact Point Ignition System Operation

With the engine running, the distributor shaft and distributor cam rotate. This causes the cam to open and close the contact points.

Since the points are wired to the primary windings of the ignition coil, the points open and close the ignition coil primary circuit. When the points are closed, a magnetic field builds in the coil. When the points open, the field collapses and voltage is sent to one of the spark plugs.

With the distributor rotating at one-half engine rpm, and with one cam lobe per engine cylinder, each spark plug fires once during a complete revolution of the distributor camshaft.

As you will learn, other distributor and electronic devices are used to determine when the spark plugs fire.

Point Dwell (Cam Angle)

Point dwell, or ***cam angle,*** is the amount of time, given in degrees of distributor rotation, that the points remain closed between each opening, **Figure 35-13.** A dwell period is needed to ensure that the coil has enough time to build up a strong magnetic field.

Without enough point dwell, a weak spark would be produced. With too much dwell, the ***point gap*** (distance between fully open points) would be too narrow. Point arcing and burning could result.

Discussed in the next chapter, modern systems use several methods of controlling dwell electronically. Computer-controlled systems can use fixed dwell, variable dwell, and current-limiting dwell.

Electronic Ignition System

An ***electronic ignition system,*** also called a ***solid-state*** or ***transistor ignition system,*** uses an ignition

control module and a distributor pickup coil to operate the ignition coil. The pickup coil and the module replace the contact points, **Figure 35-14.**

An electronic ignition system is more dependable than a contact point system. There are no mechanical breakers to wear or burn. This helps prevent trouble with ignition timing and dwell.

Figure 35-13. Dwell is the amount of time the points remain closed in degrees of distributor rotation. Point gap is the distance between the two points in the fully open position. Dwell affects point gap and vice versa. With modern electronic systems, the engine control module controls dwell time. (Echlin)

An electronic ignition is also capable of producing much higher secondary voltages than a contact point ignition. This is an advantage because wider spark plug gaps and higher voltages are needed to ignite the lean air-fuel mixtures now used for reduced exhaust emissions and fuel consumption.

Trigger Wheel

The ***trigger wheel,*** also called the ***reluctor*** or ***pole piece,*** is fastened to the upper end of the distributor shaft. See **Figure 35-15.** The trigger wheel replaces the distributor cam used in a contact point distributor. One tooth is normally provided on the wheel for each engine cylinder.

Pickup Coil

The ***pickup coil,*** also called the ***sensor assembly*** or ***sensor coil,*** produces tiny voltage pulses that are sent to the ignition control module. Look at **Figure 35-15.** The pickup coil is a small set of windings that forms a coil.

As a trigger wheel tooth passes the pickup coil, it strengthens the magnetic field around the coil. This causes a change in the current flow through the coil. As a result, an electrical pulse (voltage or current change) is sent to the ignition control module as each trigger wheel tooth passes the pickup unit.

Figure 35-15. Study magnetic pickup coil operation. This principle applies to both distributor pickups and other magnetic coil–type sensors. (DaimlerChrysler)

Hall-Effect Pickup

A ***Hall-effect pickup*** is a solid-state chip or module that produces an electrical signal when triggered by a slotted wheel. A constant amount of current is sent through the device. A permanent magnet is located next to the Hall-effect chip. See **Figure 35-16.**

When the slotted wheel's tab passes between the permanent magnet and the Hall-effect chip, the magnetic field is blocked, decreasing the chip's output voltage (sensor or switch *off*). When the slotted wheel's tab moves out from between the magnet and chip, magnetic field action increases the chip's voltage output (sensor or switch *on*). This *on/off* action operates the ignition control module.

Optical Pickup

An ***optical pickup*** uses ***LEDs*** (light-emitting diodes) and ***photo diodes*** (light sensors) to produce an engine speed signal for the ignition system. As shown in **Figure 35-17,** a slotted rotor plate rotates between the light-emitting diodes and the photo diodes. When a slot, or window, passes between the two diodes, light from the LEDs strikes the photo diodes and an electrical signal is generated.

An optical pickup is seldom used because its operation is adversely affected by a dirt buildup on the LEDs and photo diodes.

Ignition Control Module

The ***ignition control module,*** or ***electronic control unit amplifier,*** is an "electronic switch" that turns the

ignition coil primary current on and off. The module does the same thing as contact points. See **Figure 35-18.**

An ignition control module is a network of transistors, resistors, capacitors, and other electronic components. The circuit is sealed in a plastic or metal housing. A typical module and related components are shown in **Figure 35-19.** The ignition control module can be located in the engine compartment, on the side of the distributor, inside the distributor, or under the vehicle's dash. See **Figure 35-20.**

Electronic Ignition System Operation

With the engine running, the trigger wheel spins inside the distributor. As the teeth pass the pickup, a change in the magnetic field causes a change in output voltage or current. This output voltage, which represents engine rpm, is sent to the ignition control module, **Figure 35-19.**

The ignition control module increases these tiny pulses into *on/off* current cycles for the ignition coil. When the module is *on*, current flows through the primary windings of the ignition coil, developing a magnetic field. Then, when the trigger wheel and pickup turn *off* the module, the ignition coil field collapses and fires a spark plug.

Dwell time (number of degrees of camshaft rotation that the circuit conducts current to the ignition coil) is designed into the ignition control module's electronic circuit. It is not adjustable.

Distributor Cap and Rotor

The ***distributor cap*** transfers high voltage from the rotor to the spark plug wires. It is an insulating plastic

B—Just as trigger wheel passes pickup coil, current pulse flows out of pickup and to base of transistor. Electrical pulse is opposite the polarity of emitter-base voltage. This turns transistor off. Without current flow through emitter and collector, field collapses in ignition coil and 30,000 volts is induced into coil secondary windings. Spark plug fires.

component that fits over the top of the distributor housing. Metal terminals are molded into the plastic cap to make electrical connections. The cap's center terminal is connected to the coil wire, **Figure 35-21**. Its outer terminals, or side terminals, are connected to the spark plug wires.

The ***rotor*** transfers voltage from the distributor cap's center terminal to its outer terminals The rotor is mounted on top of the distributor shaft. It is a spinning electrical switch that feeds voltage to each spark plug wire in turn. Look at **Figure 35-21**.

A metal terminal on the rotor touches the center terminal of the distributor cap. The outer end of the rotor terminal *almost* touches the outer cap terminals.

(Bosch, Ford, DaimlerChrysler)

Secondary voltage is high enough that it can jump the air gap, or space, between the rotor and the outer terminals. About 2000–6000 volts is needed for the spark to jump the rotor-to-cap gap in today's ignition systems.

Engine ground
Rotor
Distributor cap
Ignition coil

Figure 35-21. With a distributor, ignition coil output is fed through the coil wire to the distributor cap center terminal. The spinning rotor then feeds high voltage to each spark plug wire. (Echlin)

Secondary Wires

Secondary wires carry the high voltage produced by the ignition coil. The ***coil wire*** carries voltage from the high-voltage (high-tension) terminal of the ignition coil to the distributor cap, **Figure 35-21.** ***Spark plug wires*** carry coil voltage from the side terminals of the distributor cap to the spark plugs. See **Figure 35-22.**

Tech Tip!
With a unitized distributor or distributorless ignition, a coil wire is *not* needed. Secondary wires carry high voltage from the ignition coil directly to the spark plugs. With a direct ignition system, explained shortly, no secondary spark plug wires are needed.

Solid secondary wires are used on racing engines and very old automobiles. The wire conductor is simply a stranded metal wire. Solid secondary wires are no longer used because they cause radio interference (noise or static in stereo speakers, CB radios, etc.).

Resistance wires are now used because they contain internal resistance, which helps prevent radio noise. They consist of carbon-impregnated strands and rayon braids. Look at **Figure 35-23.** Also called ***radio suppression wires,*** resistance wires have about 10,000 ohms of resistance per foot.

Insulated ***boots*** usually fit over both ends of the secondary wires to protect the metal connectors from corrosion, oil, and moisture.

Figure 35-22. Secondary wires transfer high voltage between the ignition system components. Clips secure the wires so they do not get burned by hot exhaust manifolds or induce voltage into the computer system wires. (Chevrolet)

Spark Plugs

The ***spark plugs*** use ignition coil high voltage to ignite the fuel mixture. A secondary voltage between 4000 and 28,000 volts is needed to make current jump the gap at the spark plug electrodes. This is much lower than the coil's output voltage potential discussed earlier.

As shown in **Figure 35-24,** the basic parts of a spark plug include the:

- ***Center terminal (center electrode)***—Conducts electricity into the combustion chamber.
- ***Grounded side electrode***—Causes the electricity to jump the gap and return to the battery through frame ground.
- ***Ceramic Insulator***—Keeps the high voltage at the plug wire from shorting to ground before producing a spark in the engine cylinder.
- ***Steel shell***—Supports the other parts of the plug and has threads for screwing the plug into the engine cylinder head.

Center electrode

Figure 35-24. Note spark plug variations. Small 14 mm plugs are commonly used in today's engines. Larger 18 mm plugs are for older engines. Spark plug reach is the length of the plug threads. (DaimlerChrysler)

Spark Plug Reach

Spark plug reach is the distance between the end of the plug threads and the seat or sealing surface on the plug shell. Refer to **Figure 35-24.** Plug reach determines how far the plug extends through the cylinder head.

If spark plug reach is too long, the plug electrode may be struck by the piston at TDC. If reach is too short, the plug electrodes may not extend far enough into the chamber and combustion efficiency may be reduced.

Resistor and Non-Resistor Spark Plugs

A ***resistor spark plug,*** like a resistor plug wire, has internal resistance (around 10,000 ohms) designed to reduce static in radios and television sets. Most newer vehicles require resistor plugs.

A ***non-resistor spark plug*** has a solid metal rod forming the center electrode. This type of plug is *not* commonly used, but it is found in some racing and off-road applications. **Figure 35-25** illustrates both resistor and non-resistor spark plugs.

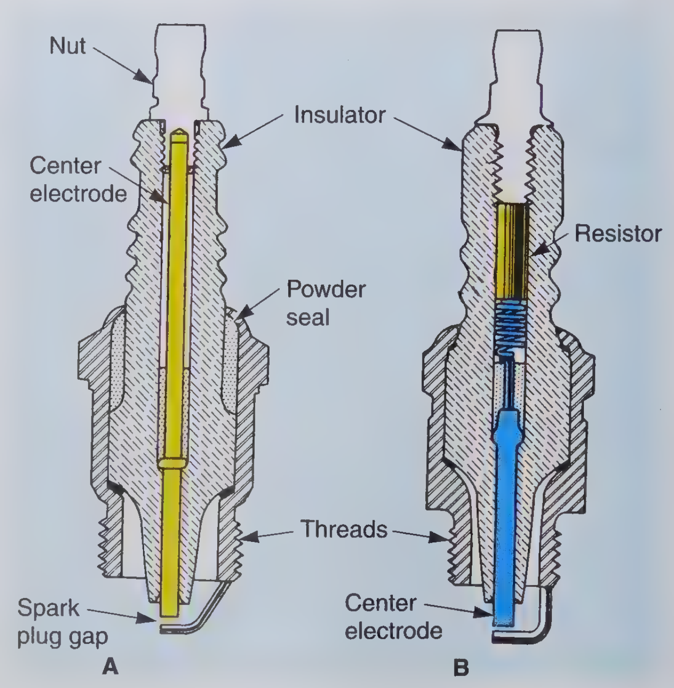
Spark Plug Gap

Spark plug gap is the distance between the center and side electrodes, **Figure 35-25.** Normal gap specifications range from 0.030″–0.080″ (0.76 mm–2.0 mm).

Smaller spark plug gaps are used on older cars. Larger spark plug gaps are used with electronic and computerized ignition systems.

Spark Plug Heat Range

Spark plug heat range is a rating of the operating temperature of the spark plug tip. Plug heat range is



Nut

Center electrode
A
B

Figure 35-25. Cutaway shows the internal parts of a plug. A—Non-resistor plug has a solid metal center electrode. B—Resistor plug has a small resistor between the two-piece center electrode. Plug gap is the space between the side and center electrodes. (Ethyl Corp.)

basically determined by the length and diameter of the insulator tip and the ability of the plug to transfer heat into the cooling system. Refer to **Figure 35-26.**

A ***hot spark plug*** has a long insulator tip and will tend to burn off deposits. This provides a self-cleaning action.

A ***cold spark plug*** has a shorter insulator tip; its tip operates at a cooler temperature. A cold plug is used in engines operated at high speeds. The cooler tip will help prevent tip overheating and preignition.

Heat Range Ratings

Auto manufacturers normally recommend a specific spark plug heat range for their engines. The heat range will normally be coded and given as a number on the plug insulator. Generally, the larger the number on the plug, the hotter the spark plug tip will operate. For instance, a 52 plug would be hotter than a 42.

The only time you should deviate from plug heat range specifications is when abnormal engine or driving conditions are encountered. For example, a hotter plug may be installed in a worn out, oil-burning engine. The hotter plug will help burn off oil deposits. This will prevent spark plug oil fouling.

Dual Spark Plug Ignition System

A few engines have a ***dual spark plug ignition system.*** In these systems, two spark plugs are used in each cylinder. For instance, a four-cylinder engine would use eight spark plugs. With this design, one ignition coil can be used to fire both plugs at the same time. The coil configuration used in this type of system is similar to the coil arrangement used in a waste spark system.

One spark plug is located near the intake valve and the other near the exhaust valve. Dual plugs help ensure better ignition and more complete combustion of the air-fuel mixture.

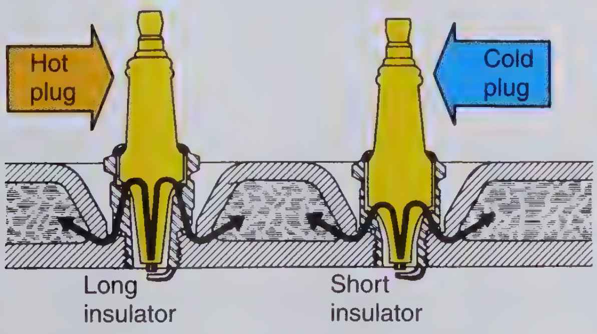

Figure 35-26. A hot plug has a long insulator that prevents heat transfer into the water jackets. It will burn off oil deposits. A cold plug has a shorter insulator. (Ethyl Corp.)

Multiple Discharge Ignition System

A multiple discharge ignition system fires the spark plugs more than once on each power stroke. By producing a series of sparks, it helps ensure more complete burning of the fuel charge. This type of ignition is commonly used on racing engines.

Ignition Timing

Ignition timing, also called ***spark timing,*** refers to how early or late the spark plugs fire in relation to the position of the engine pistons. Ignition timing must change with changes in engine speed, load, and temperature.

Timing advance occurs when the spark plugs fire sooner on the engine's compression strokes. The timing is set several degrees before top dead center (BTDC). Even more timing advance is needed at higher engine speeds to give combustion enough time to develop pressure on the power stroke. See **Figure 35-27.**

Timing retard occurs when the spark plugs fire later on the compression strokes. It is the opposite of timing advance. Timing retard is needed at lower engine speeds and under high load conditions. Timing retard prevents the fuel from burning too much on the compression stroke, causing a spark knock or ping (abnormal combustion).

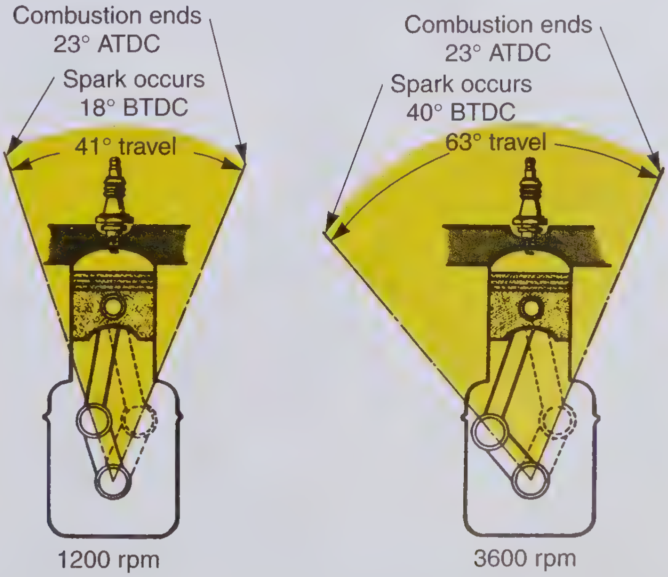

Figure 35-27. Since each combustion period takes about the same amount of time, the spark must start combustion sooner as engine speed increases. This will ensure that all the fuel is burned on the power stroke and that sufficient pressure acts upon the piston. (Sun Electric Corp.)

There are three basic methods used to control ignition system spark timing:

- ***Distributor centrifugal advance***—Controlled by engine speed, **Figure 35-28.**
- ***Distributor vacuum advance***—Controlled by engine intake manifold vacuum and engine load, **Figure 35-28.**
- ***Electronic advance***—Controlled by a computer.

Distributor Centrifugal Advance

The ***distributor centrifugal advance*** makes the ignition coil and spark plugs fire sooner as engine speed increases. It uses spring-loaded weights, centrifugal force, and lever action to rotate the distributor cam or trigger wheel on the distributor shaft. By rotating the cam or trigger wheel against distributor shaft rotation, spark timing is advanced. Centrifugal advance helps maintain correct ignition timing for maximum engine power. See **Figure 35-29.**

Pole piece
Housing
Vacuum advance diaphragm

Figure 35-28. Study the parts of vacuum and centrifugal advance mechanisms. (Robert Bosch)

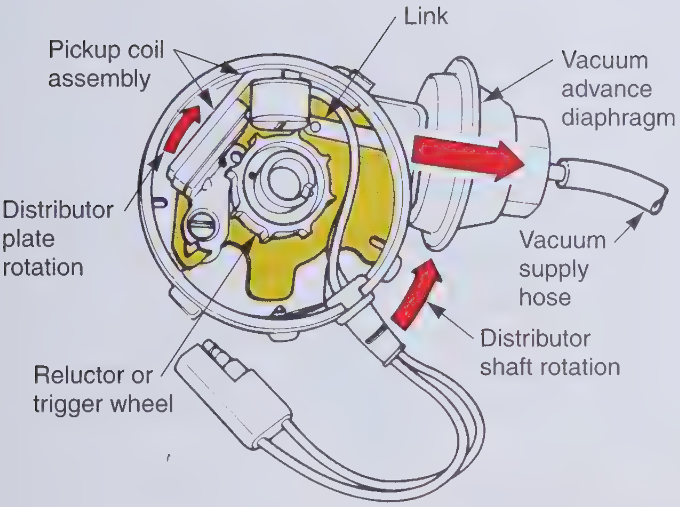
At low engine speeds, small springs hold the advance weights inward to keep timing retarded. As engine speed increases, centrifugal force overcomes spring tension. The weights are thrown outward, and they act on the cam or trigger wheel lever. This rotates the distributor cam or trigger wheel. As a result, the points open sooner or the trigger wheel and pickup coil turn off the ignition control module sooner. This causes the ignition coil to fire with the engine pistons farther down in their cylinders.

As engine speed keeps increasing, the weights swing out farther and timing is advanced a greater amount. At a preset engine rpm, the lever strikes a stop, preventing the centrifugal advance mechanism from further advancing the ignition timing.

Distributor Vacuum Advance

The ***distributor vacuum advance*** provides additional spark advance at part (medium) throttle positions when the engine load is low. It is a method of matching ignition timing to *engine load.* The vacuum advance mechanism increases fuel economy because it helps maintain ideal spark advance at all times.

A distributor vacuum advance mechanism consists of a vacuum advance diaphragm, a link, a movable distributor plate, and a vacuum supply hose. Look at **Figure 35-30.**



Link
Pickup coil assembly
Vacuum advance diaphragm
Distributor plate rotation
Vacuum supply hose
Distributor shaft rotation
Reluctor or trigger wheel

Figure 35-30. Vacuum advance uses a vacuum advance diaphragm to rotate the pickup coil or contact points against the direction of distributor shaft rotation. (DaimlerChrysler)

At idle, the vacuum port to the distributor advance is covered. Vacuum (suction) is *not* applied to the vacuum diaphragm. Spark timing is *not* advanced.

At part throttle, the throttle valve uncovers the vacuum port and the port is exposed to engine vacuum. This causes the distributor diaphragm to be pulled toward the vacuum. The distributor plate (points or pickup coil) is rotated against distributor shaft rotation and spark timing is advanced.

During acceleration and full throttle, engine vacuum drops. Thus, vacuum is *not* applied to the distributor diaphragm and the vacuum advance does *not* operate.

A ***dual-diaphragm vacuum advance,*** which was used on some distributors to aid early emission-control systems, contains two separate vacuum chambers: an advance chamber and a retard chamber.

A ***vacuum delay valve*** restricts the flow of air to slow down the vacuum action on a vacuum device. It keeps the vacuum advance from working too quickly, preventing possible knock or ping. The vacuum delay valve is usually located in the vacuum line going to the distributor diaphragm. A check valve allows the free release of vacuum from the diaphragm when returning to the retard position.

Electronic (Computer) Spark Advance

An ***electronic spark advance system,*** or ***computer-controlled spark advance system,*** uses engine sensors, an ignition control module, and/or a computer (engine control module or power train control module) to adjust ignition timing. A distributor may or may not be used in this type of system. If a distributor is used, it will *not* contain centrifugal or vacuum advance mechanisms. **Figure 35-31**

shows a block diagram of how information is used to control engine ignition timing electronically.

The ***engine sensors*** check various operating conditions and send electrical data representing these conditions to the computer. The computer can then analyze the data and change ignition timing for maximum engine efficiency.

Sensors that influence ignition timing include:

- ***Crankshaft position sensor***—Reports engine rpm to the computer.
- ***Camshaft position sensor***—Tells the computer which cylinder is on its power stroke.
- ***Manifold absolute pressure sensor***—Measures engine intake manifold vacuum, an indicator of load.
- ***Intake air temperature sensor***—Checks temperature of air entering the engine.
- ***Engine coolant temperature sensor***—Measures the operating temperature of the engine.
- ***Knock sensor***—Allows the computer to retard timing when the engine pings or knocks.
- ***Throttle position sensor***—Notes the position of the throttle.

The computer receives input signals (different current or voltage levels) from these sensors. It is programmed (preset) to adjust ignition timing to meet different engine conditions. The computer may be mounted on the air cleaner, on the fender inner panel, under the dash, or under a seat.

The computer can also measure battery voltage to compensate for voltage variations due to battery state of charge, accessory loads, etc.

Electronic Spark Advance Operation

For an example of electronic spark advance, imagine a car or light truck traveling down the highway at 55 mph (88 km/h). The crankshaft sensor would detect moderate engine rpm. The throttle position sensor would detect part throttle. The intake air and coolant temperature sensors would report normal operating temperatures. The manifold absolute pressure sensor would send high vacuum signals to the computer.

The computer could then calculate that the engine would need almost maximum spark advance. The timing would occur several degrees before TDC on the compression stroke. This would ensure that the engine attained high fuel economy on the highway. There would be enough time for all the fuel to burn and produce maximum pressure on the downward motion of the pistons.

If the driver began to pass a car, engine intake manifold vacuum would drop to a very low level. The manifold absolute pressure sensor signal would be fed to the computer. The throttle position sensor would detect wide open throttle (WOT). Other sensor outputs would stay about the same. Based on the signals from the manifold absolute pressure sensor and the throttle position sensor, the computer could then retard ignition timing to prevent spark knock or ping.

Since computer systems vary, refer to a service manual for more information. The manual will detail the operation of the specific system for that make and model vehicle.

Base Timing

Most new cars use the computer to control ignition timing advance. To check timing, you may have to trigger the computer to go to base timing. ***Base timing*** is the ignition timing without computer-controlled advance. This will be explained in more detail in the next chapter.

Crankshaft-Triggered Ignition

A ***crankshaft-triggered ignition*** can maintain more precise ignition timing than a system with a distributor-mounted pickup coil. There is no backlash or play in the distributor drive gear, timing chain, or gears to upset ignition timing. Crankshaft and piston position is "read" right off the crankshaft. **Figure 35-32** shows a simplified illustration of a crankshaft-triggered ignition.

A ***crankshaft trigger wheel,*** also called the ***pulse ring*** or ***reluctor ring,*** is mounted on the crankshaft damper or the crankshaft itself to provide engine speed and crankshaft position data for the sensors and computer. In some cases, the wheel is cast or machined as an integral part of the shaft. The crankshaft trigger wheel performs the same function as the trigger wheel used in the distributor for an electronic ignition. The teeth on the trigger wheel correspond to the number of engine cylinders and position of the crank journals (pistons), **Figure 35-33.**

The ***crankshaft position sensor*** is mounted next to the crankshaft trigger wheel and sends electrical pulses to the system computer. It does the same thing as a distributor pickup, **Figure 35-33.**

If used, the distributor for a crankshaft-triggered ignition simply transfers high voltage to each spark plug wire through a spinning rotor and a stationary cap. No advance mechanisms, pickup coil, or related parts are inside the distributor in a crankshaft-triggered ignition system.

Figure 35-32. This simplified crankshaft-triggered ignition system places the pickup coil or coils next to the engine crankshaft damper. Teeth on the damper act as a trigger wheel to send electrical pulses to the computer. The computer can then operate the ignition coil and control spark advance or retard. Study the parts and wiring. (Robert Bosch)

Crankshaft-Triggered Ignition Operation

The operation of a crankshaft-triggered ignition is similar to that of the electronic systems already covered. Some designs use one crankshaft position sensor; others use two.

Figure 35-34 shows a crankshaft-triggered ignition system that uses two crankshaft position sensors. Both sensors extend through the cylinder block and are sealed with rubber O-rings. Other engines can have the crankshaft position sensor mounted on the front of the engine in a small bracket.

As the crankshaft spins, the crankshaft trigger wheel and the crankshaft position sensor or sensors produce *on-off-on-off* voltage signals representing crankshaft speed and position. Depending on design, a different number of teeth can be used on the crankshaft trigger wheel. Some of the teeth are offset so that the sensors can detect crankshaft position.

A camshaft position sensor and a knock sensor can also be used to feed data to the engine control module. The ***camshaft position sensor*** provides information on camshaft and valve position. The ***knock sensor*** monitors preignition or knock so the computer can retard timing or reduce turbocharger boost pressure as necessary, **Figure 35-34.**

Figure 35-34. Newer ignition system designs do not use a distributor. The on-board computer and an electronic coil control module operate multiple ignition coils. A crankshaft position sensor and a camshaft position sensor send electrical signals to help determine the time when the coils fire. Trace the connections from each component. (General Motors)

Figure 35-35 shows a close-up of a crankshaft trigger wheel and a crankshaft position sensor. Note how the sensor mounts through the engine block. Also note the spacing of the notches on the trigger wheel.

Tech Tip!
Most crankshaft trigger wheels are missing one tooth (or irregularly spaced teeth). The missing tooth represents top dead center or a reference for measuring crankshaft position.

Distributorless Ignition System

A ***distributorless ignition system***, also called a ***computer-coil ignition***, uses multiple ignition coils, a coil control unit, engine sensors, and a computer (engine control module) to operate the spark plugs. A distributor is *not* needed in this type of system. See **Figure 35-34**.

An ***electronic coil module*** consists of two or more ignition coils and a coil control unit (electronic circuit) that operates the coils. Each coil in the coil module serves two cylinders. Therefore, a four-cylinder engine would have a coil module with two ignition coils. A six-cylinder engine, on the other hand, would need a coil module with three ignition coils.

The coil control unit performs about the same function as the ignition control module in an electronic ignition. It is more complex, however, because it must analyze data from engine sensors and the engine control module.

The coils in a distributorless ignition system are wired so they fire *two spark plugs* at once. One spark plug fires during its cylinder's power stroke. The other plug fires during its cylinder's exhaust stroke, so its spark has no effect on engine operation.

A camshaft position sensor sends electrical pulses to the coil control unit, providing data on camshaft and valve position. The crankshaft position sensor feeds pulses to the control unit that show engine speed and piston position. A knock sensor may be used to allow the system to retard timing if the engine begins to ping or knock.

Distributorless Ignition System Operation

Figure 35-36 illustrates how a distributorless ignition system works. The on-board computer monitors engine-operating conditions and controls ignition timing. Some sensor data is also fed to the coil control unit.

When the computer and sensors (including the crankshaft position sensor) send correct electrical pulses to the coil control unit, the control unit fires one of the ignition coils.

Since each coil secondary output is wired to two spark plugs, both plugs fire. One spark plug arc produces the power stroke. The other arc does nothing (wasted spark explained earlier) because its cylinder is on the exhaust stroke: burned gases are simply being pushed out of the cylinder.

When prompted by the computer and sensors, the coil control units fires the next ignition coil. Another two spark plugs arc, producing one more power stroke. This process is repeated over and over as the engine runs.

Advantages of a Distributorless Ignition

A distributorless ignition system has several possible advantages over other ignition types. Some of these include:

- No rotor or distributor cap to burn, crack, or fail.
- Computer-controlled spark advance. No mechanical weights to stick or wear. No vacuum advance diaphragm to rupture or leak.
- Play in timing chain and distributor drive gear is eliminated as a problem that could upset ignition timing. The crankshaft position sensor is not affected by timing chain slack or gear play.

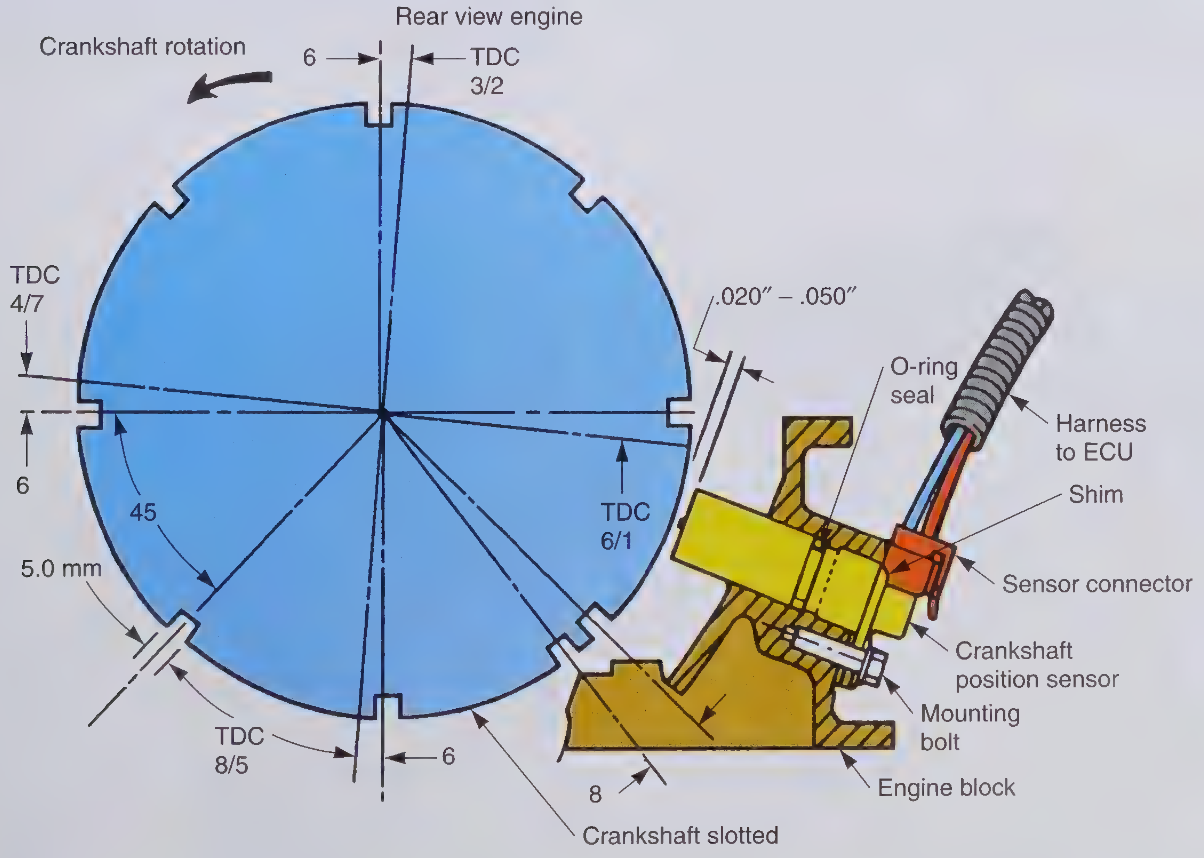

Figure 35-35. This crankshaft trigger wheel is cast and machined as an integral part of the crankshaft. Note how the crankshaft position sensor fits through the cylinder block. A rubber O-ring seal prevents oil leakage. An offset notch on the wheel allows the computer to detect crankshaft position, as well as speed.

Figure 35-36. This simplified illustration shows the operation of an ignition system that does not use a distributor. Inputs to the coil control unit include signals from the crankshaft position sensor, the camshaft position sensor, and the computer. With the correct inputs, the control unit fires one of the ignition coils, which, in turn, fires two spark plugs. One plug produces a power stroke. The other plug sparks as burned exhaust leaves the cylinder. Two coils would operate the ignition for a four-cylinder engine. Three coils would be needed for a six-cylinder engine.

Spark plug

Figure 35-38. Engine cutaway shows a coil mounted over a spark plug.

- There are fewer moving parts to wear and malfunction. See **Figure 35-37.**
- Requires less maintenance. Ignition timing is usually *not* adjustable.

Direct Ignition System

In a ***direct ignition system***, one coil assembly is mounted directly above each spark plug, **Figure 35-38.** This eliminates the need for spark plug wires. It also allows the use of smaller ignition coils. The other components in a direct ignition system (computer, sensors, etc.) are the same as those used in a distributorless system.

The direct ignition coils fire only on the power strokes. They do not fire on the exhaust strokes like wasted spark ignition systems. **Figure 35-39** shows a cutaway of the direct ignition coils for a four-cylinder engine.

There is some confusion in the industry about the terms *distributorless ignition* and *direct ignition*. A distributorless ignition system may or may not use spark plug wires, but it will have some form of conductor between the coils and spark plugs. A direct ignition system mounts one ignition coil over the top of each spark plug without a spark plug wire. Some technicians mistakenly call a distributorless ignition a direct ignition system when high-voltage output is not directly fed to each spark plug.

Coil fires
Coils do not fire

Figure 35-39. Cutaway of an ignition coil for a direct ignition system. With four-cylinder engine, four coils would be needed. (Saab)

Tech Tip!

In some multi-coil ignition systems, the engine control computer measures the time needed to charge each ignition coil. Charge time varies with each coil's resistance/inductance and with the output voltage from the alternator. The computer uses this charge time to determine the ignition coil on-time for optimum spark plug arc duration and spark timing.

Ionization Knock Sensing

In some cases, an ***ionization knock sensing*** system is used to detect abnormal combustion and knocking. In these systems, the computer prompts the ignition coil to send a low-voltage discharge across the spark plug gap immediately following combustion. The quality of combustion affects the resistance across the plug gap by varying the degree of ionization (the process by which atoms gain or lose electrons) in the gases between the plug's electrodes. Consequently, the quality of combustion influences the strength of the discharge across the gap. The computer uses feedback from the discharge to determine if the spark advance or the turbocharger boost should be modified to reduce knocking. A conventional knock sensor is not needed in an ionization knock sensing system.

Engine Firing Order

Engine firing order refers to the sequence in which the spark plugs fire to cause combustion in each cylinder. A four-cylinder engine may have one of two firing orders: 1-3-4-2 or 1-2-4-3. The cylinders are numbered 1-2-3-4, starting at the front of the engine. In this way, you can tell which cylinders will fire in sequence. Firing orders and cylinder numbers for V-6 and V-8 engines vary. **Figure 35-40** shows typical firing orders for 4-, 6-, and 8-cylinder engines.

The engine firing order is sometimes cast into the top of the intake manifold. When not on the manifold, the firing order can be found in a service manual. See **Figure 35-41.**

Discussed in later chapters, the engine firing order is commonly used when installing spark plug wires and when doing other tune-up tasks.

Industry Trend

Spark plugs are available in two basic varieties: standard plugs and premium plugs. The electrodes in standard plugs are generally made of a nickel-chrome alloy. These electrodes are subject to erosion caused by the high-voltage arc across the spark plug gap. Therefore, most manufacturers recommend replacing standard spark plugs every 30,000–45,000 miles.

Premium spark plugs, on the other hand, have precious metal (platinum, iridium, gold palladium, etc.) electrodes. These electrodes are much more durable than those found on standard plugs. Most premium plugs have recommended replacement intervals of 100,000 miles.

Summary

- The vehicle's ignition system produces the high voltage needed to ignite the fuel charges in the cylinders of a spark ignition engine.

- The ignition switch is a key-operated switch in the driver's compartment.
- The primary circuit of the ignition system includes all the components and wires operating on low voltage (battery or alternator voltage).
- The secondary circuit of the ignition system is the high-voltage section.
- The ignition system secondary operating voltage can normally range from 4000–30,000 volts, depending upon system design.
- An ignition coil produces the high voltage (between 4000 and 30,000 volts under normal operating conditions) needed to make high voltage, low current flow through the system.
- The trigger wheel, also called reluctor or pole piece, is fastened to the upper end of the distributor shaft.
- The ignition control module is an "electronic switch" that turns the ignition coil primary current on and off.
- The distributor cap is an insulating plastic component that fits over the top of the distributor housing. Its center terminal transfers voltage from the coil wire to the rotor.
- Spark plug wires carry coil voltage from the distributor cap side terminals to each spark plug.
- The spark plugs use ignition coil high voltage to ignite the fuel mixture.
- Ignition timing, also called spark timing, refers to how early or late the spark plugs fire in relation to the position of the engine pistons.
- A crank-triggered ignition can maintain more precise ignition timing than a system with a distributor-mounted pickup coil.
- A distributorless ignition system uses multiple ignition coils, a coil pack, a coil control unit, engine sensors, and a computer (engine control module) to operate the spark plugs.
- A direct ignition system has an ignition coil mounted over the top of each spark plug.

Review Questions—Chapter 35

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What are the six basic functions of an ignition system?
2. List and explain the six major parts of an ignition system.
3. An ignition system _____ circuit is used to supply direct battery voltage to the system during starting motor operation.
4. Define the terms "primary circuit" and "secondary circuit."
5. An ignition coil is capable of producing an open-circuit voltage of:
   (A) 70–90 kV.
   (B) 80–100 kV.
   (C) 40–60 kV.
   (D) None of the above.
6. The primary windings of an ignition coil are several hundred turns of heavy wire. True or False?
7. When the current flowing through the ignition coil is broken, the magnetic field _____ and induces high _____ into the secondary.
8. Explain the differences between a contact point distributor and a pickup coil (electronic) distributor.
9. What is dwell?
10. An electronic ignition system uses a distributor pickup coil and an ignition control module to operate the _____ _____.
11. How does the pickup coil produce signals for the ignition control module?
12. The ignition control module is *not* normally located in the distributor. True or False?
13. Dwell time is not _____ in an electronic ignition system.
14. What is electrical leakage?
15. The _____ _____ is an insulating plastic component that fits over the distributor housing and sends voltage to each spark plug wire.
16. Explain the function of the distributor rotor.
17. Why do spark plug wires need internal resistance?
18. It normally takes about _____ to _____ volts to operate a spark plug.
19. Spark plug gap is the distance between the center electrode and side electrode. True or False?
20. A cold spark plug might be beneficial in an older engine that burns some oil. True or False? Explain.
21. Describe the difference between timing advance and timing retard.

22. List and explain the three methods of controlling ignition timing.
23. The distributor centrifugal advance depends upon engine _____ and the vacuum advance depends upon intake manifold pressure (vacuum), an indicator of engine _____.
24. Electronic spark advance uses engine _____ and a(n) _____ _____ _____ to control ignition timing.
25. How does a crankshaft-triggered electronic ignition system work?
26. Which of the following does *not* relate to a distributorless ignition system?
    (A) No rotor.
    (B) No centrifugal or vacuum advance.
    (C) Two cylinders per ignition coil.
    (D) No spark plug wires.
27. With a distributorless ignition, two spark plugs fire at once. True or False?
28. List five possible advantages of a distributorless ignition.
29. What is a direct ignition system?
30. Engine _____ _____ refers to the sequence in which the spark plugs operate to cause combustion in each cylinder.

ASE-Type Questions

1. An ignition system uses this to change battery voltage into high secondary voltage:
    (A) spark plug.
    (B) bypass circuit.
    (C) coil.
    (D) ballast resistor.
2. Which of the following provides voltage to the battery and ignition system *after* an engine is running?
    (A) Alternator.
    (B) Condenser.
    (C) Primary circuit.
    (D) Secondary circuit.
    (E) None of the above.
3. Ignition system wires operating at battery voltage are considered part of the:
    (A) ignition coil.
    (B) primary circuit.
    (C) secondary circuit.
    (D) primary windings.
4. Technician A says that with modern ignition coils, open-circuit voltage can reach 60 kV. Technician B says that average operating voltages for an ignition system are about 15 kV. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
5. Which of the following is *not* a possible function of the ignition distributor?
    (A) House the ignition coil.
    (B) Power the engine oil pump.
    (C) Transfer high voltage to the coil.
    (D) Distribute coil pulses to each plug wire.
6. Technician A says an older contact point system produced more secondary voltage than modern electronic or computer controlled systems. Technician B says a contact point system was also more dependable than modern systems. Who is right?
    (A) A only.
    (B) B only.
    (C) Both A and B.
    (D) Neither A nor B.
7. An ignition control module can be located at each of these spots *except:*
    (A) in the vehicle's trunk.
    (B) inside the distributor.
    (C) under the vehicle dash.
    (D) in the engine compartment.
8. Which of the following spark plug components causes electricity to jump the gap and return to the battery through frame ground?
    (A) Shell.
    (B) Insulator.
    (C) Side electrode.
    (D) Center terminal.
9. Which of the following is *not* a typical electronic spark advance ignition system sensor?
    (A) Vehicle speed sensor.
    (B) Knock sensor.
    (C) Manifold absolute pressure sensor.
    (D) Crankshaft position sensor.
10. A direct ignition system uses:
    (A) spark plug wires.
    (B) secondary conductors strips.
    (C) one coil per spark plug.
    (D) All of the above.

Activities—Chapter 35

1. If you have access to a computer with a CAD or drawing program, use it to make a cross-sectional drawing of a resistor-type spark plug. Label the components, then output the drawing to a printer, if available.
2. Make a list of the various engine sensors used with an electronic spark advance system. Describe the purpose of each sensor.
3. Using shop manuals, identify the firing order of the spark plugs for two different makes of four–, six–, and eight–cylinder engines.
4. Make a wall chart comparing contact point, electronic, distributorless, and direct ignition system types.

36

Ignition System Problems, Testing, and Repair

After studying this chapter, you will be able to:

- Diagnose typical ignition system problems.
- List the symptoms produced by faulty ignition system components.
- Describe common tests used to find ignition system troubles.
- Explain how to replace or repair ignition system parts.
- Summarize contact point and pickup coil adjustments.
- Adjust ignition timing.
- Describe safety practices to follow when testing or repairing an ignition system.
- Correctly answer ASE certification test questions on the diagnosis and repair of ignition systems.

An ignition system is one of the most important systems on a gasoline-powered engine. If a problem exists in the ignition, engine performance and emissions will suffer. As a service technician, you must be able to quickly and accurately correct ignition system troubles.

The previous chapter covered the fundamentals of ignition system operation. This chapter will let you use this information to diagnose, test, and repair modern ignition systems. Study carefully!

Note!
Chapters 45–47 summarize driveability problems, oscilloscopes, and tune-up procedures. Refer to these chapters for more information on ignition system diagnosis and repair as needed.

Ignition System Problem Diagnosis

Diagnosis of ignition system problems can be very challenging. Because of computer networking, the ignition system and several other systems (fuel, emission, electrical, etc.) all work together. A problem in one system may affect, or appear to affect, the operation of another system.

For example, an inoperative gasoline injector can cause an engine miss or a rough idle. An oil-fouled spark plug can also cause an engine miss. The symptoms for each of these problems will be almost identical. Only proper testing methods will find the faulty component.

Preliminary Checks of Ignition System

Visually inspect the ignition system with and without the engine running. Look for obvious problems: loose primary connections, disconnected spark plug wires, deteriorated secondary wire insulation, cracked distributor cap, and other troubles. At the same time, look over other engine systems. Try to find anything that could upset engine operation. See **Figures 36-1** and **36-2.**

Scanning for Ignition System Problems

With late-model vehicles, especially those equipped with OBD II diagnostic systems, you can connect a scan tool to the vehicle computer to find many ignition-related problems. See **Figure 36-3.** The scan tool can find troubles in the following ignition system circuits and components:

- Crankshaft position sensor.
- Camshaft position sensor.
- Knock sensor.
- Ignition coil(s) primary circuit.
- Ignition coil(s) secondary circuit.
- Timing reference signal.
- Other devices.

If your scan tool readout shows problems with any of these components or circuits, start your pinpoint tests at

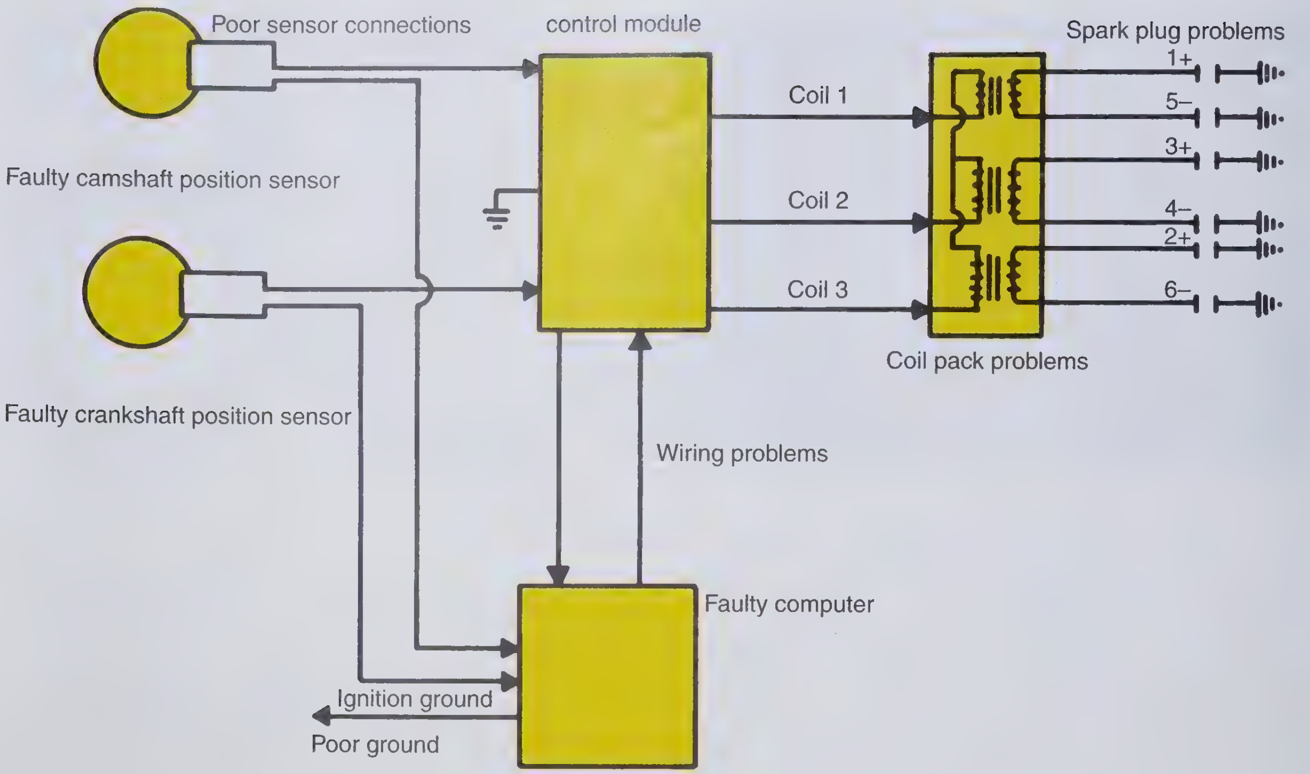

Figure 36-1. Note some of the problems you will find in a distributorless ignition system. (Snap-On Tools)

that part or circuit. You might test the component first and then its circuit. This will depend on the specific circumstances of the symptoms and vehicle design.

If your scanner readout indicates a ***misfire*** condition, the engine may be failing to ignite and burn its air-fuel mixture properly. This increases exhaust emissions, lowers engine power, and increases fuel consumption. Misfire can be caused by problems in the ignition system, the fuel injection system, the emission control system, or the engine itself. Additional tests and the use of more specific scan tool data would be needed to pinpoint the problem causing the misfire condition.

Note!
For more information on on-board diagnostics and misfire conditions, refer to Chapter 18, *On-Board Diagnostics and Scan tools.*

If you are working on a vehicle without on-board diagnostics or a vehicle equipped with an early self-diagnostic system, you will have to use basic testing methods to check logical problem sources.

Performing a Spark Intensity Test

A ***spark intensity test***, or ***spark test***, measures the brightness and length of the electric arc (spark) produced by the ignition system. It is a quick and easy way to check the general condition of the ignition system.

The spark intensity test is often used when an engine cranks but will not start. The test will tell you whether the trouble is in the fuel system (“no fuel” problem) or the ignition system (“no spark” problem). It may also be used to check the condition of the spark plug wires, distributor cap, and other secondary components.

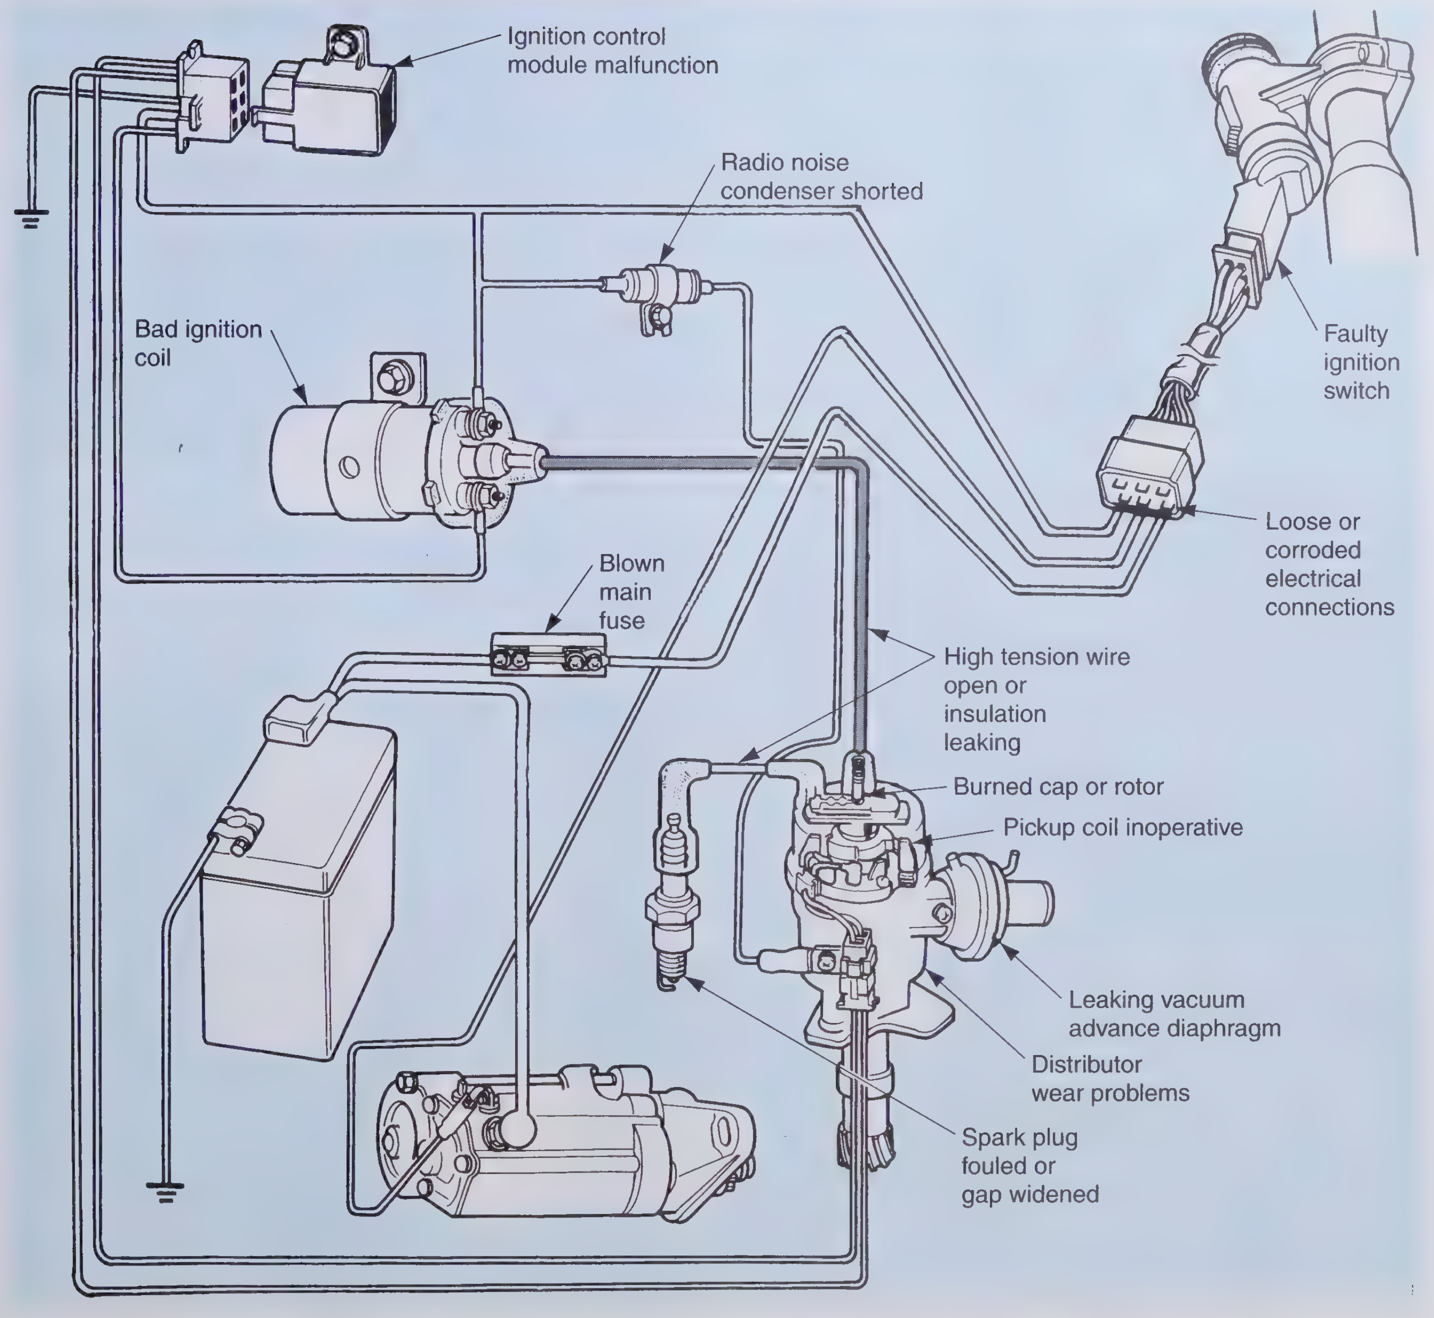
Spark Test Procedures

A ***spark tester*** is a device that is used to check ignition system output voltage. It looks like a spark plug with a very large air gap and a ground wire or clip. Look at **Figure 36-4.**

To perform a spark intensity test:

1. Remove one of the secondary wires from a spark plug.
2. Insert the spark tester into the wire.
3. Ground the tester on the engine.
4. Crank or start the engine and observe the spark at the tester’s air gap, **Figure 36-5.**

Caution!
Only run the engine for a short period of time with a spark plug wire off. Unburned fuel from the dead cylinder could foul and ruin the catalytic converter.



Ignition control module malfunction
Radio noise condenser shorted
Bad ignition coil
Faulty ignition switch
Loose or corroded electrical connections
Blown main fuse
High tension wire open or insulation leaking
Burned cap or rotor
Pickup coil inoperative
Leaking vacuum advance diaphragm
Distributor wear problems
Spark plug fouled or gap widened

Figure 36-2. These problems are common to an electronic ignition system with a distributor. (Honda)

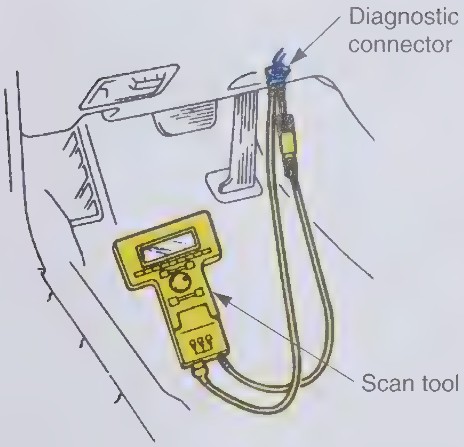
Spark Test Results

A strong spark (wide, bright, snapping electric arc) shows that ignition system voltage is good and that the ignition coil, pickup coil, electronic control unit, and other ignition system parts are functioning. If a strong spark is present, the engine no-start problem may be due to fouled spark plugs, fuel system problems, or engine trouble.

A weak spark or no spark indicates that something is wrong in the ignition system. If the spark is weak at all the spark plug wires, the problem is common to all the cylinders (bad ignition coil, rotor, coil wire). Other tests (to be covered shortly) are needed to pinpoint the trouble.

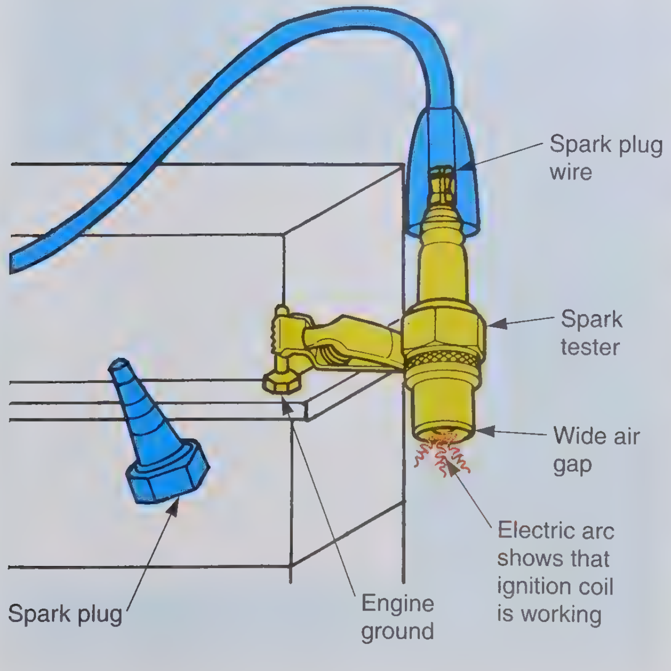
Depending upon the results of your scan tests and spark tests, you may want to check the coil supply voltage if you are not getting a spark. If a coil is not getting voltage or if the coil is faulty, the ignition system will not produce a secondary arc or the arc will be too weak to start combustion. See **Figure 36-6.**

In late-model systems, a bad crankshaft position sensor can upset ignition system operation and keep the engine from starting. Other reasons and tests for a no-spark condition will be discussed shortly.



Diagnostic connector
Scan tool

Figure 36-3. One of the first things normally done when troubleshooting today's vehicles is to connect a scan tool to the diagnostic connector. The scan tool will then give instructions and explanations for finding electrical-electronic problems. OBD II scanners can find problems with the ignition system sensors, the ignition coils, and other components. (Mazda)



Spark plug wire
Spark tester
Wide air gap
Electric arc shows that ignition coil is working
Spark plug
Engine ground

Figure 36-4. Connect the spark tester to the spark plug wire. Ground the tester on the engine. Crank the engine while watching the arc in the tester. No spark or a weak spark indicates ignition system troubles.

Checking for a Dead Cylinder

A ***dead cylinder*** is a cylinder (combustion chamber) that is not burning fuel on the power stroke. There may be ignition system troubles or problems in the engine, fuel system, or another system. A very rough idle and a

Figure 36-5. A bright arc should jump the gap in the spark tester. This tests the general voltage output of the ignition system. (Snap-On Tools)

TECHMASTER
A.W. SPE

Figure 36-6. If you have a no-spark problem, you might want to check for voltage being fed to the ignition coils. Refer to the service manual to find the wire color codes and test points in the circuit. (A. W. Sperry)

puffing noise in the engine exhaust may indicate a dead cylinder. This is an extreme misfire condition because none of the fuel is "firing" and burning.

To check for a dead cylinder, pull off one spark plug wire at a time. On a "live," or firing, cylinder, pulling the wire off will cause engine rpm to drop and idle to become rougher. On a dead cylinder, idle smoothness and rpm *will not change* when the plug wire is removed. After locating a dead cylinder, check for spark and study the spark plug's condition. Also check for low cylinder compression. Some modern engine analyzers automatically check for dead cylinders.

Evaluating the Symptoms

After performing preliminary ignition system tests, you must evaluate the test results and narrow down the possible causes. Use your knowledge of system operation, a service manual troubleshooting chart, basic testing methods, and common sense to locate the trouble. In some cases, the following equipment can be used to help pinpoint the ignition system problem.

Using a Hand-Held Scope (Oscilloscope)

A ***hand-held scope*** is usually a VOM and an oscilloscope combined in one housing. It is a handy tool for advanced troubleshooting of electrical-electronic problems. Like a VOM, the hand-held scope can be used to take voltage, current, and resistance measurements. It can also show the instantaneous voltage variations of a scope. See **Figure 36-7.**

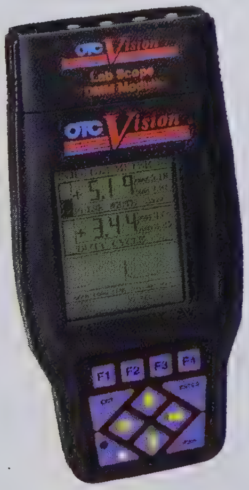

Figure 36-7. A hand-held scope is handy for advanced ignition system testing. It will give voltage, current, and resistance readings. It will also show scope waveforms for advanced troubleshooting of the ignition system and other systems. (OTC)

A scope is sometimes used to check ignition system operating voltages over time. It will also check the output signals from sensors and the signals leaving electronic control units. Voltage is shown horizontally on the oscilloscope screen, while time is shown vertically.

Using an Engine Analyzer

An ***engine analyzer*** contains several types of test equipment (oscilloscope, dwell meter, tachometer, VOM). This equipment is housed in one large, roll-around cabinet. The analyzer is often used to check the operation of an ignition system when problems are hard to find. One type of analyzer is shown in **Figure 36-8.**

Introduced in earlier chapters, an ***oscilloscope,*** or "scope," will precisely measure the operating voltages of an ignition system. It uses a television-type display screen to show voltage changes in relation to time (or degrees of distributor or crankshaft rotation). To determine the condition of the ignition system, the technician can compare the scope test patterns with known good patterns.

Note!
For more information on using a scope or an engine analyzer to test ignition, computer, and other system components, refer to Chapter 46, *Advanced Diagnostics.*

Using an Electronic Ignition Tester

An ***electronic ignition tester*** is an instrument that speeds ignition system diagnosis by indicating specific problems. The ignition tester is connected to the ignition circuit or to a special test plug on the side of the engine compartment. Indicator lights on the tester show whether

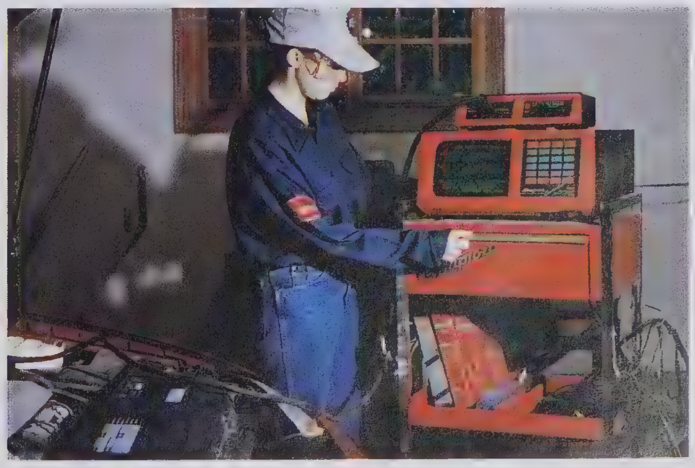

Figure 36-8. An engine analyzer is commonly used to diagnose and locate ignition system problems. The oscilloscope shows ignition system voltages. (Snap-On Tools)

problems exist. Ignition testers are usually make and model specific and are found in large dealerships that service one make of vehicle. They are being replaced by diagnostic scan tools.

Spark Plug Service

Bad spark plugs can cause a wide range of problems, including misfiring, lack of power, poor fuel economy, exhaust odor, and hard starting. After prolonged use, the spark plug tip can become coated with ash, oil, and other substances. This may allow ignition voltage and current to short to ground without arcing or sparking.

The plug electrodes can burn, widening the gap. This can make it more difficult for the ignition system to produce an arc between the electrodes. Wide spark plug gaps require an increased secondary voltage, which can burn other ignition system parts (distributor cap, rotor, ignition module, etc.).

To test the spark plugs, use an oscilloscope or your OBD II scanner misfire readings. Bad plugs will show up as abnormal scope waveforms (trace or pattern) or as a misfire code. Refer to **Figure 36-9.** If a scope is not available or the vehicle does not have OBD II diagnostics, remove the plugs and inspect their condition.

Spark Plug Removal

Before removing the spark plugs, check that the spark plug wires are numbered or located correctly in their clips. Then, grasp the spark plug wire boot and pull the wire off the plug. Twist the boot back and forth if it sticks, **Figure 36-10.**

Spark plug wire pliers are long pliers that have insulation on the handles and jaws. They can sometimes be helpful when removing spark plug wires that are difficult to reach.

Caution!
Never remove a spark plug wire by pulling on the wire. Always grasp and pull on the boot. If you pull on the wire, you can break the conductor in the wire and ruin it.

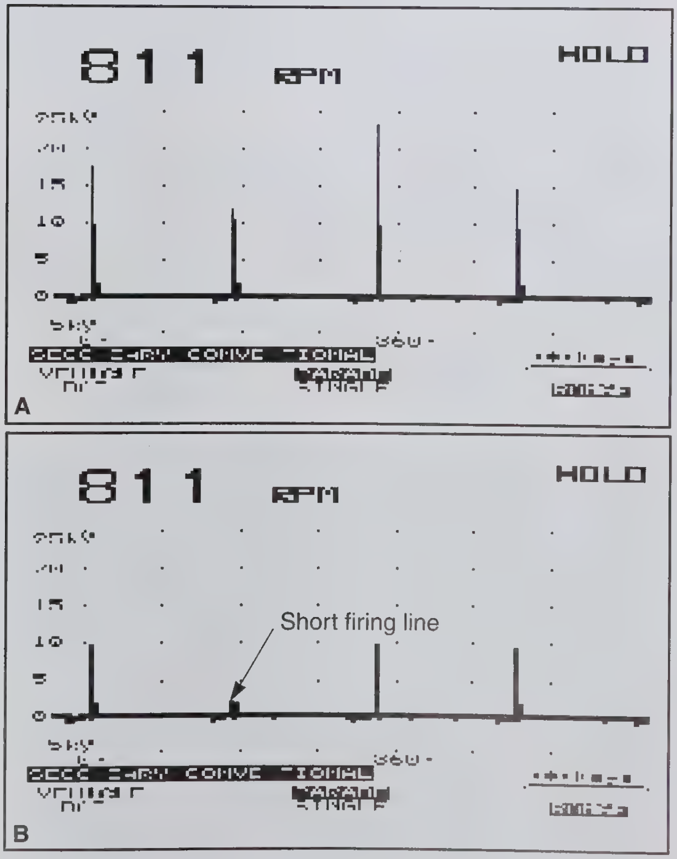

Figure 36-9. Secondary ignition system patterns can provide information on spark plug condition. A—Uneven firing lines are commonly caused by worn spark plugs. B—A short firing line is often caused by a fouled spark plug. (Fluke)

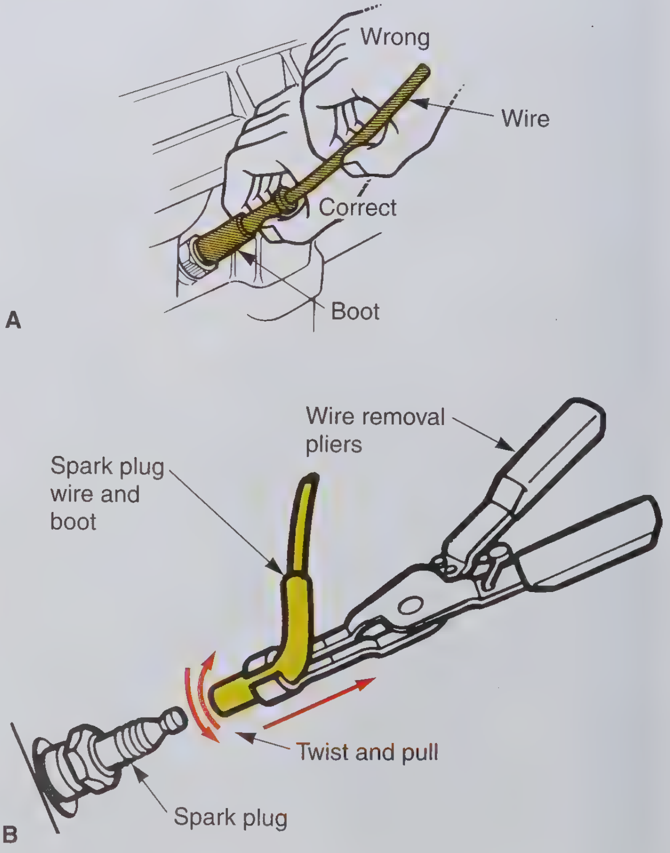

Figure 36-10. When removing a spark plug wire, pull on the boot, never on the wire. A—Using hands to remove a spark plug wire. B—Using special pliers to grasp and pull on the boot. (Toyota and DaimlerChrysler)

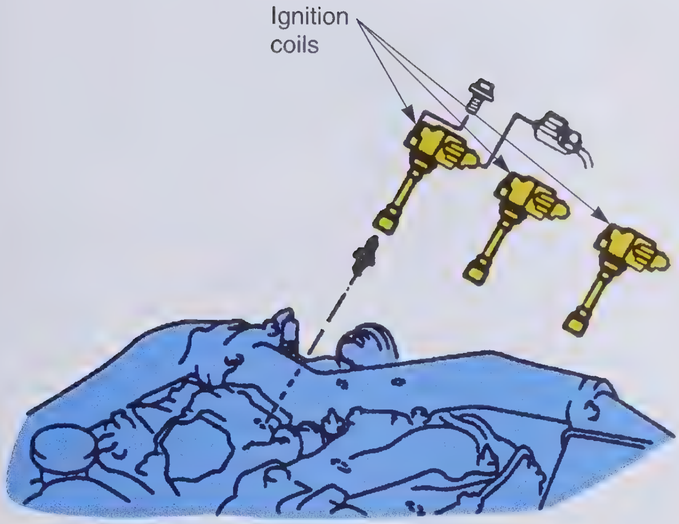

Figure 36-11. In a direct ignition system, the ignition coils are mounted over the top of the spark plugs. You must remove the coils before removing the plugs. Be careful not to drop the small coil mounting screws into the engine. (Mazda)

If the ignition coils are mounted over the spark plugs, the coils must be removed before the plugs can be serviced. Normally, a few small bolts secure the coils. After removing these bolts, you can lift off the ignition coils to gain access to the spark plugs. Look at **Figure 32-11.**

Before removing the plugs, use compressed air to blow debris away from the plug holes. This will prevent particles from falling into the cylinders when the plugs are removed.

Using a spark plug socket, an extension, and a ratchet, as needed, unscrew each spark plug. As you remove the plugs, lay them in order on the fender cover or workbench. Do not mix up the plugs. After all the plugs have been removed, inspect them to diagnose the condition of the engine.

Reading Spark Plugs

To read a spark plug, closely inspect and analyze the condition of its tip and insulator. This will give you information on the condition of the engine, fuel system, and ignition system.

For example, a properly burning plug should have a brown to grayish-tan color.

A black or wet plug indicates that the plug is not firing or that there is an engine problem (worn piston rings and cylinders, leaking valve stem seals, low engine compression, or rich fuel mixture).

Carefully study the spark plug conditions shown in **Figure 36-12**. Learn to read used spark plugs properly. They can provide valuable information when troubleshooting problems.

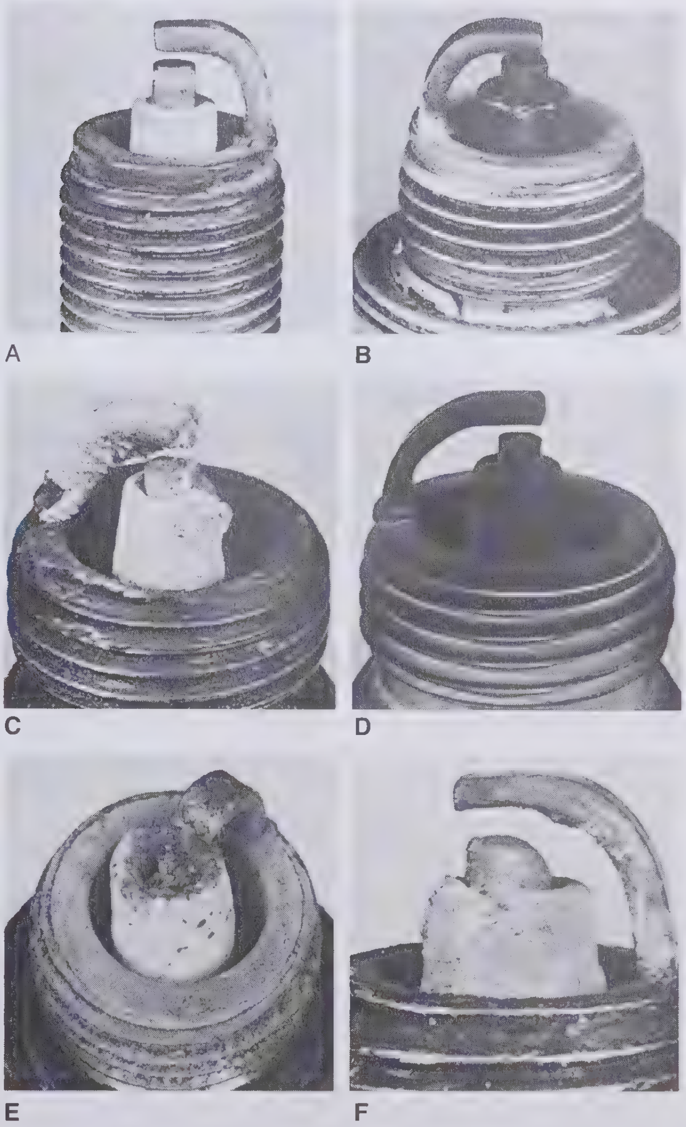

Figure 36-12. Read the spark plugs by inspecting the condition of the insulators and electrodes. Study these typical examples. A—Normal used plug (engine and ignition in good condition). B—Oil-fouled plug (worn rings, scored cylinder, or leaking valve seals). C—Ash-fouled plug (poor fuel quality or some oil entering cylinder). D—Carbon-fouled plug (slow-speed driving, plug heat range too cold, weak ignition, or rich mixture). E—Preignition damage (timing too far advanced, low-octane fuel, or plug heat range too high). F—Normal electrode erosion (old plug with prolonged use). (Champion Spark Plugs)

Cleaning Spark Plugs

Most manufacturers do not recommend spark plug cleaning. Blasting can roughen the insulator and lead to fouling, misfiring, and loss of performance. However, if new spark plugs are not available, used plugs can be cleaned with a ***spark plug cleaner*** (air-powered device that blasts the plug tip with abrasive).

Be very careful that the abrasive (sand) does not wedge up inside the insulator. If this occurs, the sand could fall into the cylinder and cause cylinder scoring. Most shops install new plugs rather than taking the time to clean used spark plugs.

Gapping Spark Plugs

Obtain the correct replacement plug (heat range and reach) recommended by the manufacturer. Then, set spark plug gap by spacing the side electrode the correct distance from the center electrode. If the new spark plugs have been dropped, mishandled, or incorrectly set at the factory, the gap may not be within specifications.

A wire feeler gauge should be used to measure spark plug gap. Slide the gauge between the electrodes, **Figure 36-13.**

If needed, bend the side electrode until the feeler gauge fits snugly in the gap. The gauge should drag lightly as it is pulled in and out of the gap. Spark plug gaps vary from approximately 0.030″ (0.76 mm) on older ignition systems to over 0.080″ (2.03 mm) on electronic systems.

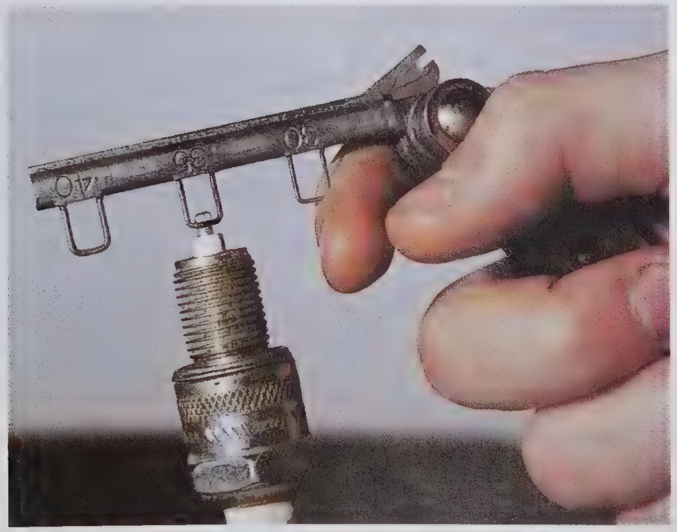

Figure 36-13. To gap a spark plug, use a wire feeler gauge to measure the gap. Both electrodes should just touch the gauge. If needed, bend the side electrode with the gapping tool to achieve the correct electrode spacing. (Snap-On Tools)

Installing Spark Plugs

Spark plugs set to the correct gap are ready for installation. Use your fingers, a spark plug socket, or a short piece of vacuum hose to start the plugs in their holes.

Caution!
Never use the ratchet to start spark plug threads because the plug and cylinder head threads could be crossthreaded and damaged. Hand start the spark plugs to make sure they go in smoothly.

With the spark plugs threaded into the head a few turns by hand, turn them in the rest of the way with your ratchet.

Tighten the spark plugs according to the manufacturer's recommendations. Some manufacturers specify a spark plug torque. Others recommend bottoming the plug on its seat and then turning it an additional one-quarter to one-half turn. Refer to a service manual for exact procedures.

Secondary Wire Service

A faulty spark plug wire can have a burned or broken conductor or deteriorated insulation. An open secondary wire will keep voltage and current from reaching the spark plug. Most spark plug wires have a resistance conductor that is easily damaged.

Secondary wire leakage occurs when the insulation is faulty and sparks jump through the insulation to ground or to another wire. This problem can keep the spark from reaching the spark plugs.

Removing Spark Plug Wires

Before removing spark plug wires, make sure they are numbered. This will simplify installation.

Remove each wire from its plug and from the distributor cap or coil pack. **Figure 36-14** shows several ways spark plug wires are removed from a distributor cap. **Figure 36-15** shows how the spark plug wires are installed in a distributorless ignition system.

Secondary Wire Resistance Test

A ***secondary wire resistance test*** can be used to check the condition of a secondary wire conductor (spark plug wire or coil wire). It is commonly used to check for a bad wire when an oscilloscope is not available or handy.

To perform a wire resistance test, connect an ohmmeter to each end of the secondary wire, **Figure 36-16.** The meter will measure the wire's internal resistance in ohms. Compare your reading to specifications.

Typically, secondary wire resistance should not be over approximately 12,000 ohms per foot or about 50,000 ohms maximum for long wires. Since specifications vary, always check an appropriate service manual for the exact value. A bad spark plug wire will often have almost infinite (maximum) resistance.

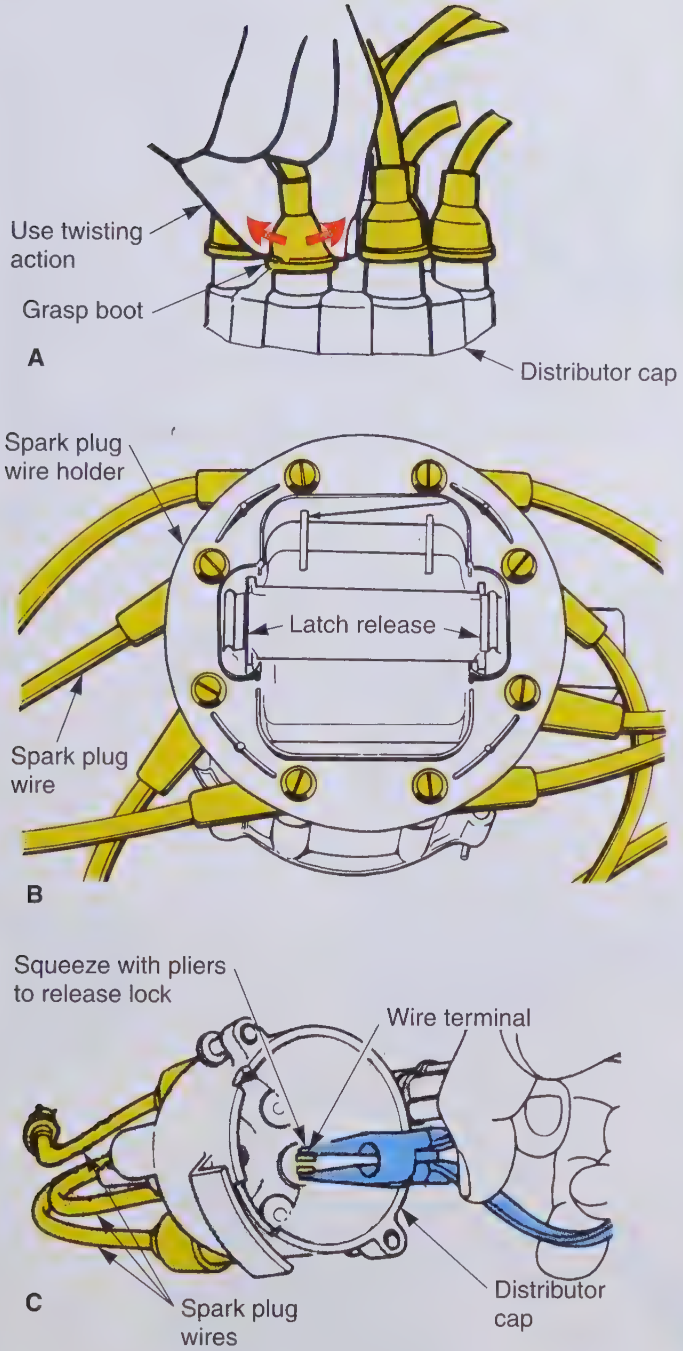

Figure 36-14. Three typical methods of securing spark plug wires in a distributor cap. A—Press fit. Twist and pull on the boot to remove the wire. B—Large ring holds all wires in the cap. Release the latches and lift the ring to release the plug wires. C—Snap locks hold the wire terminals in the cap. Use pliers to free the locks before pulling on the wire boots. (DaimlerChrysler and General Motors)

Secondary Wire Insulation Test

A ***secondary wire insulation test*** is used to check for sparks arcing through the insulation to ground. An ohmmeter test will not detect bad insulation.

To check secondary wire insulation:

1. Darken the shop or place fender covers over the sides of the vehicle's hood to block out light.
2. Start the engine and visually inspect each wire for arcing.
3. If arcing is not evident during the visual inspection, move a high-impedance test light or a grounded screwdriver along the length of each wire. Hold the tip of the tool about 1″ from the wire insulation.
4. If an arc jumps through the insulation and onto the test light probe or the screwdriver, the wire is bad and must be replaced.

Tech Tip!

Secondary wire insulation leakage will usually show up when it rains or in damp weather. The moisture will cause excessive leakage, and the engine may miss or not start.

Replacing Spark Plug Wires

Installing new spark plug wires is simple, especially if one wire is replaced at a time. Compare the length of the old wire with the length of the new wire. Replace each wire with one of equal length. Make sure the new wire is fully attached on the plug and in the distributor or coil module.

Spark plug wire replacement is more complicated if all the wires are removed at once. Then, you must use the engine firing order and cylinder numbers to route each wire correctly.

Figure 36-17 shows a typical service manual firing order illustration. It can be used to trace the spark plug wires from each coil pack tower to the correct spark plug.

Tech Tip!

Some sensor circuits use lower-than-normal reference voltages (1.5V DC). This can make them more susceptible to interference from outside magnetic fields. To prevent induced voltage from entering these sensor wires, always keep spark plug wires in their clips.

Distributor Service

A distributor is critical to the proper operation of an ignition system. It distributes high voltage to each spark plug wire. It may also alter ignition timing and sense engine speed. If any part of the distributor is faulty, engine performance suffers.

Figure 36-15. Service manual illustration gives information for removing and installing spark plug wires in a distributorless ignition system. (Ford)

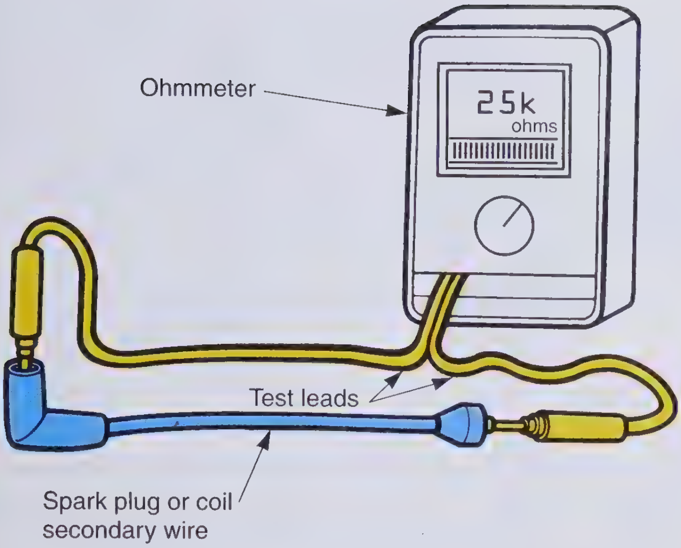

Figure 36-16. To check the conductor in a secondary wire, measure the wire's resistance with an ohmmeter. If the resistance is too high, the conductor or terminal is broken and the wire must be replaced. (DaimlerChrysler)

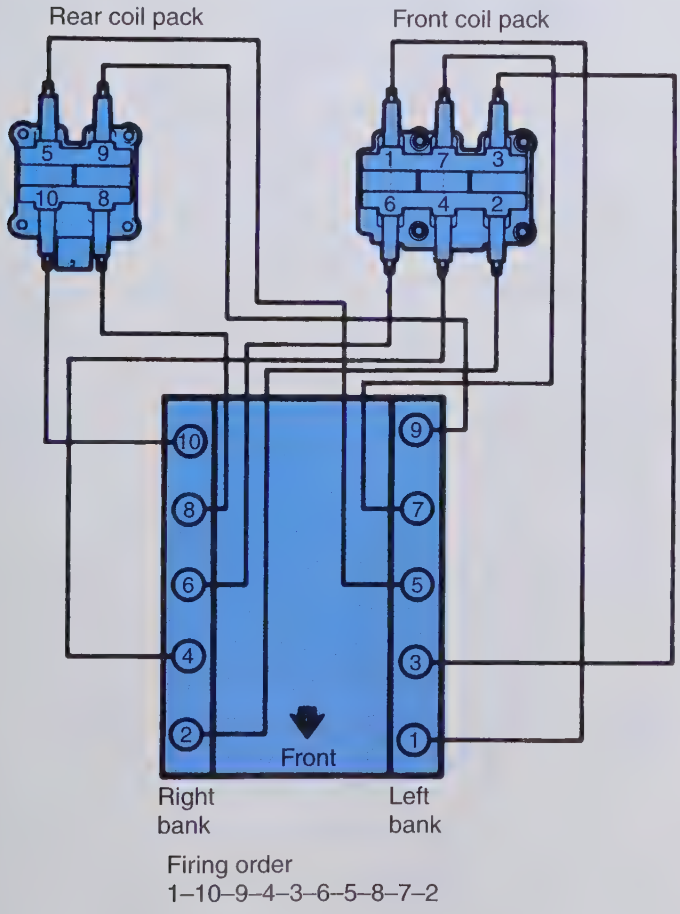

Figure 36-17. If all the spark plug wires have been removed, locate a service manual illustration like this one for your engine. Then, trace and install the wires from the correct distributor cap or coil tower to the proper spark plug. (DaimlerChrysler)

Distributor Cap and Rotor Service

A bad distributor cap or rotor can cause engine missing, ***backfiring*** (popping noise from the throttle body or carburetor), and other engine performance problems.

Trouble often arises when a ***carbon trace*** (small line of carbon-like substance that conducts electricity) forms on the distributor cap, the rotor, the ignition coil, or the coil pack. The carbon trace will short coil voltage to ground or to the wrong plug wire. A carbon trace can cause the spark plugs to fire poorly, out of sequence, or not at all. See **Figure 36-18.**

When problems point to possible distributor cap or rotor troubles, remove and inspect the cap and rotor. Using a drop- light, check the inside of the cap for cracks and carbon traces. A carbon trace is black, making it difficult to see on a black distributor cap or rotor.

If a crack or carbon trace is found, replace the cap and rotor as detailed in the following section. Also check the rotor tip for excessive burning, damage, or looseness. Make sure the rotor fits snugly on the distributor shaft.

Replacing the Distributor Cap and Rotor

Distributor caps can be secured by either screws or spring-type metal clips. Normally, turn the screws counterclockwise for removal. With spring clips, pry on the top of spring clips, being careful not to crack the cap. The clips should pop free. Wiggle and pull upward on the cap to remove it from the distributor body.

Tech Tip!

In unitized distributor arrangements, the center terminal in the distributor cap commonly burns. If the spark plugs have not been changed and their gaps are too wide, high coil voltage will burn the center terminal and cap. Keep this in mind during unitized distributor service.

Rotors may be held by screws, or they may be press-fit onto the distributor shaft. Pulling by hand will usually free a press-fit rotor. Refer to **Figure 36-19.** If stuck, carefully pry under the rotor.

To install a rotor, properly line up the rotor on the distributor shaft. With a press-fit rotor, a tab inside the rotor fits into a groove or slot in the shaft. With a screw-held rotor, the rotor may have round or square dowels that fit into holes in the distributor.

When installing a distributor cap, a notch or tab on the cap must line up with a tab or notch on the distributor housing. This ensures that the cap is correctly aligned

with the rotor. Before securing the spring clips or screws, push down on the cap while twisting it from side to side. Make sure the cap does not wobble on the distributor.

In some ignition systems, the ignition coil is housed inside the distributor cap. In this case, the coil must be taken out of the old cap and installed in the new one.

Caution!
If a distributor cap is not installed correctly, rotor and distributor damage can result. The spinning rotor can strike the sides of the distributor cap, breaking the plastic rotor and cap.

Electronic Ignition Distributor Service

As you have learned, most electronic ignition distributors use a pickup coil to sense trigger wheel (distributor shaft) rotation. The pickup coil sends small electrical impulses to the ignition control module.

If the distributor fails to operate properly, the complete ignition system can stop functioning. It is important to know how to make several basic tests on electronic ignition distributors.

Pickup Coil Service

A bad pickup coil can produce a wide range of engine problems: stalling, missing, no-start troubles, and loss of power at specific speeds. If the tiny windings in the pickup coil break, they can cause problems that only occur under certain conditions. Also, because of vibration and movement, the thin wire leads going to the pickup coil can break. Though the insulation may look fine, the conductor could be damaged inside the insulation. When this happens, the engine may lope, miss, or not run.

Testing a Magnetic Pickup Coil

A magnetic pickup coil or a speed sensor can be located in the distributor or on the engine block (crankshaft speed or position sensor). Tests for either type are similar.

Your scan tool may show a readout of primary circuit problems with a bad pickup coil or crankshaft sensor. Refer to the service manual for details.

A ***magnetic pickup coil test*** compares actual sensor coil resistance or voltage output with specifications. If resistance or voltage output is too high or low, the unit is bad.

To perform a pickup coil test:

1. Connect an ohmmeter or low-reading ac voltmeter across the pickup coil output leads, **Figure 36-20.**
2. Observe the meter reading. Ohmmeter readings will usually vary between 250 and 1500 ohms. If an ac voltmeter is used, a small ac voltage (3–8 V) should be produced by the magnetic pickup coil when the engine is cranked. Check a service manual for exact specifications.
3. Wiggle the wires to the pickup coil while watching the meter. This will help locate a break in the leads to the pickup. Also, lightly tap on the coil with the handle of a screwdriver. This could uncover any break in the coil windings.
4. If the meter reading is not within specifications, or if the reading changes when the leads are moved or the coil is tapped,. replace the pickup coil.

Refer to specifications for exact voltage values and procedures.

Testing Hall-Effect and Optical Sensors

Hall-effect and optical sensors are tested in much the same way as the more common magnetic sensor. You can check their output signals and compare them to specifications. However, they are often tested with a scope to more accurately analyze their output signals.

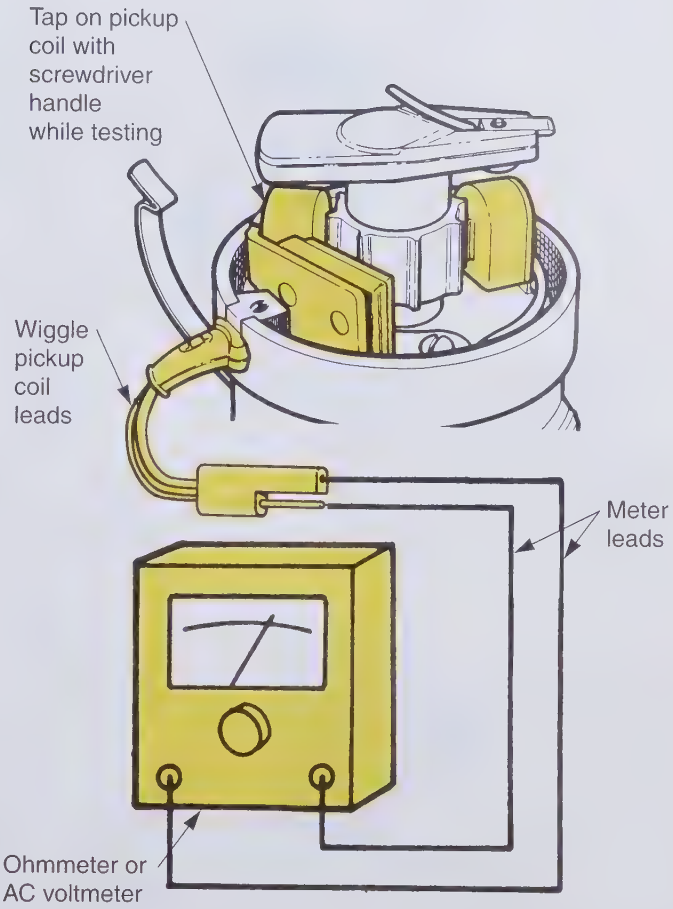

Figure 36-20. Connect an ohmmeter to the pickup coil leads. Wiggle the wires and tap on the coil with a screwdriver handle. If the ohmmeter reading does not remain steady and within specifications, replace the pickup coil. (DaimlerChrysler)

Note!
For information on scope testing magnetic sensors, Hall-effect sensors, optical sensors, etc., refer to Chapter 46, *Advanced Diagnostics.* Earlier chapters on computer system troubleshooting and service also include useful information on testing these sensors.

Replacing the Pickup Coil

A distributor pickup coil can usually be replaced simply by removing the distributor cap, the rotor, and the screws holding the coil to the advance plate. Sometimes the pickup coil is mounted around the distributor shaft. Since procedures vary, find detailed directions for the particular distributor in a service manual. See **Figure 36-21A.**

The ***pickup coil air gap*** is the space between the pickup coil and a trigger wheel tooth. In some designs, it must be set after installing the pickup coil.

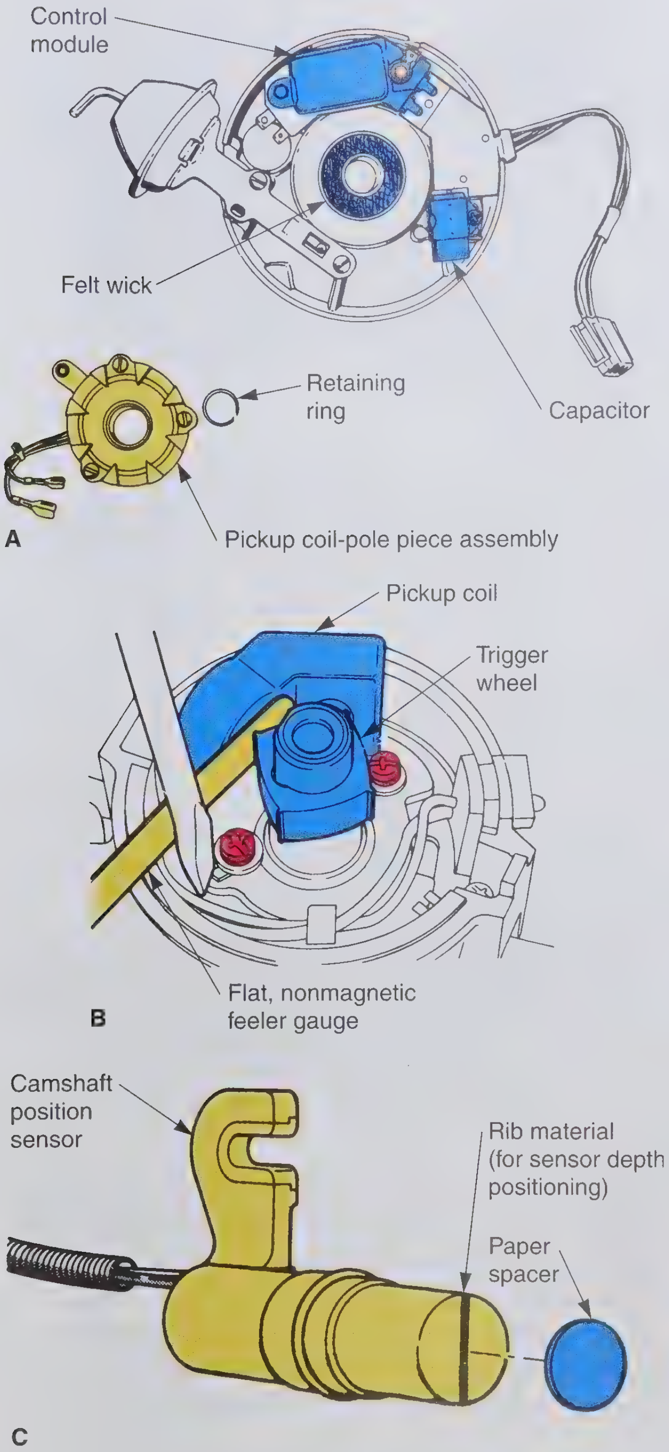

Figure 36-21. A—To remove this pickup coil, you must remove the distributor shaft and the retaining ring. Many other pickup coils can be removed by loosening two screws. B—In some distributors, pickup coil air gap must be measured and adjusted. With a trigger wheel tooth pointing at the pickup, slide the correct nonmagnetic feeler gauge into the gap. Adjust the pickup until the gauge just fits in the gap. C—This crankshaft position sensor must be adjusted. A special paper spacer is stuck on the end of the sensor before the sensor is installed in the block. The spacer will set the correct air gap. The paper spacer must be removed after the sensor mounting screws have been tightened. (Buick and DaimlerChrysler)

To set the air gap, position the trigger wheel so that one of its teeth points at the pickup coil. Slide the correct size nonmagnetic feeler gauge (plastic or brass gauge) between the pickup coil and the trigger wheel tooth. Move the pickup coil in or out until the gauge fits snugly in the gap. Tighten the pickup screws and double-check the air gap setting. Look at **Figure 36-21B.**

Replacing a Crankshaft Position Sensor

The crankshaft position sensor, which is used to monitor engine speed in many modern ignition systems, can be mounted on the front, side, or rear of the engine.

When mounted on the front of the engine, the crankshaft position sensor normally fits into a bracket hole and is secured with a small bolt. When mounted on the side of the engine block, the sensor normally extends into the crankcase and a rubber O-ring seal prevents oil leakage. When installing this type of sensor, always install a new O-ring seal. Make sure there is no debris under the new sensor. This could hold the sensor too far away from its trigger wheel and upset normal operation.

Most crankshaft position sensors simply lock into place and are not adjustable. However, a few require adjustment. Crankshaft position sensor air gap is the distance from the tip of the sensor to an unnotched area on the trigger wheel. This gap must be correct for proper sensor signal output. One method of crankshaft sensor adjustment is shown in **Figure 36-21C.**

Contact Point Distributor Service

Bad contact points (points having burned, pitted, or misaligned contacts or a worn rubbing block) cause a wide range of engine performance problems. These problems include high-speed missing, no-start problems, and many other ignition-related troubles.

A faulty condenser may leak (allow some DC current to flow to ground), be shorted (direct electrical connection to ground), or be open (broken lead wire to condenser foils). A leaking or open condenser will cause point arcing and burning. If the condenser is shorted, primary current will flow to ground and the engine will not start.

Testing Distributor Points

Many technicians visually inspect the surfaces of the contact points to determine their condition. Points with burned and pitted contacts or a worn rubbing block must be replaced. If the points look good, point resistance should be measured. Many dwell-tachometers, have a scale for measuring point resistance.

To measure contact point resistance, crank the engine until the points are closed. Connect the meter to the primary point lead and to ground. If the resistance is too high (out of scale markings for condenser test), the points are burned and must be replaced.

Testing a Distributor Condenser

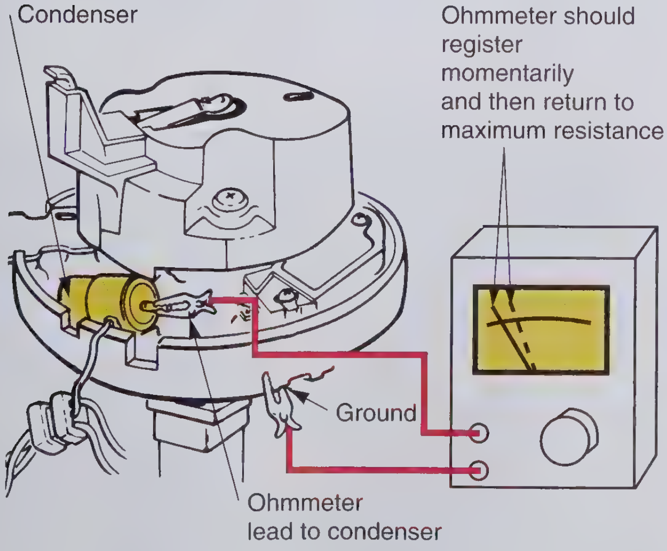
Most technicians simply replace a condenser anytime symptoms point to a condenser problem. However, an ohmmeter can be used to test a condenser.

The ohmmeter is connected to the condenser (capacitor) as shown in **Figure 36-22.** The meter should register momentarily and then return to infinity (maximum resistance). Any continuous reading other than infinity means that the condenser is leaking and must be replaced.

Tech Tip!
An ohmmeter condenser test can also be used to check the noise suppression condensers found in various circuits to prevent radio noise.

Replacing the Points and Condenser

Normally, the distributor points and condenser are held in place by small screws. To prevent dropping the screws, use a magnetic or clip-type screwdriver that firmly holds the screws. If you drop one of the screws under the distributor advance plate (breaker plate), the distributor may have to be removed from the engine to retrieve the screw. Use a small wrench to disconnect the primary wires from the points.



Condenser
Ohmmeter should register momentarily and then return to maximum resistance
Ground
Ohmmeter lead to condenser

Figure 36-22. An ohmmeter can be used to check a condenser for shorts. When the meter is connected, it should register momentarily. Then, as the capacitor charges from the meter current, the reading should return to infinity. A continuous reading indicates a shorted condenser. (Echlin)

Wipe the distributor cam and advance plate clean before installing the new parts. If recommended, apply a small amount of oil to lubrication points on the distributor (wick in the center of shaft, cam wick, or oil hole in the side of the distributor housing). Do not apply too much oil because it could get on the points.

To prolong service life, place a small amount of grease on the side of the breaker arm rubbing block. This will reduce friction between the distributor cam and the fiber block.

Fit the points into the distributor. Install the point screws, the condenser, and the primary wires. If the distributor cap has a window (square metal plate), fully tighten the point hold-down screws. If the distributor cap does not have a window, only partially tighten the screws so the points can be adjusted.

Adjusting Distributor Points

Distributor points can be adjusted using either a feeler gauge (metal blade ground to precise thickness) or a dwell meter.

To use a feeler gauge to gap (set) distributor points, crank the engine until the points are fully open. The point rubbing block should be on top of a distributor cam lobe. This is illustrated in **Figure 36-23.**

Distributor point gap is the recommended distance between the contacts in the fully open position. Look up this specification in the service manual. It may also be given on the emission sticker in the engine compartment. Typical point gap settings average around 0.015″ (0.38 mm) for eight-cylinder engines and 0.025″ (0.53 mm) for six- and four-cylinder engines.

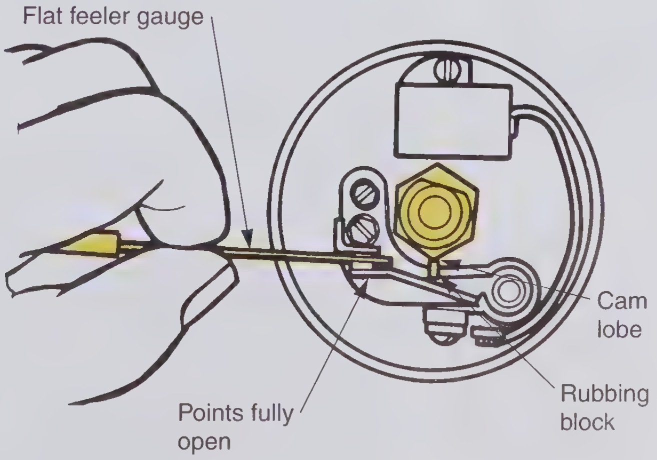


Figure 36-23. To set the points, “bump” the engine until the cam lobe is pushing on the rubbing block. The points must be fully open. Slide the correct thickness feeler gauge between the points. Open or close the points until the gauge just touches both contacts. (DaimlerChrysler)

With the distributor points open, slide the specified thickness feeler gauge between the points, **Figure 36-23.** Adjust the points so that there is a slight drag on the blade of the gauge. Use a screwdriver or an Allen wrench, depending on point design, to open or close the points. If needed, tighten the hold-down screws and recheck point gap.

Make sure your feeler gauge is clean before inserting it between the points. Oil or grease will reduce the service life of the points.

Using a Tach-Dwell Meter

The ***tach-dwell meter*** is composed of a tachometer and a dwell meter. It can be used to measure engine speed, dwell, and sometimes, resistance.

The ***tachometer,*** or ***tach,*** section of the tach-dwell meter measures engine speed by checking how often the ignition coil(s) fires. The tach is often used to adjust engine idle speed or to check engine speed during ignition timing adjustment.

The ***dwell meter*** portion of the tach-dwell meter measures current flow as compared to degrees of engine crankshaft or distributor rotation. On contact point ignition systems, it is used to measure point dwell, which is the time the points are closed and conducting primary current through the ignition coil windings. On electronic ignition systems, the dwell meter is used to measure the amount of time the ignition control module conducts current through the ignition coil(s).

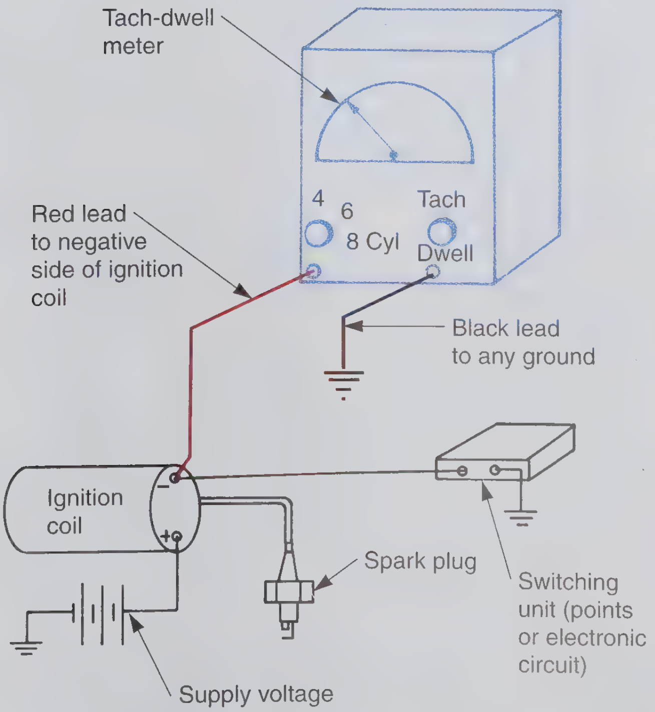

Figure 36-24. A tach-dwell meter is connected to contact point and some electronic ignition systems as shown. (TIF)

When using a dwell meter to adjust distributor points, follow the directions provided with the meter, **Figure 36-24.** Typically, connect the red lead to the distributor side of the coil (wire going to contact points). Connect the black lead to ground (any metal part on engine).

If an opening is provided in the distributor cap, the points should be set with the engine running. Install the distributor cap and rotor. Start the engine. With the meter controls set properly, adjust the points using an Allen wrench or a special screwdriver-type tool. Turn the point adjustment screw until the dwell meter reads within specs.

If the distributor cap does not have an adjustment window, set the points with the cap removed. Instead of starting the engine, ground the coil wire (connect output end on engine). Crank the engine with the starting motor. This will simulate engine operation and allow point adjustment with the dwell meter.

Dwell

Dwell specifications vary with the number of cylinders in the engine and the type of ignition system (point, electronic, or computerized). An 8-cylinder engine with contact points will usually require 30° of dwell. An engine with fewer cylinders will normally require more dwell time.

An electronic or computer-controlled system can have different amounts of dwell time to energize the ignition coil(s). Always obtain exact dwell values from a tune-up chart or shop manual.

Fixed and Variable Dwell

With modern electronic or computer-controlled ignition systems, the dwell can vary with system design. There are a few terms you should understand concerning ignition dwell.

Fixed dwell means that the dwell time should remain the same at all engine speeds. Fixed dwell is found on contact point systems and older electronic systems. If the dwell varies when it should not, it is usually due to distributor shaft or bushing wear or an ignition control module failure.

Variable dwell means the engine control module alters ignition coil dwell time with engine speed. This is common in most late-model vehicles. At low engine speeds, the control module can use a shorter dwell period to build an adequate magnetic field around the coil windings for good spark. However, at higher engine speeds, the module increases dwell time to make sure the coil(s) fires the spark plugs properly. If a system fails to alter dwell when it should, the engine control module has a problem and should be replaced.

Current-limiting dwell means the engine control module sends high current through the ignition coil windings until a strong magnetic field is developed around the windings. Once the module senses a ***saturated ignition coil*** (coil's magnetic field is fully formed), it reduces the amount of current sent through the coil windings. Only a small primary current is needed to maintain the strong magnetic field in the coil. At high engine speeds, the current-limiting feature may not be needed. Full control module current output may be needed to fully charge the ignition coil to ready it to fire the spark plugs at high engine rpm.

Ignition Timing Adjustment

Initial ignition timing is the spark timing set by the technician with the engine idling (no advance). It must be adjusted whenever the distributor has been removed and reinstalled in an engine. During a tune-up, initial timing must be checked and then adjusted if not within specifications. Ignition timing is sometimes checked with a timing light, **Figure 36-25.**

Initial ignition timing is sometimes adjusted by turning the distributor housing in the engine. This makes the pickup coil and electronic control unit (or the contact points) fire the ignition coil earlier or later.

Many computer-controlled ignition systems have no provision for timing adjustment. A few, however, have a tiny screw or lever on the computer for minor ignition timing changes.

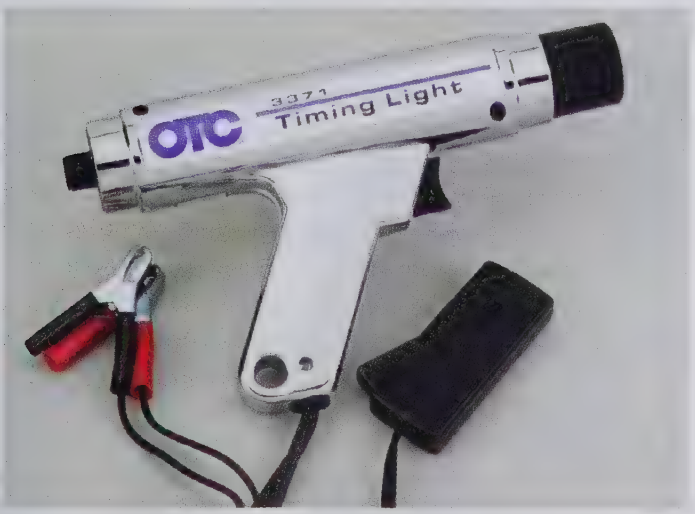

Figure 36-25. A timing light is sometimes used to check ignition timing. (OTC)

When the ignition timing is *too advanced,* the engine may suffer from spark knock or ping. A light tapping sound may result when the engine accelerates or is under a load. The ping (abnormal combustion) will sound like a small hammer tapping on the engine.

When ignition timing is *too retarded,* the engine will have poor fuel economy and will lack power. It will also be very sluggish during acceleration. If timing is extremely retarded, combustion flames blowing out of the opened exhaust valves can overheat the engine and crack the exhaust manifolds.

Energizing Base Timing

Base timing is the ignition timing without computer-controlled advance. Base timing is checked by disconnecting a wire connector in the computer wiring harness or by jumping across specific pins on a service connector, **Figure 36-26.** The connector may be on the engine, next to the distributor, or in the passenger compartment. Refer to a manual for the exact location. When in the base timing mode, you can use a conventional timing light to measure ignition timing.

Measuring Ignition Timing

A ***timing light*** is sometimes used to measure ignition timing. As shown in **Figure 36-27,** a timing light normally has three leads. The two small leads connect to the battery. The larger lead generally connects to the *number one* spark plug wire.

Depending on the type of timing light, the large lead may be connected directly to the metal terminal of the

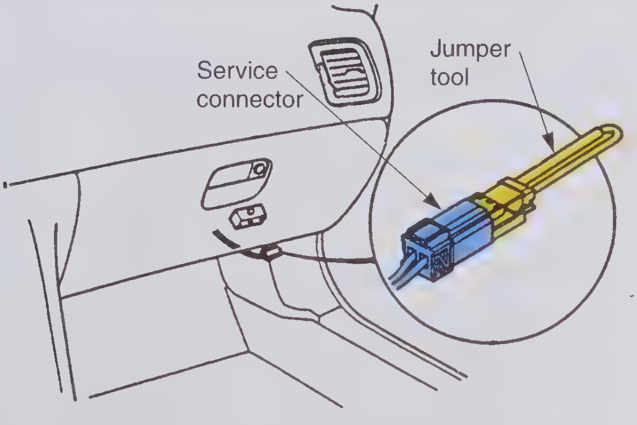

Figure 36-26. With many computer-controlled ignition systems, you must trigger base timing to shut off the electronic advance. You may have to jump across special connector terminals or disconnect a timing connector. (Honda)

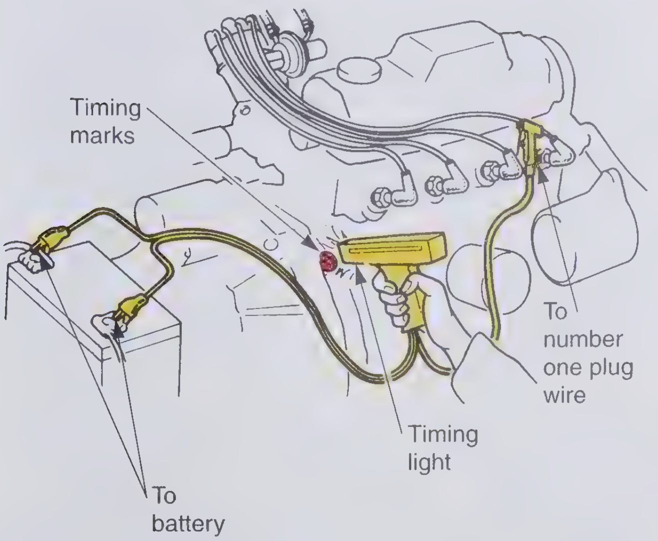

Figure 36-27. A timing light is connected to the system as shown. The large lead connects to the number one spark plug wire. The small leads connect to the battery. The light is aimed at the timing marks on the flywheel or at the front engine cover and damper. (Honda)

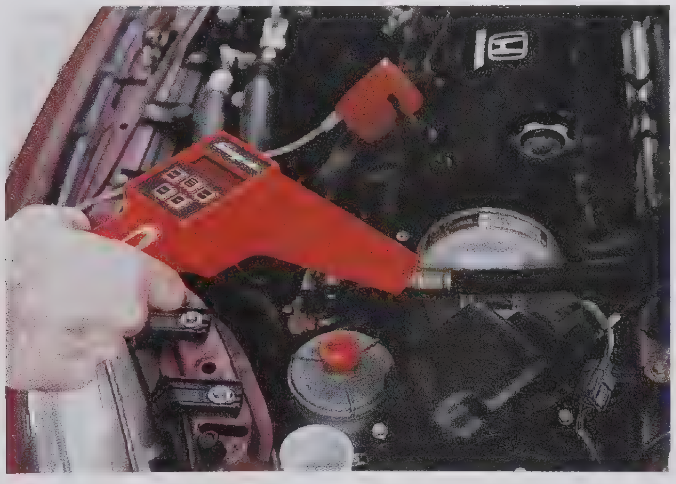

Figure 36-28. Timing marks can be difficult to see on modern vehicles. Find the correct angle for shining the light and viewing the marks when adjusting ignition timing. (Snap-On Tools)

plug wire (conventional type) or it may clip around the spark plug wire (inductive type).

When the engine is running, the timing light will flash *on* and *off* like a strobe light. The flashing action can make a moving object appear stationary (stand still), so it can be viewed.

Before measuring engine timing, disconnect and plug the vacuum advance hose going to the distributor (if used).

Start the engine and aim the timing light at the timing marks, **Figure 36-28.** The timing marks may be on the front cover and harmonic balancer of the engine. The timing marks may also be on the engine flywheel. **Figure 36-29** shows ignition timing marks.

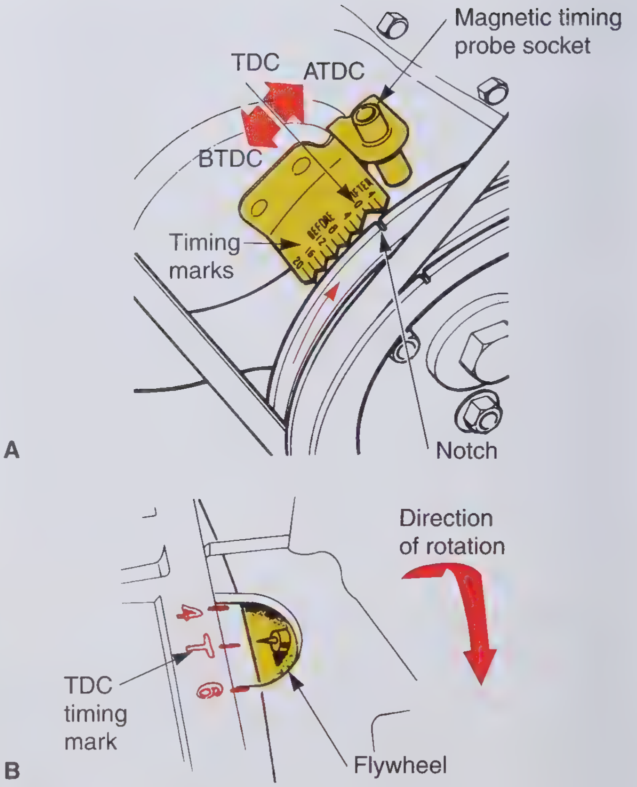

Figure 36-29. A—Timing marks on the front of the engine. B—Timing marks on the engine flywheel and clutch housing. (DaimlerChrysler and Honda)

The flashing timing light will make the mark or marks on the harmonic balancer or flywheel appear to stand still. This will let you determine whether or not the engine is timed properly. For example, if there is only one reference line on the harmonic balancer, simply read initial timing by noting the degree mark that is aligned with the reference line, as in **Figure 36-30.**

Tech Tip!
Sometimes a dual trace scope is needed to check ignition timing. One scope lead is connected to the ignition coil primary and another is connected to the crankshaft position sensor. The two waveforms can be compared to measure ignition timing advance or retard.

Ignition Timing Specifications

Ignition timing is very critical to the performance of an engine. If the timing is off by even 2 or 3 degrees, fuel economy and power can drop considerably. Always obtain the exact timing specifications from the vehicle's emission control sticker or an appropriate service manual.

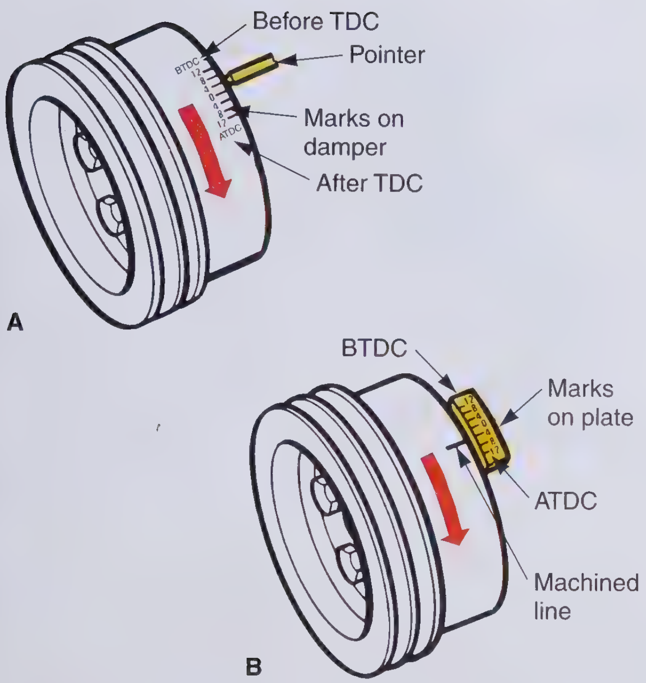

Figure 36-30. A—When degree markings are on a moving damper, read the marking lined up with the pointer. B—With stationary degree markings, read the marking lined up with the line machined in the damper. When the timing light is aimed at the markings, the rotating marks will appear to be stationary. (DaimlerChrysler)

Adjusting Ignition Timing

If the timing marks do not line up correctly, the ignition timing must be adjusted. As previously mentioned, timing can sometimes be adjusted by rotating the distributor or by moving the mounting for the engine speed sensor or crankshaft position sensor. In a few systems, a tiny screw or lever is provided for minor timing adjustments. Refer to an appropriate service manual for exact procedures

Tech Tip!
In some systems, ignition timing cannot be adjusted. If timing is incorrect in these systems, the ECM or another component affecting timing must be replaced. Refer to the service manual for more information on specific vehicles.

To adjust timing in systems that require rotating the distributor:

1. Loosen the distributor hold-down bolt. A ***distributor wrench*** (long, specially shaped wrench for reaching under distributor housing) is handy for this purpose, **Figure 36-31.** Only loosen the distributor bolt enough to allow distributor rotation. Do *not* remove the bolt.

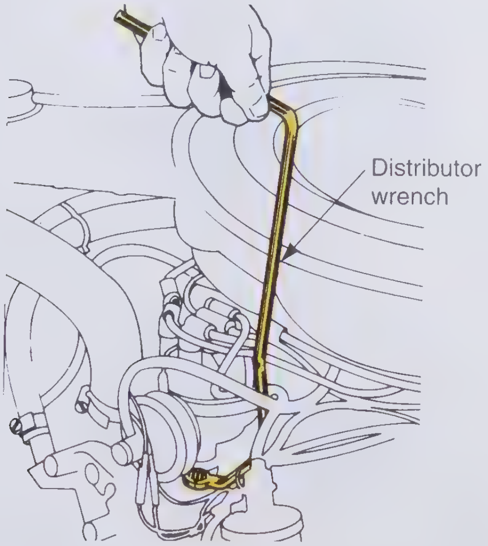

Figure 36-31. A distributor wrench may be needed to loosen the hold-down bolt on the distributor. The bolt can be hard to reach. (K-D Tools)

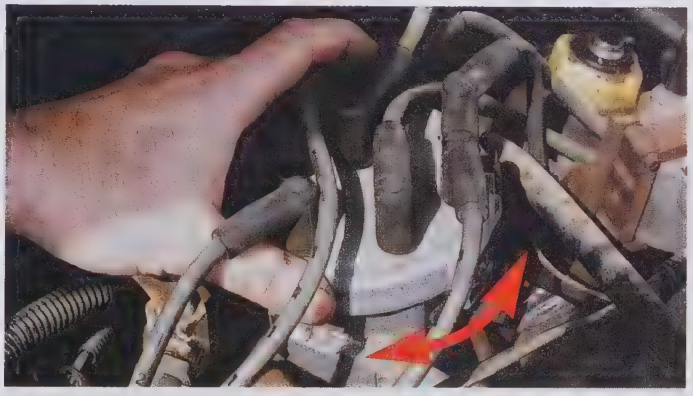

Figure 36-32. To change ignition timing, turn the distributor housing in the engine. Turning the distributor in the direction of rotor rotation will retard timing. Turning the distributor against rotor rotation will advance timing.

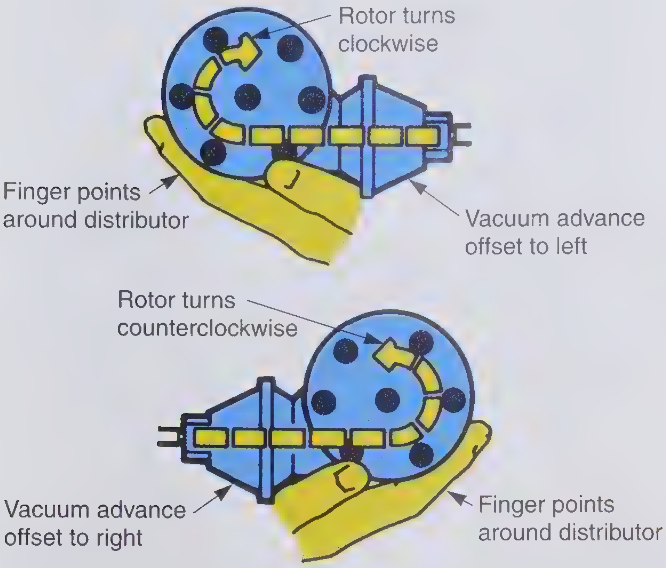
2. Shine the timing light on the engine timing marks.
3. Turn the distributor one way or the other until the timing marks line up correctly, **Figure 36-32.**
4. Tighten the hold-down bolt and double check the timing.
5. Reconnect the distributor vacuum hose and disconnect the timing light.

Warning!
Keep your hands and the timing light leads away from the engine fan and belts. The spinning fan and belts can damage the light or cause serious injury!



Rotor turns clockwise

Rotor turns counterclockwise
Vacuum advance offset to right
Finger points around distributor

Figure 36-33. Use the finger rule to determine the direction of rotor rotation. Point around the distributor as shown. This will tell you how the rotor turns without removing the cap and watching the rotor. The direction of distributor rotation is needed when installing spark plug wires and setting ignition timing. (Florida Dept. of Voc. Ed.)

Turning the distributor housing against distributor shaft rotation advances the timing. Turning the housing with shaft rotation retards the timing, **Figure 36-33.** With modern computer advance distributors, an arrow is sometimes stamped on the cap to show direction of shaft rotation.

Testing Centrifugal and Vacuum Distributor Advance Systems

Both contact point–type distributors and older electronic distributors use similar advance mechanisms. A faulty advance mechanism will reduce engine performance and fuel economy. A timing light can be used to test the general operation of a centrifugal advance mechanism. Connect the timing light. Remove the vacuum hose going to the distributor. Start and idle the engine.

While shining the timing light on the engine timing marks, slowly increase engine speed to approximately 3500 rpm. Note the movement of the timing mark. If the centrifugal advance is working, the mark should steadily move to a more advanced position with the increase in speed. See **Figures 36-34A** and **36-34B.** If the timing mark jumps around or does not move, the centrifugal advance mechanism is faulty. It may be worn or rusted. It may also have weak springs or other mechanical problems.

To test the distributor vacuum advance, connect a timing light. Remove the vacuum advance hose from the distributor. Start the engine and increase its speed to approximately 1500 rpm. Note the location of the timing marks. Then, reconnect the vacuum hose on the distributor diaphragm.

As soon as vacuum is reconnected, engine speed should increase and the timing mark should advance. See **Figure 36-34C.** If the vacuum advance is not working, check the vacuum advance diaphragm and the supply vacuum to the distributor.

Testing Vacuum Advance Diaphragm

To test the vacuum advance diaphragm, apply a vacuum to the unit using a vacuum pump, **Figure 36-35.** When vacuum is applied to the diaphragm, the advance plate in the distributor should swing around. When vacuum is released, the advance plate should snap back to its normal position.

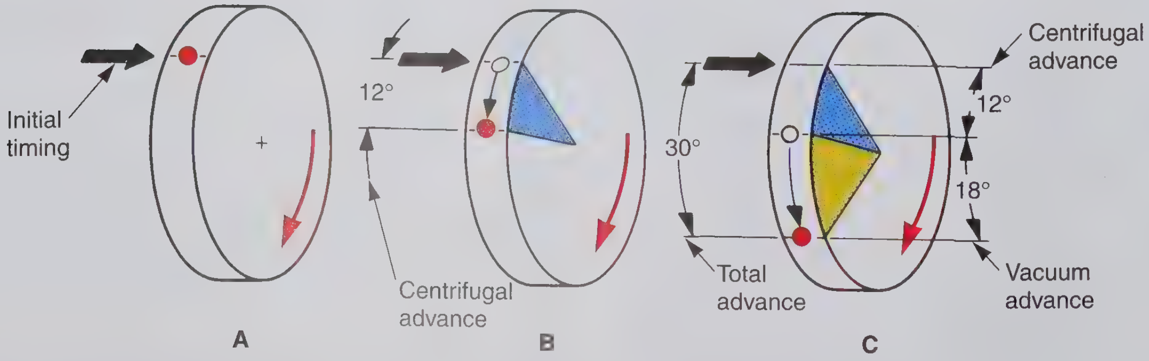

Figure 36-34. Timing advance mechanisms can be tested with a timing light. A—With the engine idling and the vacuum advance hose disconnected, initial timing marks should line up. B—When you increase engine speed, the timing marks should move to an advanced position. C—With vacuum applied to the distributor advance diaphragm, timing should advance more and be within specifications. (Snap-On Tools)

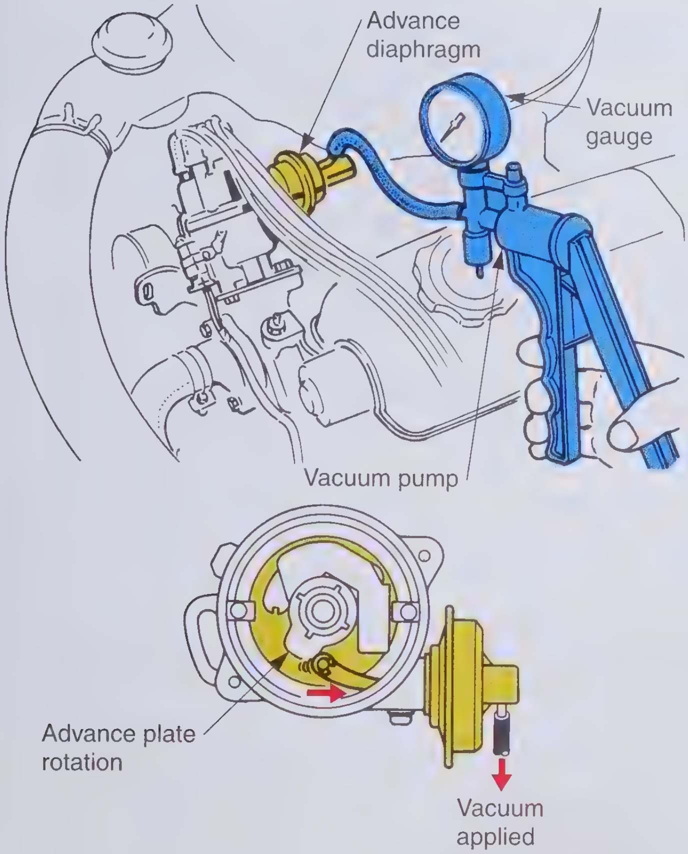

Figure 36-35. A leaking vacuum advance diaphragm is a common problem that will greatly reduce fuel economy. Use a vacuum pump to check for leakage. (Honda)

If the advance diaphragm leaks and will not hold vacuum, it must be replaced. If the advance mechanism is stuck, check components for binding, rust, or other problems.

To check the supply vacuum going to the distributor, disconnect the diaphragm vacuum hose. Connect it to a vacuum gauge. Measure the amount of vacuum with the engine running at a specified rpm. If the vacuum is not sufficient, check all components controlling vacuum to the distributor (carburetor, thermal vacuum switch, delay valve, vacuum hose).

Tech Tip!
The methods for checking a vacuum advance diaphragm can be applied to the vacuum diaphragms found in other systems (transmission, speed control, emission control, etc.).

Measuring Distributor Advance

A special timing light is available that can measure the exact distributor advance with the distributor installed in the engine. This timing light has a degree meter built into the back of its case. The meter will register advance quickly and accurately.

A ***distributor tester*** may also be used to check distributor operation. The distributor is removed and mounted in the tester. The tester will check all primary distributor functions (pickup coil output, point dwell, centrifugal and vacuum advance).

Removing the Ignition Distributor

Before removing a distributor, carefully mark the position of the rotor tip on the distributor housing and the engine with a scribe or marking pen. Look at **Figure 36-36.** Then, if the engine crankshaft is not rotated, you will be able to reinstall the distributor by simply lining up your marks.

To remove the distributor, take off the distributor cap, rotor, primary wires, and distributor hold-down bolt. Pull the distributor upward while rotating it back and forth. If stuck, use a slide hammer puller with a two-prong fork.

Keep in mind that distributor locations and service procedures can vary. For example, the distributor on one high-performance V-8 engine is mounted on the front of the engine, under the water pump, **Figure 36-37.**

Rebuilding a Distributor

A distributor rebuild involves disassembly, cleaning, inspection, worn part replacement, and reassembly. Depending on the distributor type, exact procedures vary, **Figure 36-38.** Always refer to a shop manual for detailed

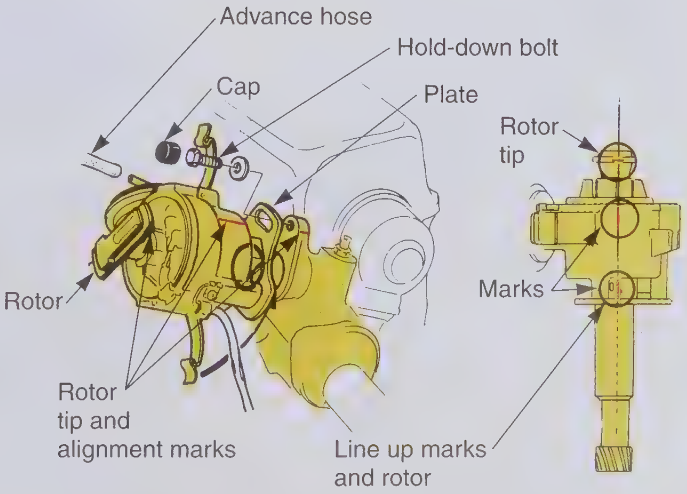

Figure 36-36. Before removing a distributor, mark the distributor housing and the engine below the rotor tip. This will let you quickly reinstall the distributor so the engine will at least start and run. (Honda)

directions and specifications. The trend is to install a new or factory rebuilt unit. Many late-model distributors cannot be rebuilt in the shop.

The major steps for distributor disassembly are illustrated in **Figure 36-39.** Assemble the distributor in reverse order of disassembly. See **Figure 36-40.**

Installing a Distributor

If you made reference marks and the engine crankshaft was not turned, install the distributor as it was removed. Align the rotor with the marks on the distributor housing and the engine. Double-check the position of the rotor after installation because the rotor will turn as the distributor gear meshes with its drive gear.

To install a distributor when the engine crankshaft has been rotated, remove the number one spark plug. Bump (crank) the engine until you can feel air blowing out of the spark plug hole. As soon as air blows out, slowly turn the crankshaft until the engine timing marks are on TDC.

With the crankshaft in this position, fit the distributor into the engine so that the rotor points at the number one distributor cap tower. Also, make sure the distributor housing is installed properly. The advance unit should be pointing as it was before removal.

Ignition Supply Voltage Test

Discussed briefly, an ***ignition supply voltage test*** checks the voltage going to the positive terminal of the ignition coil. It checks the circuit between the battery feed wire and the coil. An ignition supply voltage test will help locate troubles in the:

- Ignition switch.
- Bypass circuit.
- Resistance circuit.
- Electrical connections and primary wires.

If the ignition system fails a spark test, a supply voltage test may help locate the source of the problem.

Connect a high-impedance test light to the battery side of the coil. The light should glow with the engine cranking and with the ignition switch in the *run* position. If it does not glow, there is an open somewhere in the

primary supply circuit. Perform voltage drop tests until the point of high resistance is found.

A ***resistance wire*** performs the same basic function as a ballast resistor—it limits the voltage going to the coil to prevent coil overheating and damage. If the voltage going to the ignition coil is low or high, measure the resistance of the resistance wire. Compare the ohmmeter reading to specifications. Replace the wire if needed.

Tech Tip!
Many late-model ignition systems apply full battery voltage to the ignition coil primary terminal. See **Figure 36-41.**

Ignition Coil (Coil Pack) Service

A faulty ignition coil may result in a weak spark, an intermittent spark, or no spark at all. The engine may miss or stall. In some cases, the engine may not start at all. The windings inside the coil can break, producing a resistance or an open in the coil circuit. In some cases, the engine will stop running when the coil heats up. The heat from the engine can make the coil windings expand and open, with a resulting loss of high-voltage output.

A bad coil pack may only affect two cylinders. The other coils in the assembly may be working normally. If you find misfiring or two dead cylinders that correspond to one coil in a coil pack, suspect the coil pack.

Figure 36-41. If you have a no-spark problem, make sure that voltage is being fed to the ignition coil(s).

Testing the Ignition Coil or Coil Pack

A coil test may be needed when the ignition system fails the spark test but proper supply voltage is found. Since coil designs are different, testing procedures vary.

Generally, an ohmmeter is used to measure the internal resistance of the coil windings. Follow the manufacturer's instructions to check the resistance of both the primary and secondary windings. See **Figure 36-42.** A reading that is out of specifications indicates a faulty ignition coil.

With a coil pack, test the windings of the coil with the spark problem. If, for example, the number two cylinder is not firing, the coil for that cylinder should be checked first. Normally, a bad coil pack winding will show infinite resistance, or open. **Figure 36-43** shows how to test one make of coil pack.

Figure 36-42. With a weak spark, you may need to test the ignition coil. Follow the service manual instructions to measure the resistance of the windings. A—Checking a coil mounted in the distributor cap. B—Checking an externally mounted ignition coil. (Peerless and Echlin)

Replacing an Ignition Coil

When the ignition coil or coil pack is mounted on the engine, coil replacement involves removing the wires and bolts securing the old coil and lifting the coil from the engine. Then, simply bolt on the new coil in place and reconnect all wires, **Figure 36-44.**

Be careful not to connect the coil in ***reverse polarity*** (primary wires accidentally connected backwards). This would reduce secondary voltage output.

Engine

Figure 36-44. If a coil pack is bad, it must be replaced. Keep the spark plug wires organized so they can be quickly reinstalled on the correct coil towers. (Cadillac)

When the coil is mounted inside the distributor cap (unitized type ignition), the distributor cap must be removed to install the new coil.

Ignition Switch Service

A bad ignition switch can cause several problems: the engine may not crank or start, the engine may not shut off when the ignition key is turned off, or the starter may not disengage when the ignition key is returned to *run.* When these types of problems occur, the ignition switch should be tested.

Testing an Ignition Switch

A test light can be used to check the action of an ignition switch. When a test light is touched to the *start* terminal on the back of the switch, the light should glow only when the key has been turned to *start.* It should not glow when the key is released to the *run* position.

In the *run* position, the test light should glow when touched on the *run* terminal of the switch. With the ignition key in the *off* position, neither terminal (start or run) should make the test light glow.

Replacing an Ignition Switch

If the ignition switch is defective, it must be replaced. Before removing a dashboard-mounted switch, the ***tumbler*** (lock mechanism) must be removed from the switch. Normally, a small piece of wire is inserted into a hole in the front of the switch and the key is turned. This will release the tumbler from the switch so the tumbler can be pulled free. Then, unplug the wires and remove the old switch.

A steering column–mounted ignition switch is separate from the tumbler, **Figure 36-45.** It is normally about halfway down and on top of the steering column. To remove this type of switch, remove the fasteners holding the steering column to the dash. This will let the column drop down so you can replace the ignition switch.

Ignition Control Module Service

A faulty ignition control module will produce a wide range of problems: engine stalls when hot, engine cranks but fails to start, engine misses at high or low speeds, etc.

B—A small rod runs down the column to the ignition switch. To remove the switch, drop the column by removing the column-to-dash fasteners. Then, remove the small nuts holding the switch to the top of the column. (Florida Dept. of Voc. Ed. and Ford)

Quite often, an ignition control module problem will show up after a period of engine operation. Engine heat will soak into the module, raising its temperature. The heat will upset the operation of the electronic components in the unit.

Testing an Ignition Control Module

Many shop manuals list the ignition control module as one of the last components to test when troubleshooting an ignition system. If all the other components are in good working order, then the problem might be in the ignition control module.

If a specialized tester is available, it may be used to quickly determine the condition of the ignition control module. The wires going to the module are unplugged and the tester is connected to the module. The tester will then indicate whether an ignition control module fault exists.

Heating an Ignition Control Module

The microscopic components (transistors, diodes, capacitors, resistors) inside the ignition control module are very sensitive to high temperatures and vibration.

When testing the control module, many technicians use a heat gun or lightbulb to warm the unit. This will simulate the temperature in the engine compartment after the engine has been running. The heat may make the control module act up and allow you to find an intermittent problem. Refer to **Figure 36-46.**

Do not apply too much heat to an ignition control module or it may be ruined. Only heat the unit to a temperature equal to its normal operating temperature.

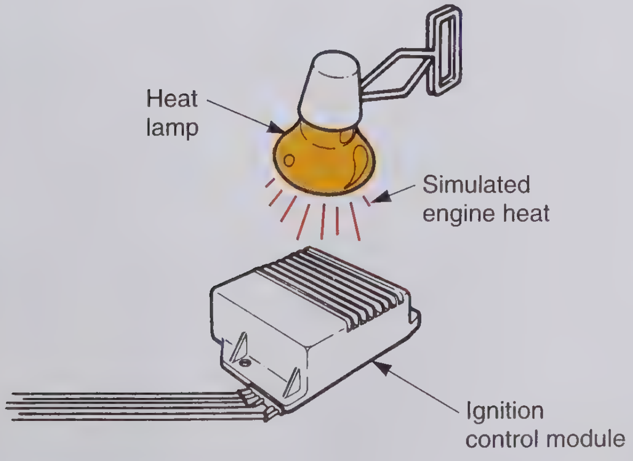

Figure 36-46. When testing an ignition control module, heat may help you locate an intermittent problem. Do not overheat the unit, or it could be damaged. (Ford)

Replacing an Ignition Control Module

Replacing an ignition control module is a simple task.

If the control module is mounted in the engine compartment or under the dash:

1. Carefully unplug the wiring harness.
2. Unbolt and remove the old unit.
3. Install the new unit.
4. Reconnect the wiring harness.

If the ignition control unit is mounted inside the distributor:

1. Remove the distributor cap.
2. Disconnect the wires leading to the module.
3. Remove the screws holding the module in place.
4. Remove the old control module.
5. Install the new unit according to service manual instructions.

In many cases, the bottom of the ignition control module must be coated with a special grease (silicone grease, dielectric heat-transfer compound, or heat-sink compound) before installation. This grease helps heat transfer into the distributor housing, protecting the module from overheating and circuit damage. See **Figure 36-47.**

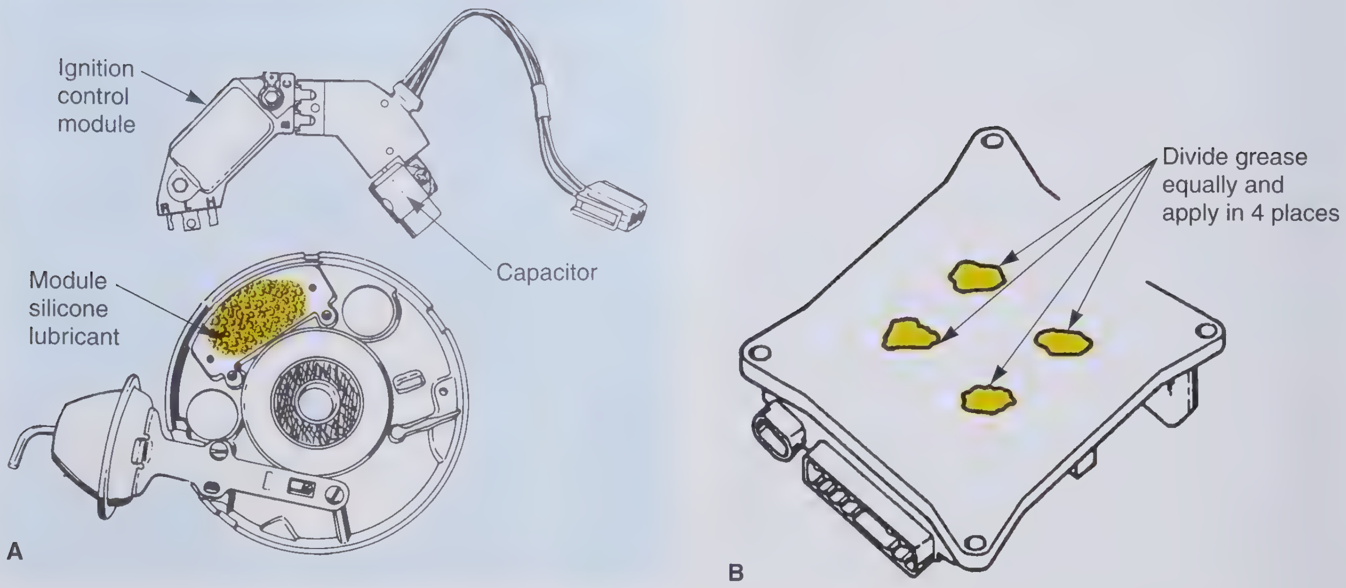
Make sure you have the correct ignition control module. The new control module may look identical to the old one, but it may have internal circuit differences. Even cars of the same year and make can require different ignition control modules.

Distributorless Ignition System Service

As discussed, many of the components used in a computer-controlled ignition system are similar to those found in older electronic or contact point systems. Testing procedures for these parts (spark plugs, secondary wires, ignition coils, etc.) have been covered earlier in this chapter. However, the computerized ignition system contains engine sensors and a computer, which make it more difficult to troubleshoot and service these systems.

In systems containing a coil pack that fires two spark plugs at the same time, a bad ignition coil will kill two cylinders. For example, if a four-cylinder engine has two ignition coils, one bad coil will make the engine run on two cylinders, producing a very rough idle. If two dead cylinders correspond to a specific coil, test that ignition coil.

Caution!
A computerized ignition system can be seriously damaged if the wrong wire is shorted to ground or if a meter is connected improperly. Always follow manufacturer's testing procedures.



Ignition control module
Module silicone lubricant
Capacitor
A
Divide grease equally and apply in 4 places
B

Figure 36-47. To prevent heat damage, silicone grease is sometimes applied to the ignition control module. A—When the ignition control module is in the distributor, apply silicone grease to the bottom of the module. Lubricant will help transfer heat out of the control module, ensuring proper operation. B—With larger control modules that are mounted on a heat sink, more grease may be needed. Follow the service manual instructions for the specific control module. (General Motors)

Note!
Refer to Chapter 19, *Computer System Service,* for more information on diagnosing computer-controlled ignition system problems. Normally, the computer system sensors (crankshaft position sensor, camshaft sensor, knock sensor, etc.) are common to both fuel and ignition systems.

Knock Sensor Service

A knock sensor is used to detect abnormal combustion or ping. When it "hears" pinging or knocking, it will retard ignition timing or lower turbo boost with the turbo waste gate. A bad knock sensor can upset ignition timing and affect turbocharger boost pressure. Many computers will store a trouble code if there is a potential problem with the knock sensor.

To check knock sensor operation, start the engine and allow it to reach operating temperature. Lightly tap on the engine block or a bracket with a wrench or small hammer. This will simulate pinging or knocking and should make the computer retard the ignition timing. The light taps should make the engine speed drop slightly. You might need to prop open the throttle to increase engine speed slightly so timing is advanced and will retard.

If tapping on the engine has no effect on timing and engine speed, you can check the sensor with a VOM or scope. Refer to the manual for recommendations. Remember to check the wiring leading to the knock sensor before removing or replacing the sensor!

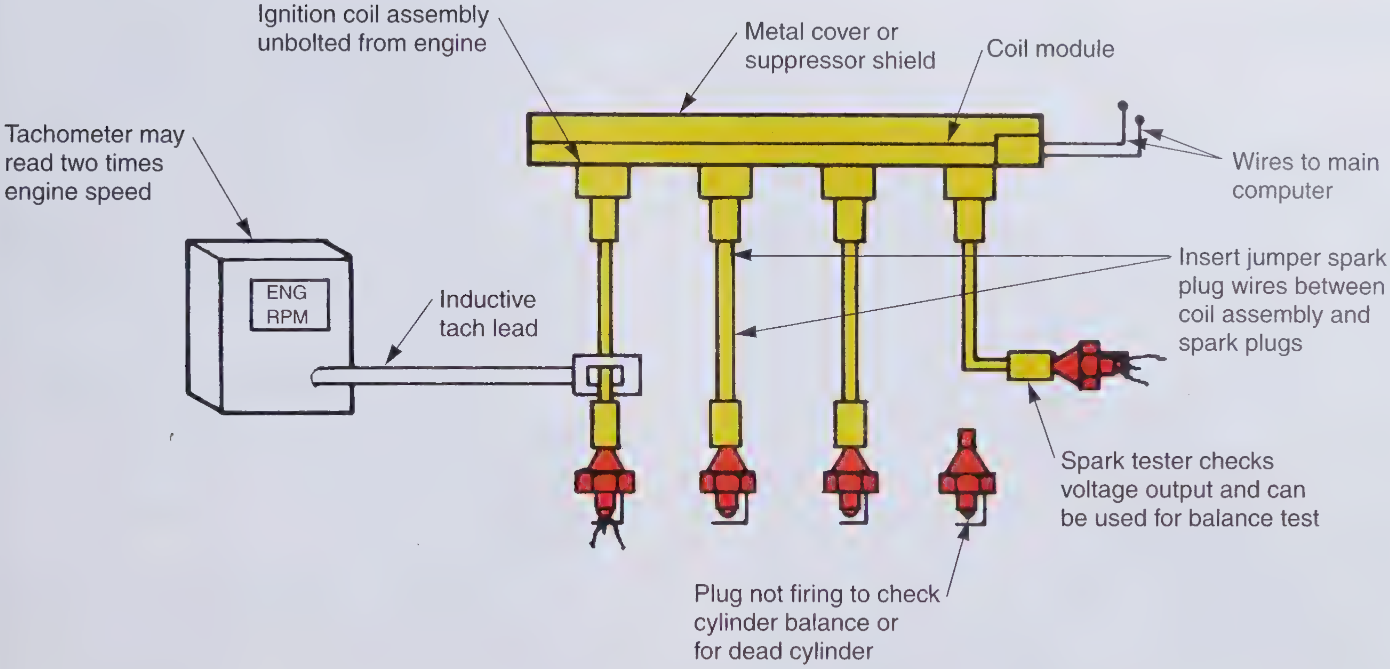
Direct Ignition System Service

The procedures for servicing a direct ignition system are similar to the procedures described for other types of ignition systems. The main difference is that you must test the ignition coil of the affected cylinder. For example, if the #1 spark plug is not firing, tests should be performed on the #1 ignition coil.

A direct ignition coil is tested like other ignition coils. Measure both primary and secondary winding resistance. Also make sure you are getting primary voltage to the coil.

Figure 36-48 shows some tricks for working on a direct ignition system. Remove the coil cover and connect conventional spark plug wires between the coil output terminals and the spark plugs. This will let you connect a timing light, an inductive tachometer, a spark tester, etc. to the system.

Note!
Several other textbook chapters contain information that will be useful when troubleshooting and testing an ignition system. Refer to the index as needed.



Ignition coil assembly unbolted from engine
Metal cover or suppressor shield
Coil module
Tachometer may read two times engine speed
Wires to main computer
ENG RPM
Insert jumper spark plug wires between coil assembly and spark plugs
Inductive tach lead
Spark tester checks voltage output and can be used for balance test
Plug not firing to check cylinder balance or for dead cylinder

Figure 36-48. Study these direct ignition system tests. The coil module can be unbolted and removed from the engine. Then, spark plug wires can be used to jump from the coil assembly to the spark plugs. This will let you connect an inductive tachometer to the engine. The tachometer may read two times actual engine speed if two plugs fire at once. You can also use a spark tester to check high-voltage output and short out each plug to make sure each cylinder is firing and lowering engine rpm. A scope or timing light can be connected to the engine with this setup.

Duff's Garage

Problem: Mrs. Kim drives her 1993 Honda Prelude into the shop complaining of an engine miss. "When this problem started, I took my car to my brother-in-law for repair," she said. "He replaced the spark plugs, the injectors, and the oxygen sensors, but my car still runs horrible."

Diagnosis: Duff questions Mrs. Kim about the exact nature of the problem. Mrs. Kim explains that the problem occurs all the time but seems to be worse in the morning or when it rains. Duff notes that water or moisture may be affecting engine operation and assigns the repair to the shop's master automobile technician.

Given the fact that high voltage tends to arc more readily under moist conditions, the technician decides that the first logical test would be to check for high-voltage leakage through the ignition secondary: spark plug wires, coil wire, and distributor cap. She checks to make sure that the plug wires are fully clipped onto the spark plugs and fully inserted into the distributor cap electrical terminals. She then drives the car into the shop and places fender covers over the sides of hood to block out light. She uses a spray bottle to mist water over the spark plug wires, ignition coil, and distributor cap. After starting the engine and allowing it to idle, the technician notices sparks arcing through the high-voltage ignition system wires and over the distributor cap to ground. Closer inspection reveals that the insulation on the secondary wires has deteriorated and the plastic distributor cap has carbon traces on it.

Repair: The technician removes the distributor cap and rotor. After inspecting the rotor and finding it to be in good condition, she reinstalls it. She installs a new distributor cap, making sure to reinstall the secondary wires in the proper terminals. Finally, she replaces the secondary wires, using the old wires as a guide. She replaces the wires one at a time, comparing the length of the new wires to that of the old ones. After changing the wires, the technician starts the engine and checks for a miss. The car seems to run fine, but as an added precaution, the technician again mists the engine compartment with water while looking for arcing. Not seeing any voltage leakage, she releases the vehicle to its owner.

Summary

- With late-model vehicles, a scan tool can be used to find troubles in the following ignition system circuits and components: crankshaft position sensor, crankshaft speed sensor, camshaft position sensor, knock sensor, ignition coil primary circuit, ignition coil secondary circuit, timing reference signal, other devices.
- If your scanner readout indicates a misfire, the engine has failed to properly ignite and burn its air-fuel mixture properly.
- A spark intensity test, also called a spark test, measures the brightness and length of the electric arc (spark) produced by the ignition system.
- A dead cylinder is a cylinder (combustion chamber) that is not burning fuel on the power stroke.
- A hand-held scope is usually a VOM combined with an oscilloscope in one housing. It is a handy tool for advanced troubleshooting of electrical-electronic problems.
- An engine analyzer contains several types of test equipment (oscilloscope, dwell meter, tachometer, VOM, etc.).
- An oscilloscope will precisely measure the operating voltages of an ignition system. It uses a television-type display screen to show voltage changes in relation to degrees of distributor or crankshaft rotation.
- Bad spark plugs can cause a wide range of problems, including misfiring, lack of power, poor fuel economy, and hard starting.
- Never remove a spark plug wire by pulling on the wire. Always grasp and pull on the boot.
- To read spark plugs, closely inspect and analyze the condition of each used spark plug tip and insulator.
- A wire feeler gauge should be used to measure spark plug gap.
- A faulty spark plug wire can have either a damaged conductor or deteriorated insulation.
- Problems often arise when a carbon trace (small line of carbon-like substance that conducts electricity) forms on the distributor cap, the rotor, or the ignition coil (coil pack).
- A bad pickup coil can produce a wide range of engine problems, including stalling, missing, no-start troubles, and loss of power at specific speeds.
- Dwell specifications vary with the number of cylinders in the engine and type of ignition system (contact point, electronic, or computerized).
- Fixed dwell means that the dwell time should remain the same at all engine speeds.
- Variable dwell means that the ignition module or engine control module alters ignition coil dwell time with engine speed.
- Current-limiting dwell means that the ECU sends high current through the ignition coil windings until a strong enough magnetic field is developed around the coil windings.
- Initial ignition timing is the spark timing set by the technician with the engine idling (no advance).
- Base timing is the ignition timing without computer-controlled advance.
- A timing light is sometimes used to measure ignition timing.
- Ignition timing is very critical to the performance of an engine. If the timing is off by even 2 or 3 degrees, fuel economy and power can drop considerably.
- Before removing a distributor, carefully mark the position of the rotor tip on distributor housing and the engine with a scribe or a marking pen.
- A faulty ignition coil may result in a weak spark, an intermittent spark, or no spark at all.
- A faulty ignition control module will produce a wide range of problems: engine stalls when hot, engine cranks but fails to start, engine misses at high or low speeds, etc.
- In systems containing a coil pack that fires two spark plugs at the same time, a bad ignition coil will kill two cylinders.
- A bad knock sensor can upset ignition timing and affect turbocharger boost pressure.

Review Questions—Chapter 36

Please do not write in this text. Place your answers on a separate sheet of paper.

1. Explain how to scan an ignition system and how scanning affects troubleshooting.
2. A(n) _____ _____ _____, also called a(n) _____ _____, measures the brightness and length of the electric arc produced by the ignition system. It provides a(n) _____ way of checking the condition of the ignition system.
3. Which of the following is commonly used to check the secondary output of an ignition system?
   (A) Voltmeter.
   (B) Ohmmeter.
   (C) Spark tester.
   (D) Ammeter.
4. Define the term "dead cylinder."
5. How do you find a dead cylinder without using special equipment?
6. What kinds of test equipment are usually found in an engine analyzer?
7. What does an oscilloscope measure?
8. Why should a technician "read" spark plugs?
9. Which of the following pertains to setting spark plug gap?
   (A) Wire feeler gauge.
   (B) Bend side electrode.
   (C) Space between center and side electrode.
   (D) All of the above.
10. When screwing a spark plug into the cylinder head, a socket, an extension, and a ratchet should be used to start the plug threads. True or False?
11. A faulty spark plug wire can have either a burned or broken _____ or deteriorated _____.
12. Explain both a resistance test and an insulation test of a secondary wire.
13. Define the term "carbon trace."
14. Describe how either an ohmmeter or a voltmeter can be used to test most distributor pickup coils.
15. Why is a nonmagnetic feeler gauge needed to set a pickup coil air gap?

ASE-Type Questions

1. An engine analyzer consists of all the following *except:*
   (A) VOM.
   (B) tachometer.
   (C) oscilloscope.
   (D) spark tester.
2. Which device will properly measure ignition system operating voltages over time?
   (A) Oscilloscope.
   (B) Dwell meter.
   (C) Spark tester.
   (D) All of the above.
3. Which of the following is *not* a problem that can be caused by bad spark plugs?
   (A) Misfiring.
   (B) High idle speed.
   (C) Hard starting.
   (D) Lack of power.
4. A properly burning spark plug should be:
   (A) blue.
   (B) black.
   (C) white.
   (D) brown.
5. Each of the following can be used to start spark plugs in their holes *except:*
   (A) a ratchet.
   (B) your fingers.
   (C) a spark plug socket.
   (D) a short piece of vacuum hose.
6. While conducting a secondary wire resistance test, Technician A states that wire resistance should be approximately 12,000 ohms per foot. Technician B says that resistance should be about 50k ohms (50,000 ohms) maximum for long spark plug cables. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. Which of the following is *not* a function of the distributor?
   (A) Sense engine speed.
   (B) Change ignition timing.
   (C) Maintain spark plug gap.
   (D) Distribute voltage to plug wires.

8. Most electronic ignition systems use this to sense trigger wheel rotation:
   - *(A) optical sensor.*
   - *(B) magnetic pickup coil.*
   - *(C) Hall-effect sensor.*
   - *(D) photo diode sensor.*
9. Which of the following is the ignition switch locking mechanism?
   - *(A) Tumbler.*
   - *(B) Steering column.*
   - *(C) Actuating rod.*
   - *(D) Suppresser shield.*
10. A car equipped with distributorless ignition enters the shop with two dead cylinders. Technician A says to check to see if the dead cylinders are operated by the same ignition coil in the coil pack. Technician B says to check for a bad crankshaft sensor. Who is right?
    - *(A) A only.*
    - *(B) B only.*
    - *(C) Both A and B.*
    - *(D) Neither A nor B.*

Activities—Chapter 36

1. Arrange to observe a technician at a tune-up shop or an auto dealership who is using an engine analyzer to diagnose ignition system condition. Ask the technician to explain what is being shown on the oscilloscope and other displays.
2. Demonstrate the use of a wire feeler gauge to measure the gap of a spark plug; then demonstrate the method used to set the gap to specifications.
3. Use a timing light to check the timing marks on two or three engines. Check your findings with the appropriate service manual to determine whether timing is “within specs.”

Ignition System Diagnosis		
Condition	**Possible cause**	**Correction**
No spark.	1. Breaker points defective or misadjusted (point ignition). 2. Distributor pickup defective or misadjusted (electronic ignition). 3. Defective condenser. 4. Discharged battery. 5. Faulty coil or primary circuit resistor. 6. No primary current to points. 7. Defective coil high tension lead. 8. Defective rotor and/or distributor cap. 9. Defective plug wires. 10. Moisture in distributor cap and on points. 11. Breaker plate not grounded. 12. Defective ignition control module. 13. Loose, corroded, or open electronic control module ground lead. 14. Loose, corroded, or disconnected primary connections. 15. Defective distributor electronic pickup. 16. Trigger wheel positioned too high. 17. Incorrect trigger wheel-to-pickup air gap. 18. Defective cam or crankshaft sensor.	1. Install new points. 2. Replace or adjust as needed. 3. Replace condenser. 4. Charge battery. 5. Replace coil or resistor. 6. Check ignition switch, coil, resistor, wiring. 7. Replace lead. 8. Replace cap and rotor. 9. Replace plug wires. 10. Dry cap and points. 11. Replace or tighten ground wire. 12. Replace ignition module. 13. Tighten, clean, or connect as needed. 14. Clean, cover with special, protective grease and shove firmly into distributor. 15. Replace pickup unit. 16. Reposition correctly. 17. Set correctly. Use nonmagnetic feeler gauge. 18. Replace defective sensor.
Weak or intermittent spark.	1. Breaker points defective (where used). 2. Defective condenser (where used). 3. Point dwell set incorrectly. 4. Discharged battery. 5. Loose or dirty primary wiring connections. 6. Weak coil. 7. Defective primary circuit resistor. 8. Burned rotor and cap contacts. 9. Defective resistance spark plug wires. 10. Insufficient system voltage. 11. Weak breaker spring pressure (point ignition only). 12. Worn distributor bushings or bent shaft. 13. Worn distributor cam (point ignition only). 14. Breaker arm sticking (point ignition only). 15. Loose spark plug wires. 16. Defective distributor electronic pickup. 17. Trigger wheel pin sheared. 18. Shorted primary wiring. 19. Loose wiring harness connectors.	1. Install new points. 2. Install new condenser. 3. Set dwell correctly. 4. Charge or replace battery. 5. Clean and tighten connections. 6. Replace coil. 7. Replace resistor. 8. Replace cap and rotor. 9. Replace resistance wires. 10. Adjust regulator. 11. Increase spring pressure. 12. Replace bushings or shaft. 13. Replace cam. 14. Free and lubricate bushing. 15. Clean and tighten connections. 16. Replace pickup. 17. Replace pin. 18. Replace wire and relocate. 19. Tighten connections.
Missing at idle or low speed.	1. Weak or intermittent spark at plugs. 2. Fouled spark plugs. 3. Spark plug gaps too narrow. 4. Improper plug heat range. 5. Damaged plugs. 6. Defective distributor electronic pickup. 7. Loose harness connections. 8. Discharged battery. 9. Coil polarity incorrect.	1. See *Weak or intermittent spark*. 2. Clean or replace plugs. 3. Adjust gaps to specifications. 4. Install proper heat range. 5. Replace plug or plugs. 6. Replace pickup unit. 7. Clean and tighten connections. 8. Charge or replace battery. 9. Reverse coil primary leads.

(Continued)

Ignition System Diagnosis

Condition	Possible cause	Correction
Missing during acceleration.	1. Weak spark.	1. See *Weak or intermittent spark.*
	2. Plugs damp.	2. Dry plugs.
	3. Fouled plugs.	3. Clean or replace plugs.
	4. Plug gap too wide.	4. Gap as specified.
	5. Damaged plug.	5. Replace plug.
	6. Incorrect trigger wheel-to-pickup air gap.	6. Set gap to specifications.
	7. Defective vacuum advance.	7. Repair or replace vacuum advance.
	8. Incorrect coil polarity.	8. Reverse coil primary leads.
	9. Crossfiring.	9. Rearrange ignition secondary wires.
	10. Weak ignition coil.	10. Replace ignition coil.
Missing during cruising and high-speed operation.	1. Weak spark.	1. See *Weak or intermittent spark.*
	2. Improper heat range plug (too hot).	2. Install proper heat range plug.
	3. Crossfiring.	3. Arrange wires properly. If needed, install new wires.
	4. Fouled plugs.	4. Clean or replace plugs.
	5. Plug gap incorrect.	5. Gap to specifications.
	6. Damaged plug.	6. Replace plug.
	7. Ignition timing incorrect.	7. Reset timing.
	8. Defective distributor.	8. Repair or replace distributor.
	9. Loose or corroded wire connections.	9. Clean and tighten connections.
	10. Defective spark plug wires.	10. Replace wires.
	11. Weak ignition coil.	11. Replace ignition coil.
Missing at all speeds.	1. Weak spark.	1. See *Weak or intermittent spark.*
	2. Fouled spark plugs.	2. Clean or replace plugs.
	3. Damaged plug.	3. Replace plug.
	4. Crossfiring.	4. Arrange wiring correctly and if needed, install new wires.
	5. Plug gap too wide or too narrow.	5. Adjust gap as needed.
	6. Plugs and/or distributor damp.	6. Dry distributor and plugs.
	7. Improper plug heat range.	7. Change to correct heat range.
	8. Defective distributor.	8. Repair or replace distributor.
	9. Defective spark plug wires.	9. Replace plug wires.
	10. Distributor trigger wheel pin sheared or missing.	10. Install new pin.
	11. Burned or corroded breaker points.	11. Replace and gap points.
	12. Defective condenser.	12. Replace condenser.
Coil failure.	1. Carbon tracking on tower.	1. Replace coil and wire nipple.
	2. Excessive system voltage.	2. Adjust voltage regulator.
	3. Oil leak in coil.	3. Replace coil.
	4. Engine heat damage.	4. Replace coil. Relocate or baffle against heat.
	5. Physical damage.	5. Replace coil.
Short spark plug life.	1. Incorrect plug heat range (too hot—burns).	1. Install correct (cooler) spark plug.
	2. Incorrect plug heat range (too cold—fouls).	2. Install correct (hotter) spark plug.
	3. Mechanical damage during installation.	3. Install correctly.
	4. Loose spark plug (overheats and burns).	4. Tighten plugs to proper torque.
	5. Incorrect plug reach (too short—fouls).	5. Install plugs with correct reach.
	6. Incorrect plug reach (too long—strikes piston).	6. Install plugs with correct reach.

(Continued)

Ignition System Diagnosis		
Condition	**Possible cause**	**Correction**
Short spark plug life. *(Continued)*	7. Worn engine—oil fouling. 8. Bending center electrode. 9. Detonation. 10. Preignition. 11. Lean mixture.	7. Switch to hotter plugs or overhaul engine. 8. Bend side electrode only. 9. Adjust timing. Change to higher octane gas and/or remove carbon buildup. 10. Remove carbon buildup, install valves with full margin, install cooler plugs. 11. Adjust air-fuel ratio.
Preignition.	1. Overheated engine. 2. Glowing pieces of carbon. 3. Spark plugs overheating. 4. Sharp valve edges. 5. Glowing exhaust valve.	1. Check cooling system. 2. Remove carbon. 3. Change to cooler plugs. 4. Install valves with full margin. 5. Check for proper tappet clearance, for sticking, and air leaks.
Detonation.	1. Ignition timing advanced. 2. Engine temperature too high. 3. Carbon buildup is raising compression ratio. 4. Low octane fuel. 5. Exhaust heat control valve stuck. 6. Excessive block or head metal removed to increase compression.	1. Retard timing. 2. Check cooling system. 3. Remove carbon. 4. Switch to high octane fuel. 5. Free valve. 6. Use thicker gasket, change head, or true warped head or block surface.

Many late-model vehicles are equipped with xenon headlamps. A xenon bulb is more than twice as bright as a comparable halogen bulb but consumes only two-thirds the power. (DaimlerChrysler)

37

Lights, Instrumentation, Wipers, and Horns—Operation and Service

After studying this chapter, you will be able to:

- Explain the operating principles of automotive light, wiper, and horn systems.
- Diagnose problems in light, wiper, and horn systems.
- Summarize automatic light and wiper systems.
- Replace burned-out bulbs.
- Explain how to aim headlights.
- Describe the safety practices to follow when working with light, wiper, and horn systems.
- Explain both analog and digital instrumentation.
- Summarize how to remove and service an instrument cluster.
- Correctly answer ASE certification test questions on light, instrumentation, wiper, and horn systems.

In this chapter, you will learn about the operation, basic testing, and repair of lighting, instrumentation wiper, and horn circuits, **Figure 37-1.** These are essential systems that perform important safety functions. They are installed on all passenger vehicles.

Figure 37-1. Light, wiper, and other major electrical systems are simple when studied separately. Note the location of the major components. (Honda)

After prolonged use, the lighting, instrument, wiper, and horn circuits may require repairs. Bulbs, switches, relays, motors, fuses, and wiring can fail. If you understand how these major parts function and follow basic testing techniques, each system is relatively easy to fix.

Lighting Systems

The ***lighting system*** consists of the components (fuses, wires, switches, and relays) that operate the interior and exterior lights on a vehicle. The exact circuit and part configurations will vary with each make and model of vehicle. However, the systems operate similarly.

Figure 37-2 shows a simplified drawing of a lighting system. As you will learn, actual vehicle lighting circuits are more complex than this.

The ***exterior lights*** typically include the headlights, turn signal lights, stoplights, parking lights, backup lights, and side marker lights.

The ***interior lights*** normally include the dome light, instrument lights in the dash, trunk light, and other courtesy lights.

Headlamp System

The ***headlamp system*** includes the battery, headlamp wiring, fuse panel, light switch, dimmer switch, headlamps (headlights), taillights, marker lights, and instrument lights. If the headlamps are concealed, the system also has either a vacuum or electric motor mechanism to operate the doors (flaps) over the headlamps.

The ***headlamp switch*** is an on/off switch in the dash panel or on the steering column. It controls current flow to the bulbs in the headlamp system. It may also contain a ***rheostat*** (variable resistor) for adjusting the brightness of the instrument panel lights. The rheostat can also be mounted in the dash. A vacuum switch may be added to the headlamp switch or in the circuit when vacuum doors are used over the headlamps. **Figure 37-3** shows a dash-mounted headlamp switch.

A ***multifunction switch*** is capable of controlling several circuits—headlights (bright and dim circuits) and turn lights simultaneously for example. Most late-model vehicles use multifunction switches. Look at **Figure 37-4.**

Most multifunction switches have a ***flash-to-pass feature,*** which energizes the high beams when the switch arm is pulled back. This lets the driver quickly warn traffic that he or she is going to increase speed and pass. As soon as the multifunction switch arm is released, the headlamps return to low beams.

The ***headlamp bulbs*** are high-intensity bulbs that illuminate the road during night driving or bad weather conditions. Headlight bulbs can have one or two elements. Two elements are needed to provide low and high beams. ***Low beams*** are used for driving in traffic and ***high beams*** for greater visibility when there is no oncoming traffic.

When current flows through the ***bulb element*** or ***filament,*** it gets white-hot and glows to produce light energy. The reflector and lens direct this light forward. See **Figure 37-5.**

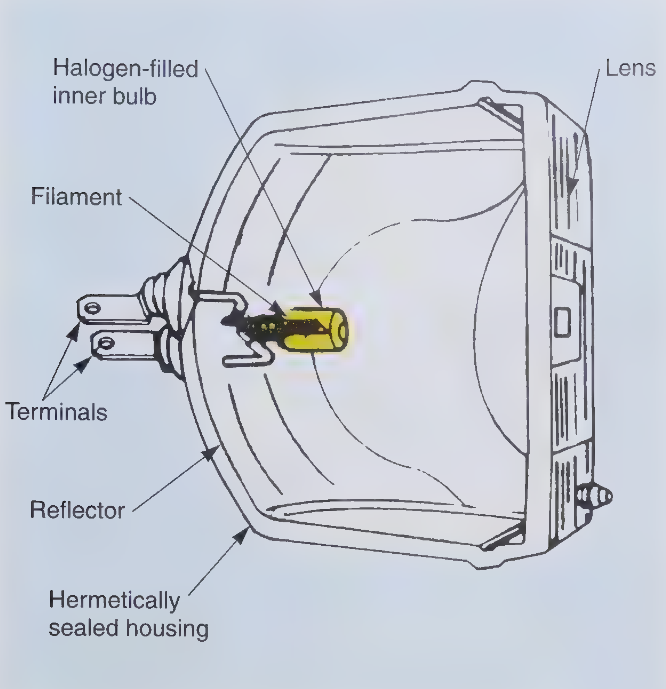

Figure 37-5. Sealed-beam lamp has an airtight glass housing around the filaments. This sealed-beam lamp has a small halogen inner bulb inside a glass lens. (DaimlerChrysler)

Sealed-beam headlamps have their filament(s) enclosed in a vacuum-sealed glass housing. There are two different types of sealed-beam lamps: number 1 and number 2. A *number 1 lamp* has only one lighting element. The *number 2 lamp* has two lighting elements (high and low beam). Vehicles with only two headlamps use two number 2 lamps to provide high and low beams. These have been phased out for smaller halogen headlamp bulb inserts.

Most late-model cars use *halogen headlamp bulb inserts,* which are small bulbs that fit into a larger plastic housing. The bulb is made of heat-resistant quartz that is filled with halogen gas to protect the filament from damage. See **Figure 37-6.**

Compared to a conventional headlamp, a halogen headlamp increases light output by about 25% with no increase in current draw. The halogen bulb is also whiter, which increases visibility. Halogen bulbs are rated in watts. A typical low-beam bulb is 45 watts, and a typical high-beam bulb is 65 watts.

Federal regulations limit how bright low-beam headlamps can be on public roads. The maximum brightness for low beams is 20,000 candle power. Brighter bulbs are available but should not be installed for use on public roads.

With a headlamp bulb insert, a *headlight lens* disperses the light beam in front of the vehicle and protects the bulb. This lens can be made of glass or plastic. Look at **Figure 37-6.**

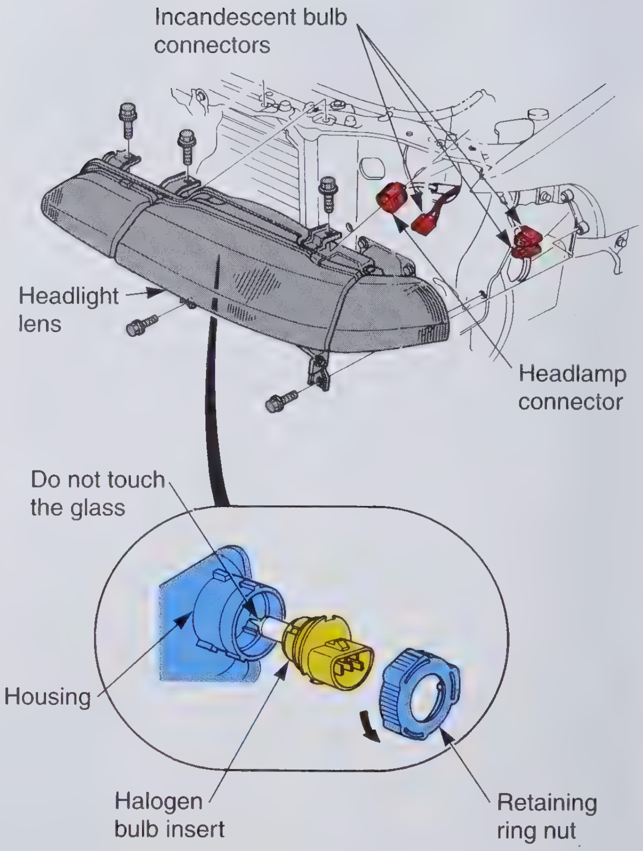

Figure 37-6. New vehicles commonly have halogen headlamp bulb inserts. The bulb insert installs in a plastic housing behind the lens. The lens and housing are not vacuum sealed. Note how the retaining ring nut locks the insert bulb into the housing. (Honda)

Tech Tip!
Always make sure you have the correct replacement lamp. Normally, a lamp number is stamped on the housing. If needed, take the old lamp to the parts house so it can be matched up.

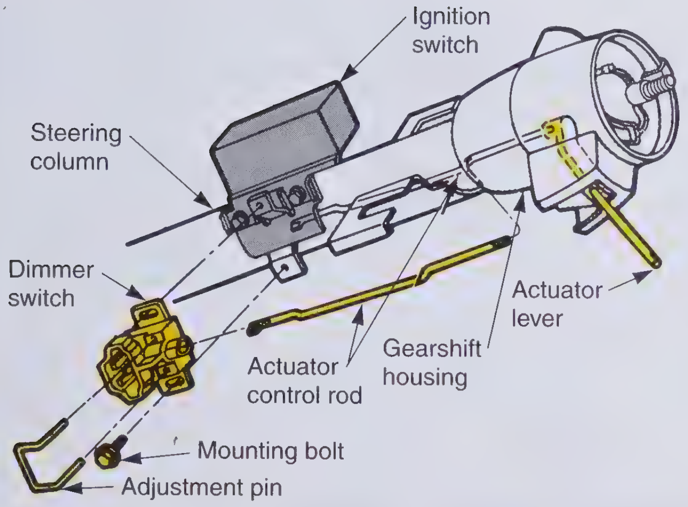
Headlamp Dimmer Switch

A *dimmer switch* controls the high and low headlamp beam function. This switch may be mounted on the steering column or floorboard. It simply controls which bulb filaments receive power. Refer to **Figure 37-7.**

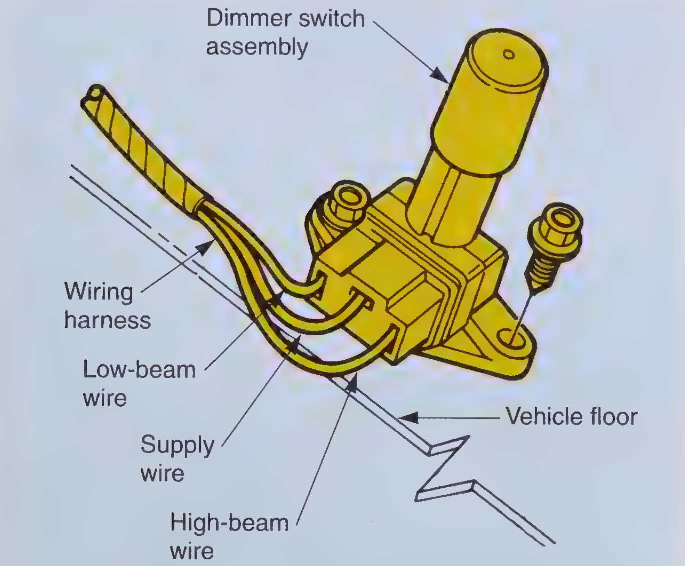
When the driver activates the dimmer switch, it changes the electrical connection to the headlamps. In one position, the headlamp high beams, or brights, are turned on. In the other position, the dimmer switch changes to low beam filaments for driving in traffic.

Automatic Headlamp Systems

An *automatic headlight dimmer system* uses a light sensor, amplifier, and relay to control the high and low beams. The system automatically dims the lights when



On steering column



On floor

Figure 37-7. Dimmer switch locations. (DaimlerChrysler and Ford)

detecting light from oncoming traffic. It switches to high beams when no oncoming light is detected.

The light sensor, or photosensor, may be mounted in the grille area or on the dash. The sensor produces a small amount of electric current when exposed to light. The amplifier uses this current to operate a dimmer relay. The relay changes the electrical connection from high beam to low beam automatically to keep the bright lights from blinding the occupants of oncoming vehicles.

Other variations of automatic control of the lighting system are available. Some turn the headlamps on when dark. Others (***auto-off headlamp system*** or ***delayed exit system***) automatically turn the headlamps off after a short delay period. By remaining lit, the headlamps increase visibility and security when walking away from the vehicle.

Daylight Running Lights

With ***daylight running lights*** (DRL), the headlamps are lit anytime the engine is running. This is a safety feature that makes the vehicle more visible. **Figure 37-8** shows a lighting system circuit diagram that includes DRL.

Turn Signal, Emergency, and Brake Light Systems

The turn signal, emergency, and brake light systems are normally considered separate circuits. However, they commonly use some of the same wiring, electrical connections, and lightbulbs. This is illustrated in **Figure 37-9.**

The lights in these systems are small incandescent bulbs. They can contain either one or two filaments. **Figure 37-10** shows two common types of bulbs for turn, emergency, stop, and backup lights.

Turn Signal System

The ***turn signal system*** consists of a fuse, turn signal switch, flasher unit, turn signal bulbs, indicator bulbs, and related wiring. When the steering column–mounted switch is activated, it causes the right or left side turn lamps to flash. Turn indicator lights in the instrument panel or on the fenders also flash.

The turn signal switch may be mounted in the center of the steering column, behind the steering wheel. A multifunction switch can also be used to control turn lights, horn, and dimmer switch. Look at **Figure 37-11.**

The ***turn signal flasher*** automatically opens and closes the turn signal circuit, causing the bulbs to flash. The flasher unit contains a temperature-sensitive bimetallic strip and a heating element. The bimetal strip is connected to a set of contact points and to the fuse panel.

When current flows through the turn signal flasher, the bimetallic strip is heated and bends. This opens the contact points and breaks the circuit. As the bimetal strip rapidly cools, it closes the points and again completes the circuit. This heating and cooling cycle takes place in about a second. The turn lights flash as the points open and close.

The turn signal flasher is frequently mounted on the fuse panel, **Figure 37-12.** However, it may be located somewhere else, such as under the dash. A shop manual will give the flasher location.

Tech Tip!
A turn signal flasher is designed to operate with a specific current draw. If you alter the load (add trailer lights, for instance), it can affect the operation of the flasher. Generally, if you increase current draw through the circuit, the flasher will blink more quickly. If you decrease current draw (one bulb burns out), it will slow or even stop the blinking action of the flasher.

Emergency Light System

The *emergency light system,* also termed *hazard warning system,* consists of a switch, a flasher unit, turn signal lamps, and related wiring. The emergency light switch is normally mounted on the steering column, **Figure 37-11.** It is usually a push-pull switch.

When the switch is closed, current flows through the emergency flasher. Like a turn signal flasher, the *emergency flasher* opens and closes the circuit to the lights. This causes the turn signals to flash. Oncoming traffic is warned of a possible emergency or hazard.

Brake Light System

The *brake light system* is commonly made up of a fuse, brake light switch, rear lamps, and related wiring. The brake light switch is normally mounted on the brake

pedal, as in **Figure 37-13.** Battery power is fed to the brake light switch from the ignition switch. When the brake pedal is pressed, it closes the switch and current flows through the wiring to the brake lights. This turns on the rear brake lights to warn traffic of the stop.

The brake light switch can also be located on the master cylinder. In these switches, hydraulic pressure from the brake system closes the switch to turn on the brake lights.

Note!
For more information on brake light systems, refer to Chapter 71, *Brake System Fundamentals,* and Chapter 72, *Brake System Diagnosis and Repair.*

Backup Light System

A ***backup light system*** typically has a fuse, gear shift- or transmission-mounted switch, two backup lamps, and wiring to connect these components.

The ***backup lamp switch*** closes the light circuit when the transmission is shifted into reverse. This illuminates the area behind the car. See **Figure 37-14.**

Illuminated Entry System

The ***illuminated entry system*** turns on the interior lights when you move the door handle or open the door. It allows you to see the key cylinders and the interior of the passenger compartment at night. Illuminated entry systems vary from simple to complex.

A simple illuminated entry system uses door-jam switches to turn on the interior lights. When a door is opened, it closes that switch to energize the lights.

More complex illuminated entry systems use an electronic control unit, various switches, and several interior lights. As shown in **Figure 37-15,** both door switches and

Footwell illumination light (passenger)

Figure 37-15. This illuminated entry system uses several switches (left) to signal the ECM (center), which operates the lights (right). When you pull up on the driver's door handle, it energizes the system. The lights fade in about ten seconds if no other switch is closed. (Lexus)

a driver's door handle switch energize the system. When one of the switches is closed, it signals the ECM. The ECM can then turn on the lights and time when they go off. Note that this circuit also illuminates the key cylinders and footwell in the passenger compartment.

Light System Service

Light system service involves changing burned-out bulbs, testing bulb sockets, checking fuses, finding shorted and open circuits, aiming headlights, and similar tasks. This section of the chapter will summarize the most important types of electrical tests and repairs performed on a car's lighting system.

Lamp Replacement

A ***burned-out bulb*** has the filament melted in half. Headlamps are usually held in place with small screws and a retaining ring. Halogen insert bulbs normally fit into the rear of the bulb housing. You must push and twist to install some headlamp bulb inserts. Sometimes a small ring screws over and secures the halogen insert. Spring clips can secure halogen fog lamp bulbs.

Figure 37-16 shows how several kinds of light assemblies fit together.

Most incandescent bulbs are housed in a lens. They are normally held in the socket by a spring and small dowels or a press fit. You may have to remove the lens or reach behind the housing to access the bulb. This is illustrated in **Figure 37-17.**

Always make sure you have the correct replacement bulb.

Caution!
Never touch the glass surface of a halogen bulb. The oil on your skin and the high operating temperature can make the glass shatter or shorten the bulb's service life. See **Figure 37-18.**

No-Light Problem

A ***no-light problem*** is a total failure of the light circuit or bulb. First, check to see if the bulb is burned out. Close inspection of the filament will show whether it has burned. If the bulb is good, check for power to the bulb socket.

Figure 37-19 shows how to check for current in a bulb socket. With the light turned on, there is a socket or circuit problem if the test light does not glow. If you do not have power to the socket, trace back through the circuit to find the open preventing current flow.

Flickering Light Problem

Flickering lights (lights go on and off) point to a loose electrical connection or a circuit breaker that is kicking out because of a short.

If all or several of the lights flicker, the problem is in a section of the circuit common to those lights. Check to see if the lights flicker only with the light switch in one position. For example, if the lights flicker only when the headlights are on high beam, you should check the components and wiring in the high beam section of the circuit.

If only one light flickers, the problem is in that section of the circuit. Check the bulb socket for corrosion. Clean the socket. Also, make sure the bulb terminals are

not worn. This could upset the electrical connection. If needed, replace the bulb socket and bulb.

Light Switch Problems

Light switch problems occur when a switch shorts closed or becomes open all the time. If shorted closed, the lights will always glow. If always open, the lights will not come on.

Figure 37-20 shows several of the types of switches used to operate lights and instrumentation systems.

To test a switch, use a test light or voltmeter to check for power going to and from the switch in the closed, or on, position. You can also disconnect the switch and test it with an ohmmeter, **Figure 37-21.**

This is door switch that must be squeezed lightly for removal from the door pillar. B—Connect an ohmmeter across the switch terminals. Activate the switch and the meter reading should go from almost zero to infinity. (Mazda)

Turn Signal Problems

If the turn signals do not flash, check for a burned-out bulb. Even one burned bulb will reduce current and prevent the flasher unit from functioning. A burned-out bulb is the most common cause of turn signal problems.

If both right and left turn signals do not work, check the fuse and flasher unit. The problem may also be in the turn signal or multifunction switch. It is prone to wear and failure after prolonged service. Something common to both sides of the circuit may be at fault if no bulb is coming on.

Figure 37-22 shows the basic steps for removing a multifunction switch.

Brake Light Problem

If none of the brake lights are working, something common to all the bulbs is at fault, such as the brake light switch or feed circuit. If only one bulb is not working, the bulb and its section of the circuit should be checked.

Other Light Circuit Problems

With other light circuit problems, you may want to refer to the wiring diagram for the specific make and model of vehicle. It will give wire color codes, connector locations, and other useful troubleshooting information.

Figure 37-23 is a wiring diagram from one service manual. Trace through the circuit and note the information given in the diagram.

Aiming Headlights

Aiming headlights involves adjusting the beams so they are directed to light the area in front of the vehicle. Headlights can be aimed using mechanical aimers, a wall screen, or leveling bubbles on the headlight housings. These methods ensure that the headlight beams point in the direction specified by the vehicle manufacturer.

Headlights aimed too high could blind occupants in oncoming vehicles. Headlights aimed too low or to one side could reduce visibility for the driver.

Before attempting to aim a vehicle's headlights, make sure the vehicle has about a half tank of gas and the correct tire inflation pressure. Remove extra cargo that could lower rear curb height and upset your headlamp adjustments. Only the spare tire and jack should be in the trunk. Some manfacturers recommend that someone sit in the driver and passenger seats while the lights are being aimed.

Headlight aimers are devices for pointing the car's headlamps in a specified position. To use aimers, follow

the instructions for the specific type of equipment. Some require a level floor. Others have internal leveling mechanisms to allow for an uneven shop floor. **Figure 37-24** shows the use of headlight aimers.

A ***headlight aiming screen*** is a series of measured lines marked on a shop wall for aiming a car's headlamps. One is shown in **Figure 37-25.** Note that lines are drawn on the wall at specific horizontal and vertical locations depending upon vehicle dimensions.

The car is normally located 25′ (7.6 meters) from the screen on a level floor. When the headlights are turned on, the highest points of light intensity (brightness) should be as shown in **Figure 37-25.** Aiming the low beams also aims the high beams. Refer to a service manual for added details.

Headlight adjusting screws are provided to alter the direction of the headlamp beams. One screw provides vertical adjustment. Another provides horizontal adjustment. Turn the screws until the aimer or screen show correct beam alignment. See **Figure 37-26.**

Headlight leveling bubbles are built into many late-model headlight assemblies to simplify headlight aiming, **Figure 37-27A.** You simply adjust the housing screws until the leveling bubble is centered in its indicator, **Figure 37-27B.**

Instrumentation

Instrumentation is used to inform the driver of various operating conditions—oil pressure, engine temperature, computer trouble codes, air bag system status, etc. Today's vehicles use a wide range of instruments, some simple and others complex. It is important that you understand the basics of instrumentation because it must be serviced in the field when problems develop.

Analog instruments use rotating needles or dials to indicate operating conditions. An analog speedometer, for example, uses a large needle that rotates around to show vehicle speed. An analog tachometer gives the same type of display for engine speed. See **Figure 37-28A.**

Digital instruments use various lights and electronic displays to show operating conditions. They do not have the mechanical parts, as analog instruments do. Look at **Figure 37-28B.** Digital displays are more complex than analog displays because an electronic control unit is needed to act as an interface between the sensor and the digital readout panel. Digital instruments can use vacuum fluorescent or liquid crystal displays.

Vacuum fluorescent displays are small glass tubes filled with neon or argon gas. They glow when electrically energized, making them very visible and easy to read.

Liquid crystal displays (LCD) are semiconductor panels that will pass light when electrically energized and block light when not energized. An LCD display is often backlighted to make it easier to read.

Instrument Cluster

The ***instrument panel*** is the general area of the dash behind the steering wheel that holds most displays. It is usually a removable assembly that includes the dash pad and the plastic covers over the front of the instrument cluster. The ***instrument cluster*** is the housing and clear plastic cover that holds the gauges, indicator lights, speedometer head, and bulbs.

To service an instrument cluster, remove the small screws around the outside of instrument panel. Often, you must remove a cover before accessing the screws that hold the instrument cluster in place. See **Figure 37-29A.**

Figure 37-28. Compare analog and digital instrument clusters. Both can use conventional incandescent bulbs and light-emitting diodes. A—An analog instrument cluster uses needles that sweep around gauges. Speedometer can be mechanical or electronic. B—A digital cluster uses vacuum fluorescent or liquid crystal displays to show conditions. (General Motors)

Before completely removing the instrument cluster, disconnect the wires and speedometer cable (if used). If you try to force the cluster out without disconnecting everything on the rear of the housing, the wiring and cluster could be damaged. Look at **Figure 37-29B.**

With the cluster out, it is easy to replace burned-out bulbs and inoperative gauges. **Figure 37-30** shows the rear of one make of instrument cluster. Note how the service manual illustration identifies the bulbs.

To replace gauges, you must open up the instrument cluster. Small screws hold the front glass or plastic lens to the housing. Remove these screws and remove the lens. The gauges may also be held in place by small screws through the rear of the cluster, **Figure 37-31.**

Tech Tip!

When handling the gauges and lens, keep fingerprints off everything. Dust will collect on the skin oil of fingerprints and cause customer complaints at a later date. Wipe everything clean before reassembly or wear clean gloves while handling instrument cluster components.

Dash Gauges

There are basically two types of gauges—balancing coil gauges and bimetal gauges. Both are commonly used and illustrated in **Figure 37-32.**

A ***balancing coil gauge*** uses two electric coils to cause needle deflection. The sending unit changes the current flow through the coils to deflect the gauge needle right or left using the magnetic field generated by each coil.

A ***bimetal gauge*** uses two dissimilar metals bonded together to cause gauge needle deflection. Generally, as current flow from the sending unit increases, the bimetal strip heats and defects more. Less current flow causes less bimetal arm bending and less needle deflection.

Sending units are used to control current flow to gauges. Many sending units are simply variable resistors. For example, with an oil pressure gauge, the sending unit is mounted on the engine to sense oil pressure. If oil pressure is low, the sending units resistance may be high to limit current flow to the oil pressure gauge. The gauge does not deflect to the right and the driver knows there is

low oil pressure. This same principle also applies to other gauges.

If a gauge is not working, check the sending unit first. The sending unit may not be working and may be preventing gauge operation. Special testers are available for checking the sending unit current going to the gauge. For example, the sending unit wire may need to be grounded. This should make the gauge deflect completely

to the right or left. If not, something other than the sending unit is at fault (wiring, fuse, gauge, connector).

Caution!
Do not ground a sending unit wire unless told to do so in a service manual. Some digital display circuits can be damaged by grounding the sending unit wire.

Note!
Gauges are also discussed in other applicable chapters. For example, the oil pressure gauge circuit is explained in the chapters on lubrication systems. The tachometer is summarized in the chapters on ignition systems. The engine temperature gauge is detailed in the chapters on cooling systems. Refer to the index for more information as needed.

B
Bimetal gauge

Figure 37-32. Compare the two types of gauges. Note the gauge voltage regulator in the circuit on the right. It maintains constant supply voltage to the gauge so it reads accurately. A—Coil gauge uses two coil windings to magnetically attract the indicating needle. With high current flow through the sending unit (low sending unit resistance), the left coil produces a stronger magnetic field, which moves the needle to the left. With low current through the sending unit (high sending unit resistance), more current flows through the coil on the right and the needle moves to the right. B—A bimetal gauge uses a thermostatic strip to move the indicator needle. With low current flow through the sending unit, the strip stays cool and does not bend, so the needle stays to the left. With higher current flow through the sending unit (low sending unit resistance), high current heats the bimetal strip and bends it. This bending action acts on the indicator needle to move it to the right.

Speedometers

There are two basic types of speedometers—mechanical and electronic. The electronic speedometer is becoming more common on modern vehicles. **Figure 37-33** compares simplified mechanical and electronic speedometers.

Mechanical Speedometers

A ***mechanical speedometer*** uses plastic transmission/transaxle drive gears, a metal speedometer cable, a cable housing, and a mechanical speedometer head. When the vehicle is moving, a drive gear on the transmission or transaxle output shaft turns a speedometer cable gear. This gears spins the metal speedometer cable in its housing. This rotating motion is transferred up to the dash to the speedometer head. Depending on rotating speed, the needle on the speedometer head is deflected to the right to indicate vehicle speed.

A dry speedometer cable will stick in its housing and cause the indicator needle to jump back and forth. The speedometer cable can also break, preventing speedometer operation. These are common problems with high-mileage vehicles.

To service a mechanical speedometer cable, disconnect the cable housing at the instrument cluster. You must normally depress a plastic latch that holds the cable housing to the cluster. Then, you can slide the speedometer cable out of the rear of the cluster.

To remove the speedometer cable, grasp and slide it out of its housing using a pair of pliers. If it is dry, wipe grease on the cable and slide it back into its housing. If it is broken, disconnect the cable housing at the transmission. You may need to use needle nose pliers to remove the small broken end from the transmission. Install a new speedometer cable of the original length.

If the speedometer needle does not return to zero when the vehicle is stopped, the speedometer head is usually bad. It should be replaced.

Electronic Speedometers

An ***electronic speedometer*** uses the vehicle speed sensor, an electronic control module, and an electronic or electric speedometer head or display. The vehicle speed sensor on the transmission or transaxle sends a signal representing road speed to the control module. The module can then produce an output signal to drive the digital display or servo motor in the speedometer head.

Electronic speedometers are now more common than mechanical speedometers. They are more dependable and consume less energy. Instead of spinning a heavy steel

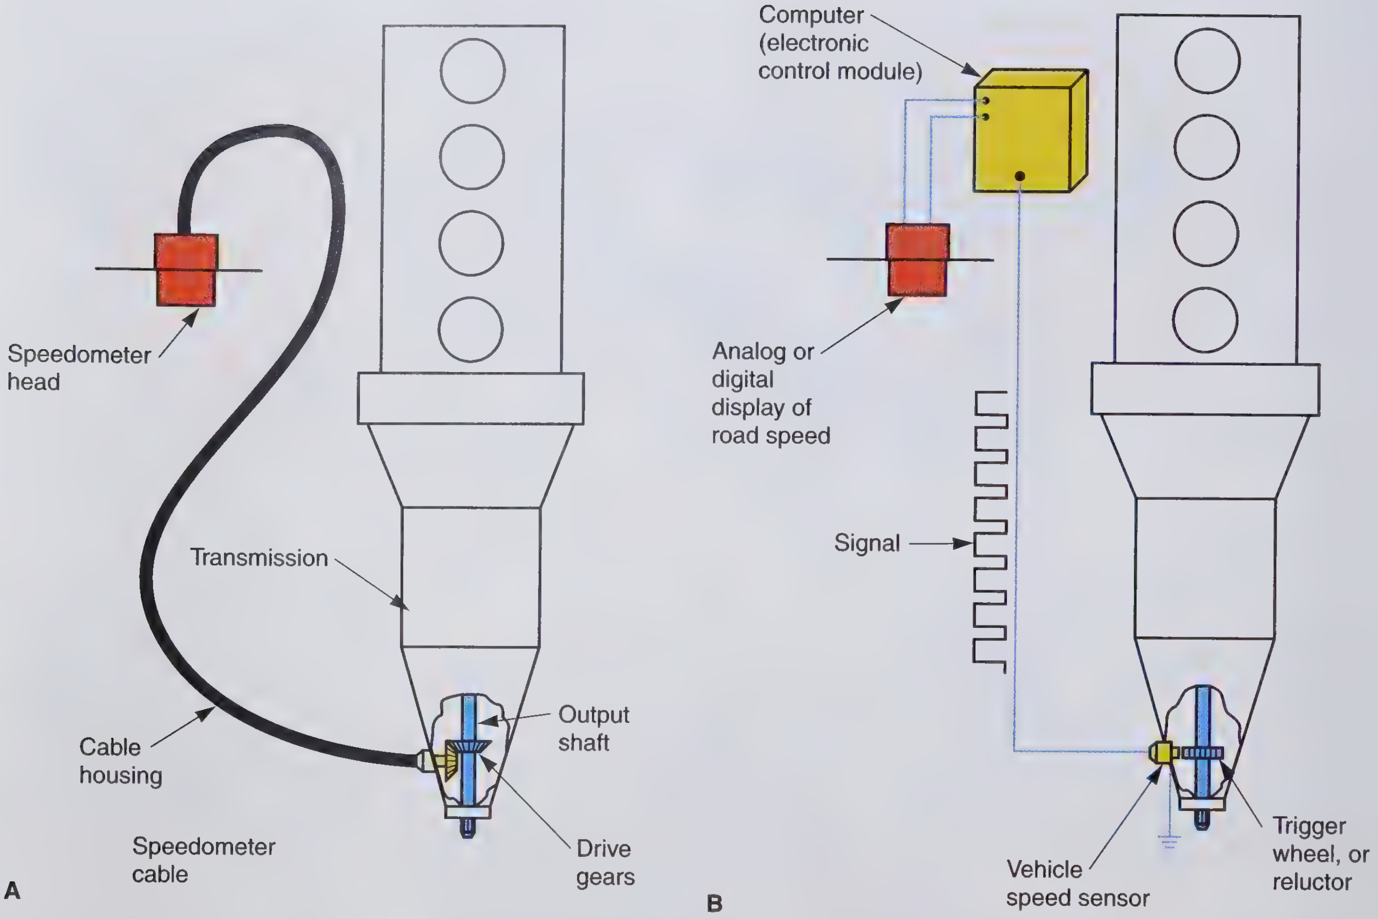

Figure 37-33. Compare mechanical and electronic speedometers. A—A mechanical speedometer is driven by small gears inside the transmission or transaxle. A gear on the output shaft spins another gear on the end of the speedometer cable. The cable spins inside the housing to transfer motion to the speedometer head to deflect the needle. B—An electronic speedometer commonly uses a vehicle speed sensor on the side of the transmission or transaxle. Trigger wheel or reluctor on the transmission output shaft sends a frequency signal into a sensor. The sensor signal is then used by the electronic control module to power the speedometer display.

cable, the speed sensor electrical signal is used to drive the electronic speedometer more efficiently.

Many electronic speedometers will only read up to a certain speed (85 mph or 145 km/h). Even though the vehicle can be driven faster, the ECM will not display a higher speed. This is normal on most vehicles.

Tech Tip!

When servicing an electronic speedometer, never change the ***odometer*** (mileage) reading. You must often reuse the old ***odometer chip*** (miniaturized circuit that stores mileage of the vehicle). The chip must be removed from the old cluster and installed in the new one. For more information on chip or PROM replacement, refer to Chapter 19, *Computer System Service.*

Figure 37-34 shows an electronic speedometer system that uses a speed sensor mounted near the transmission output shaft.

If an electronic speedometer fails to work properly, first check for stored trouble codes. Then, check for a good signal from the vehicle speed sensor. If the signal is reaching the ECM, check for a control signal going to the digital display. If only part of the display is working, you probably have a bad ***segment*** (part of display number or letter) and the display should be replaced.

Driver Information Center

The ***driver information center*** is a dash mounted keyboard-display for inputting and reading data about the vehicle. It allows you to send data to the instrumentation computer to find miles-to-empty, average fuel consumption, estimated time of arrival, and other information. The information center uses signals from many sensors to calculate this information. **Figure 37-35** shows how a digital display operates for several types of vehicle conditions.

Figure 37-35. This simplified illustration shows how different types of sensors can be used to indicate different conditions. The ECM converts sensor signals into output signals for displays. A—The engine is cold and sending unit internal resistance is high. The ECM shows a cold temperature readout. B—The engine is warmer and the sending unit resistance drops. The ECM uses a different amount of current flow to show the warmer engine temperature.

Driver information centers are very complex and vary with make and model. Always refer to the service manual for testing and repair directions.

Heads-Up Display

A ***heads-up display*** (***HUD***) reflects display information onto the windshield or a plastic dash panel for easier viewing. It compliments the conventional displays in the instrument cluster. The driver does not have to take his or her eyes off the road to view the HUD. One is shown in **Figure 37-36. Figure 37-37** shows how one type of reflective display operates.

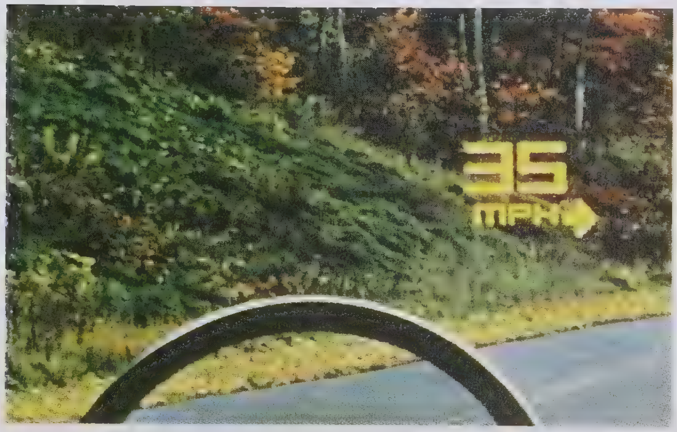

Figure 37-36. This heads-up display reflects images onto the windshield so readings are easy to see while driving. (GM Hughes Electronics)

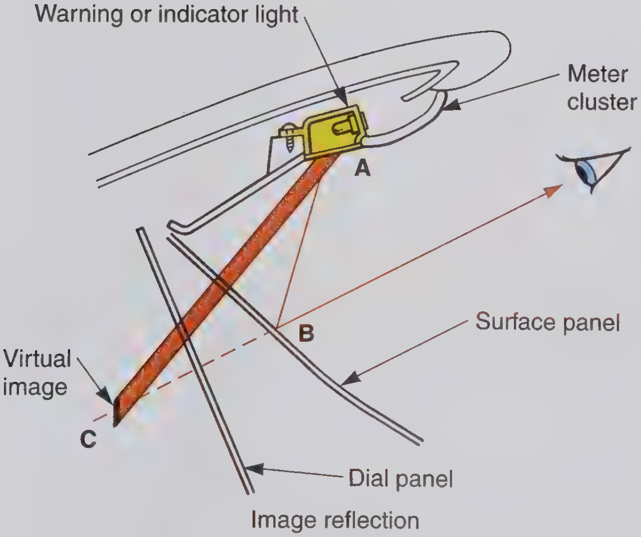

Figure 37-37. Drawing shows how an image is reflected onto a plastic surface on the dash panel. The LED at A is reflected to B before reaching the driver's eye. The driver actually views a virtual image at point C, a few inches behind the panel. (Lexus)

Windshield Wipers

A typical ***windshield wiper system*** is made up of a switch, wiper motor assembly, wiper linkage, wiper arms, wiper blades, and usually a windshield washer system. Either a fuse or circuit breaker protects the system. See **Figure 37-38.**

The ***windshield wiper switch*** is a multiposition switch that sometimes contains a rheostat. Each switch position provides a different wiping speed. The rheostat operates the delay mode for slow wiping action. A relay is frequently used to complete the circuit between the battery and the wiper motor. A typical windshield wiper-washer circuit diagram is shown in **Figure 37-39.**

The ***wiper motor assembly*** consists of a permanent-magnet motor and a transmission. The ***wiper motor transmission*** changes rotary motion into a back-and-forth wiping motion. The transmission is normally a set of plastic gears, an end housing, and a crank.

Figure 37-40 shows the parts of a typical wiper motor assembly. The drive crank on the transmission connects to the wiper linkage.

The ***wiper linkage*** is a set of arms that transfers motion from the wiper motor transmission to the wiper arms. The rubber wiper blades fit on the wiper arms. Refer back to **Figure 37-38.**

Windshield Washer

A ***windshield washer*** consists of a solvent reservoir, pump, rubber hoses, connections, and washer nozzles. As shown in **Figure 37-41,** the solvent reservoir, located in the engine compartment, holds a supply of water and solvent. When the washer switch or button is activated, the wiper motor and the washer pump turn on. Solvent is forced out of the reservoir and onto the windshield.

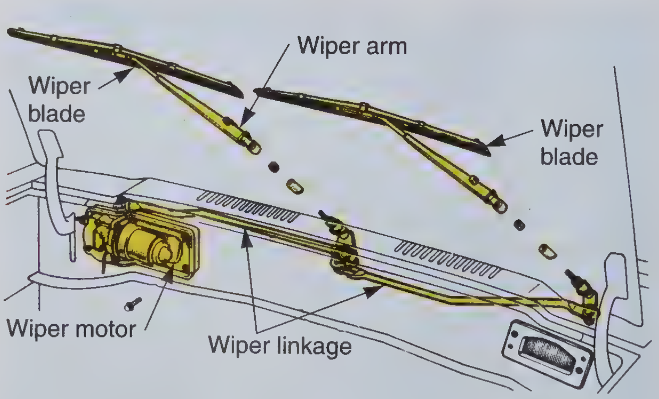

Figure 37-38. Study the basic parts of a typical windshield wiper system. (Toyota)

There are two common types of pumps used with windshield washer systems: a rotary pump and a bellows (diaphragm) pump. Most new cars use a rotary pump mounted in the solvent reservoir, **Figure 37-41.** A tiny electric motor spins an impeller, which forces the washer solution onto the windshield. A bellows pump is normally mounted on and powered by the wiper motor.

Rain-Sensing Wiper System

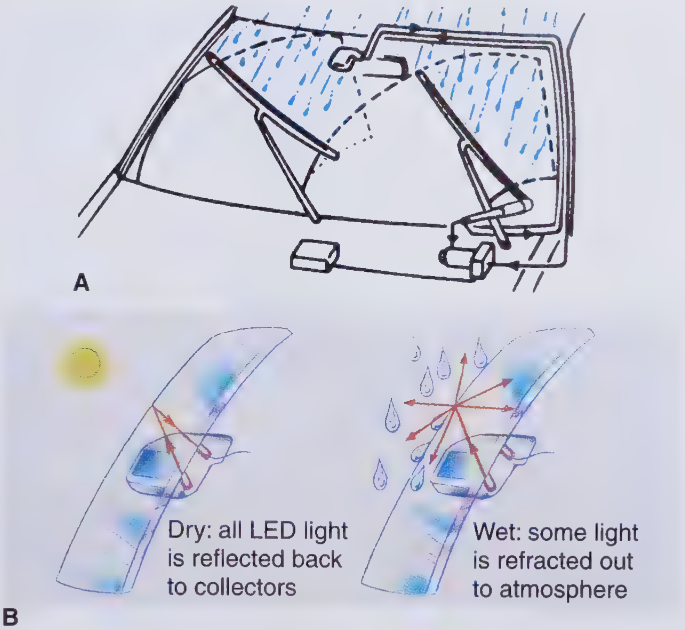
A ***rain-sensing wiper system*** automatically turns the windshield wipers on when water is detected on the windshield. The system uses light-emitting diodes and a light sensor or an infrared system to detect water. When water is on the windshield, less light is refracted back from the windshield to the light sensor. This allows an electronic control module to turn the wipers on to remove rain or snow. In heavy rain, the wipers wipe across the windshield more quickly. Manual override is also possible.

Figure 37-42 shows the basic operation of a rain-sensing wiper system.

Windshield Wiper Service

Windshield wiper blades should be inspected periodically. If they are hardened, cut, or split, replace them. **Figure 37-43** shows common wiper blade service methods.

With electrical problems in a wiper system, use a service manual and its wiring diagram of the circuit. First, check the fuses and electrical connections. If they are good, use a test light to check for power to the wiper motor.



A
Dry: all LED light is reflected back to collectors
Wet: some light is refracted out to atmosphere
B

Figure 37-42. Basic operation of a rain-sensing wiper system. A—A sensor on the back of the windshield and the ECM operate the wiper motor. B—When the windshield is clear, LED light is reflected back to a photo sensor and the wipers stay off. When the windshield has water or snow on it, some light is reflected away from the sensor. The sensor signal tells the ECM to turn on the wipers.

C—The arm can sometimes be removed by prying up as shown. D—Typical pattern for positioning arms on output shafts. Refer to a service manual for exact procedures. (DaimlerChrysler)

If power is being fed to the wiper motor, either the motor or transmission may be at fault. Before replacing the motor or transmission gears, make sure the motor is properly grounded. If power is not reaching the wiper motor, check the wiper switch and circuit connections for openings.

If the windshield washer does not work, check the fuse and connections. Use a test light to check for power going to the motor. If the test light does not glow (washer on), the wiper switch may be bad.

When working on a windshield wiper or washer system, always follow the exact recommendations given by the manufacturer. Systems and procedures vary from car to car.

Normally, the wiper motor must be replaced as a unit. The transmission gears are usually the only serviceable part in the assembly. An electric washer motor is also replaced when defective. It cannot be disassembled and repaired.

Horns

Today's ***horn systems*** typically include a fuse, horn button switch, relay, horn assembly, and related wiring. When the driver presses the horn button, it closes the horn switch and activates the horn relay. This completes the circuit. Current then flows through the relay circuit and to the horn.

Most horns have a diaphragm that vibrates by means of an electromagnet. When energized, the electromagnet pulls on the horn diaphragm. This movement opens a set of contact points inside the horn. This allows the diaphragm to flex back toward its normal position. Again, the points close and the diaphragm is pulled into the electromagnet. As a result, a rapid vibrating action is produced. A honking sound is transmitted out of the horn, **Figure 37-44.**

Horn Service

When a horn will not sound, check the fuse and connections, and test for voltage at the horn terminal. If a horn blows continuously, the horn switch may be bad. A relay is another cause of horn problems. The contacts in the relay could be burned, or they may stick together.

A ***horn current adjusting screw*** is sometimes provided on the horn to set the amp draw through horn. To adjust horn current, connect an ammeter between the feed wire and horn terminal. To prevent meter damage, be sure the ammeter can read more than 30 amps. See **Figure 37-45.**

Have someone sound the horn while you read the meter. If the current is not within specifications (typically

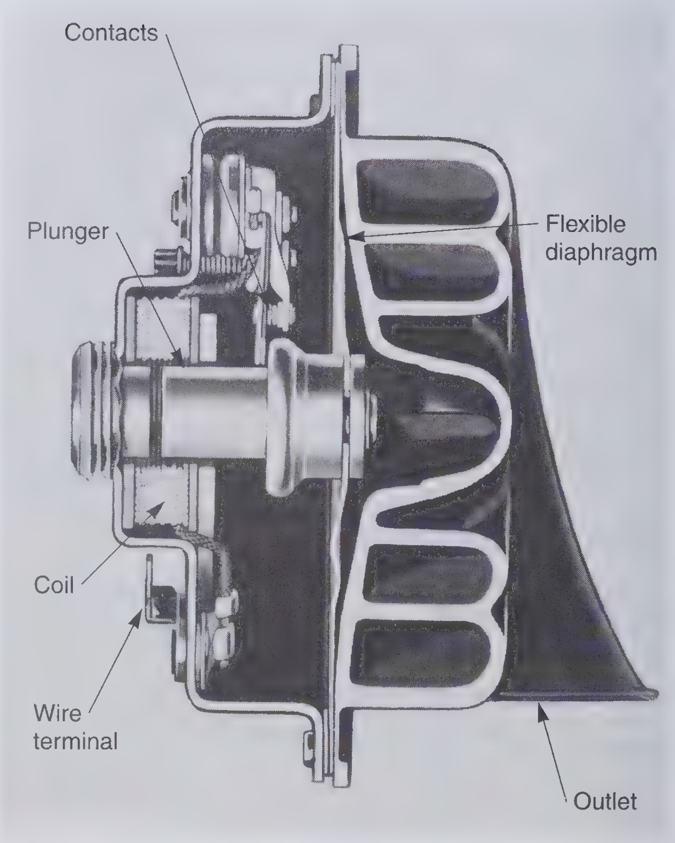

Figure 37-44. Horn contains a coil, points, and a flexible diaphragm. Coil and point action makes the plunger slide in and out of the coil. The plunger moves the diaphragm to produce horn sound. (Deere & Co.)

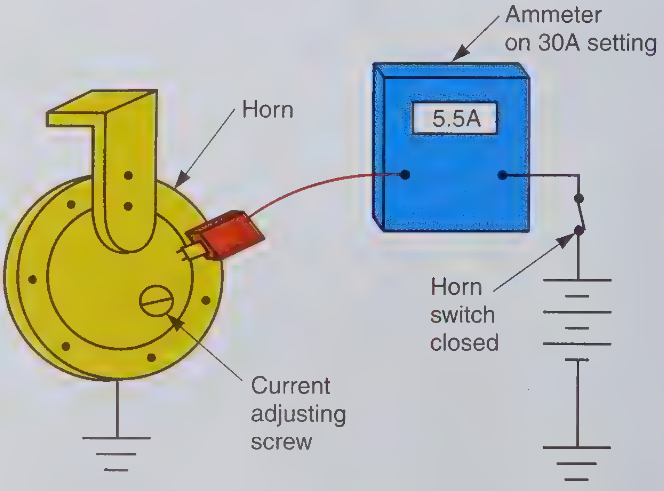

Figure 37-45. Some horns have an adjustment screw for setting the current draw through the horn. Connect an ammeter to measure the current draw. Press the horn button and adjust the screw for the specified current draw. If you cannot correctly adjust the current, check the supply circuit before replacing the horn.

4–5 amps), turn the amps screw on the horn until the meter reads properly. Also make sure you are getting adequate supply current/voltage and there is not a high resistance in the horn circuit. If you cannot get the horn to read within current specifications, replace it or isolate the circuit problem.

Refer to a shop manual when diagnosing and repairing a horn system. Although many horns are adjustable, they are not serviceable. Use your knowledge of the system and basic testing methods to locate troubles.

Finding Common Electrical Problems

There are several classifications of electrical problems. These are briefly covered in Chapter 8, *Basic Electricity and Electronics.* Problems include short circuits, open circuits, and high resistance in circuits. It is important for you to be able to quickly diagnose and locate these troubles when working on light, instrumentation, wiper, and horn circuits.

Short Circuit

A ***short circuit*** will show up as a blown fuse, a burned fusible link, or an open circuit breaker. A short circuit results when a ***hot wire*** (current-carrying wire) is touching ground. A wire's insulation may be cut, allowing the wire to touch body sheet metal, or a wire may be pinched between two parts, rupturing the insulation.

One way to locate a short circuit is to connect a test light across the blown fuse or open circuit breaker connections. This is shown in **Figure 37-46.**

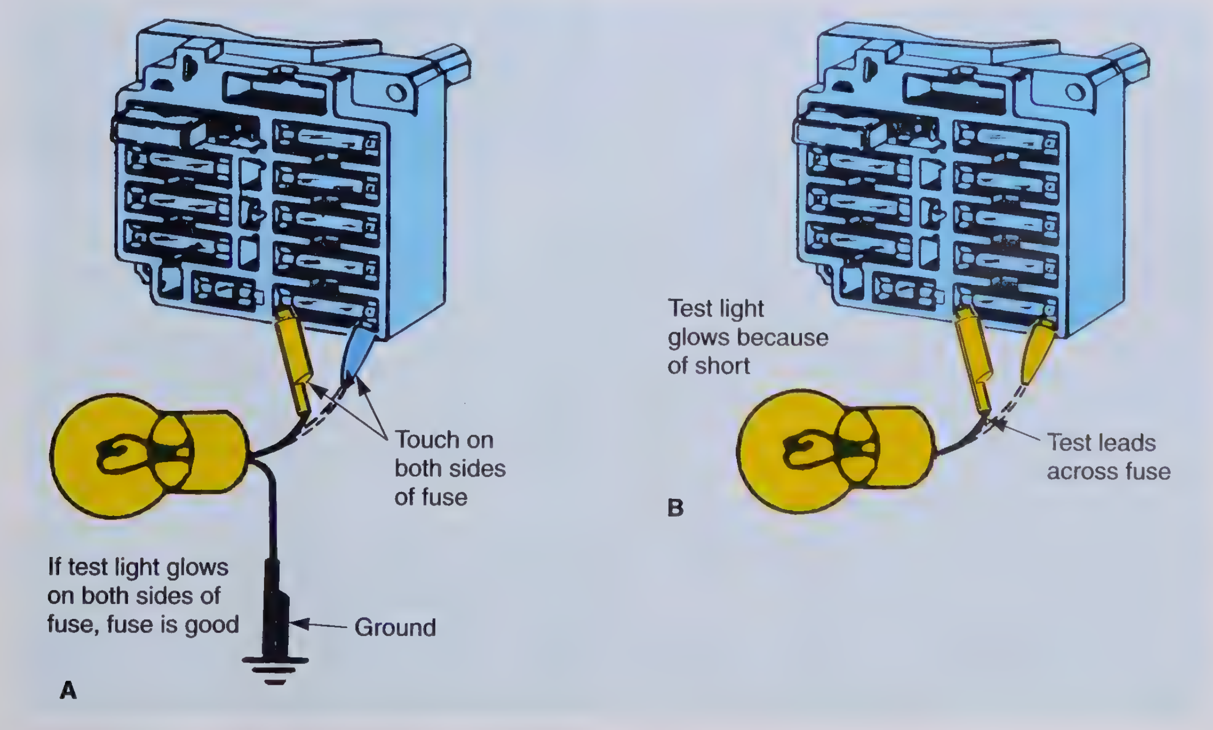
The test light will glow as long as there is a short in the circuit. Disconnect components or sections of the circuit while watching the test light. The test light will stop glowing when you remove the short from the circuit. Keep tracing the circuit (checking each wire connection and part) until the source of the problem is located.

After you have found and corrected the short, you can disconnect the test light and install a new fuse. Always install a replacement fuse with the same current rating as the blown fuse, **Figure 37-47.**

Caution!
Never install a fuse with a higher current rating to try to keep it from blowing. This can cause excess circuit current that could start an electrical fire.

Open Circuit

An ***open circuit*** will keep the electrical components in that section of the circuit from working. An open



Touch on both sides of fuse
If test light glows on both sides of fuse, fuse is good
Ground
A
Test light glows because of short
Test leads across fuse
B

Figure 37-46. A—To check a fuse, touch a test light on both sides of the fuse. It should glow on both sides if the fuse is not blown. B—To help find the short circuit that blows the fuse, connect a test light across the fuse as shown. The test light will glow if a short exists. Unplug wires and components while watching the test light. When the light goes out, you have disconnected the circuit section with the short. (Peerless)

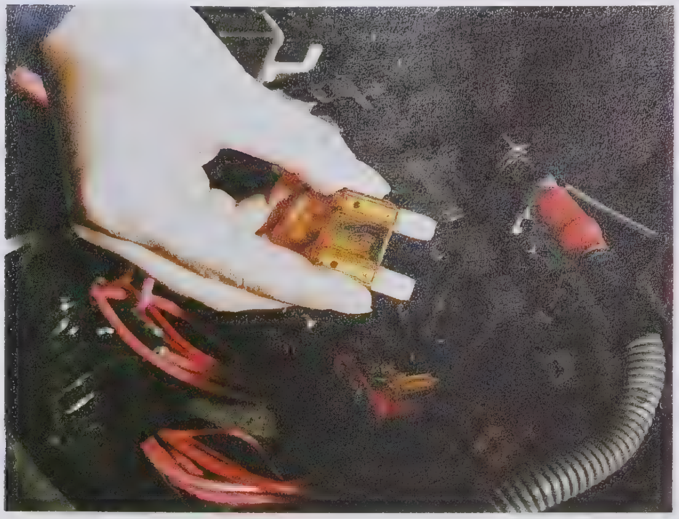


Figure 37-47. Always install a fuse with same current rating as the blown fuse. If the fuse still blows, you have short in the circuit.

circuit may be caused by a broken wire, a disconnected electrical connection, a bad switch, or another problem that prevents current flow.

An open circuit is easily located using a test light or a voltmeter, **Figure 37-48.** Start at each end of the circuit. Check for power at the supply (fuse panel). Then, go to the other end of the circuit and check for power at the load (a light socket, for example). If you have power at the fuse but no power at the load (socket), the open is between the fuse and the load. Trace the open by testing for power at the switch and at each electrical connection between the fuse panel and load.

Tech Tip!
If you probe through wire insulation, make sure you seal the hole in the insulation with liquid electrical tape. This will prevent moisture from entering the puncture in the insulation and possibly upsetting circuit operation later.

When there is no power at the fuse panel, the fusible link may be burned. If power is being fed to a closed switch but does not come out the switch, the switch or electrical connector is bad.

Use your understanding of system operation, a wiring diagram, and logical testing techniques to find an open circuit.

High Circuit Resistance

High resistance reduces the amount of current flowing through a circuit. For example, high resistance in a light circuit can cause the lamps to be dimmer than normal. To find a high resistance, measure the voltage drop across possible problem components.

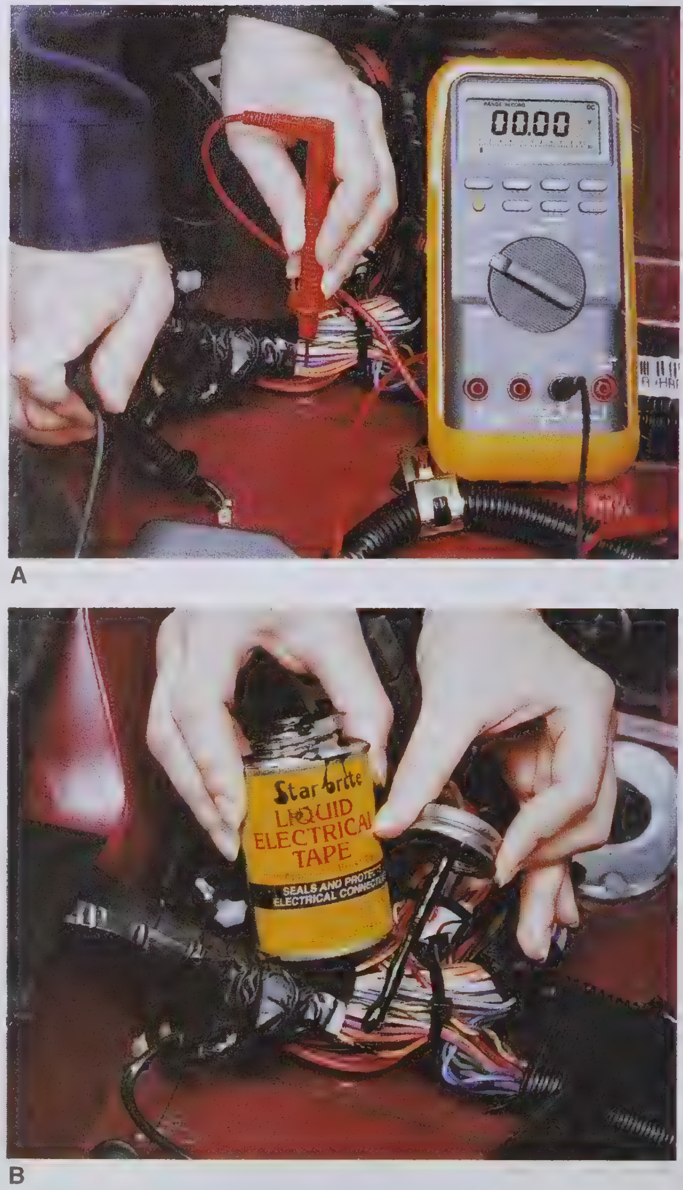

Figure 37-48. A voltmeter or test light will let you find open circuits quickly. A—Push pointed tip through wire insulation and ground the other lead. This will let you quickly check for voltage in different sections of the circuit. If you do not have voltage, that section of the circuit is open. B—When you probe through the wire insulation, always seal the hole with liquid electrical tape. This will keep out moisture that could corrode the wire and cause circuit problems later.

For example, if you suspect that a switch might be partially burned, measure the voltage drop across the switch. A high resistance (burned or corroded switch) will show up as a high voltage drop. This technique can also be used to check the internal resistance of other electrical components (electrical plug connectors, wires, and relays).

Typically, the voltage drop across an electrical conductor should not exceed 0.5 volts. Remember that this applies to wires, switches, and connectors, but not to electric motors, lightbulbs, or other loads.

Using Wiring Diagrams

Wiring diagrams are drawings that show the relationship of the electrical components and wires in a circuit. They are useful when an electrical problem is difficult to locate and correct.

Wiring diagrams normally give the following information:

- Wire color coding—special color markings on wire insulation for tracing wires through the vehicle.
- Component location—number-letter sequence around the border of the diagram for quickly finding parts in circuit.
- Wire splices and connections—where and how wires are joined together.
- Electrical symbols—simple drawings showing minor components in the circuit.
- Component drawings—simplified illustrations of major circuit components for easy location on diagram.

To use a wiring diagram, locate the parts being tested. Then, follow the lines that show where the wires go to the next component in the circuit.

If, for example, you are having trouble with a horn circuit, find the horn circuit diagram in a service manual. Trace the horn wires. You would then find a relay in the circuit between the horn and horn switch. It may be at fault.

Relay Problems

Relay problems usually result from worn, burned, or sticking contact points that prevent normal circuit operation. The small coil windings in a relay can also break, preventing the points from closing.

Many circuits are controlled by relays. Always look for relays in wiring diagrams and check them if power is not reaching a circuit on the output side of a relay.

Relays can be located almost anywhere on a vehicle—in the engine compartment, under the dash, on a fuse box, or under the rear seat cushion. The service manual will give relay locations for the vehicle being repaired.

To test a relay, first make sure a voltage signal is being fed to the relay windings. You can check this with a test light or voltmeter. If power is reaching the relay, check that the relay points are closing. Check for voltage leaving the closed relay points. If not, replace the relay, **Figure 37-49.**

Figure 37-49. Relays are a common source of trouble in all types of circuits. A service manual will give their locations and terminal connections for testing and replacement. This relay was found under the rear seat cushion.

Duff's Garage

Problem: Mrs. Jones walks into the office and says, "My headlights don't work! They work on high beams, but when I switch to low beams they go dead."

Diagnosis: Duff verifies the problem and turns the repair over to the shop's electrical technician. The technician removes the halogen bulbs and inspects the elements. Both bulbs are in good condition. He then uses a test light to check for voltage at the wire terminals in the bulb sockets. With the light switch in the high-beam position, voltage is present at the high-beam terminals of the sockets. However, when the switch is moved to the low-beam position, there is no voltage at the low-beam terminals. This narrows down the possible problem sources to the headlight switch or the wiring harness.

The technician uses the test light to check for power at the low-beam terminal of the light switch. Power is going to the switch, but it is not flowing through the switch to the low-beam circuit.

Repair: The technician replaces the multifunction switch on the steering column. He then checks to make sure all the vehicle's lights are working properly. He describes the problem and explains the repair to Mrs. Jones. He also shows her the old part.

Summary

- The lighting system consists of the components (fuses, wires, switches, and relays) that operate the interior and exterior lights on a vehicle.
- The headlamp system generally includes the battery, headlamp-related wiring, fuse panel, light switch, dimmer switch, headlamps, taillights, marker lights, and instrument lights.
- A multifunction switch is capable of controlling several circuits—headlights (bright and dim circuits) and turn lights, for example—simultaneously.
- Most late-model cars use halogen headlamp bulb inserts, which are small bulbs that fit into a larger plastic housing.
- A dimmer switch controls the high and low headlamp beam function.
- An automatic headlight dimmer system uses a light sensor, amplifier, and relay to control the high and low beams.
- The turn signal system consists of a fuse, turn light switch, flasher unit, turn lightbulbs, indicator bulbs, and related wiring.
- Light system service involves changing burned-out bulbs, testing bulb sockets, checking fuses, finding shorted and open circuits, aiming headlights, and other similar types of tasks.
- Aiming headlights involves adjusting the beams so they shine in the proper direction.
- Instrumentation is used to inform the driver of various operating conditions—oil pressure, engine temperature, computer trouble codes, air bag system armed, etc.
- Analog instruments use rotating needles on dials to indicate operating conditions.
- Digital instruments use various types of lights or electronic displays to show operating conditions.
- The instrument cluster is the housing and clear plastic cover that holds the gauges, indicator lights, speedometer head, and bulbs.
- A balancing coil gauge uses two electric coils to cause needle deflection.
- A bimetal gauge uses two dissimilar metals bonded together to cause gauge needle deflection.
- A sending unit or sensor is used to control current flow to the gauge.
- A mechanical speedometer uses plastic transmission/transaxle drive gears, a metal speedometer cable, a cable housing, and a mechanical speedometer head.
- An electronic speedometer uses the vehicle speed sensor, an electronic control module, and an electronic or electric speedometer head or display.
- A typical windshield wiper system comprises a switch, wiper motor assembly, wiper linkage, wiper arms, wiper blades, and usually a windshield washer system.
- Horn systems typically include a fuse, horn button switch, relay, horn assembly, and related wiring.

Review Questions—Chapter 37

Please do not write in this text. Place your answers on a separate sheet of paper.

1. What is the function of a rheostat?
2. How does a halogen headlamp differ from a conventional headlamp?
3. A dimmer switch can be located on the car's floor or on the steering column. True or False?
4. An automatic headlight dimmer system consists of a(n) _____ sensor, _____ , and _____ to control the high and low beams.
5. Explain the construction and operation of a flasher unit.
6. A vehicle has a problem causing the left headlight to flicker on and off. The right headlight works properly. The light seems to flicker when the car strikes bumps in the road. Technician A says that the light system relay may be bad. Vibration could be opening the points in the relay. The relay should be tested and replaced if needed. Technician B says that the problem involves just the left headlight section of the circuit. This technician suggests checking the headlamp socket and electrical connections to that bulb. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
7. One burned-out bulb cannot keep the turn signals from flashing on and off. True or False?
8. List four methods of aiming headlights.
9. Describe the operation of both mechanical and electronic speedometers.
10. List and explain the major parts of a windshield wiper system.
11. How does a rain-sensing wiper system work?
12. Explain the operation of a horn circuit.
13. Voltage drop across an electrical conductor should not exceed:
    (A) 0.1 volts.
    (B) 0.5 volts.
    (C) 0.10 volts.
    (D) 0.12 volts.
14. Wiring diagrams show:
    (A) wire color coding.
    (B) electrical symbols.
    (C) splices and connections.
    (D) All of the above.
15. The 12-volt circuit between a particular automotive turn signal switch and the turn signal lamps has a current flow of 2.3 amps. What is the approximate resistance in this circuit?
    (A) 5.22 ohms.
    (B) 7.35 ohms.
    (C) 2.67 ohms.
    (D) None of the above.

ASE-Type Questions

1. Which of the following is often used by automatic headlight dimmers to control beams?
   (A) Relay.
   (B) Amplifier.
   (C) Light sensor.
   (D) All of the above.
2. The right turn signals work but the left ones do not. Technician A says to check the flasher unit. Technician B says the turn signal switch could be bad. Who is right?
   (A) A only.
   (B) B only.
   (C) Both A and B.
   (D) Neither A nor B.
3. Each of these conditions should exist during a headlight aiming test *except:*
   (A) panel lights dimmed.
   (B) tires inflated correctly.
   (C) car has half a tank of gas.
   (D) spare tire and jack in trunk.
4. A headlight aiming screen is a:
   (A) veil covering headlights.
   (B) series of lines on shop wall.
   (C) transparent paper partition.
   (D) None of the above.

5. Which of the following is *not* a type of pump used with windshield washer systems?
   (A) *Rotary.*
   (B) *Bellows.*
   (C) *Rheostat.*
   (D) *Diaphragm.*
6. Generally, the *only* serviceable part of a windshield wiper motor assembly is the:
   (A) *wiper motor.*
   (B) *wiper blades.*
   (C) *wiper switch.*
   (D) *transmission gears.*
7. When correcting a horn system problem, Technician A says horns are not serviceable and can only be adjusted. Technician B says horns are serviceable but cannot be adjusted. Who is right?
   (A) *A only.*
   (B) *B only.*
   (C) *Both A and B.*
   (D) *Neither A nor B.*
8. A short circuit will show up as a:
   (A) *blown fuse.*
   (B) *burned fusible link.*
   (C) *open circuit breaker.*
   (D) *All of the above.*
9. There is a short in a light circuit that keeps blowing the circuit fuse. Technician A says to install a larger fuse to keep it from blowing. Technician B says to connect a test light across the fuse holder. By disconnecting parts and circuit wires, you can find the short when the test light goes out. Who is right?
   (A) *A only.*
   (B) *B only.*
   (C) *Both A and B.*
   (D) *Neither A nor B.*
10. The fog lights on a new car will not work. No power is reaching the bulb sockets. Technician A says to check the operation of the fog light relay shown on the wiring diagram. Technician B says the problem could also be the fog light switch. Who is right?
    (A) *A only.*
    (B) *B only.*
    (C) *Both A and B.*
    (D) *Neither A nor B.*

Activities—Chapter 37

1. Select a specific vehicle make and model that is at least two years old. Go to the automotive department of a discount or department store. Find the store's replacement lamp identifier system (it may be a book or large card or even a computer screen). Use it to identify the proper replacements for headlights, taillights, turn signals, brake lights, backup lights, and side marker lights (if used). List all the part numbers.
2. Demonstrate the proper procedure for checking headlight aiming, using marks on a wall. Show how to correct the aim of the lights, if necessary.
3. Find a wiring diagram for a car or truck, and make a photocopy. Use a brightly colored pencil or marker to trace the wiring that makes up the windshield wiper and washer circuit.

Headlamp Diagnosis

Condition	Possible causes	Correction
Headlamps are dim with the engine off or idling.	1. Loose or corroded battery cables. 2. Loose or worn alternator drive belt. 3. Charging system output too low. 4. Battery has insufficient charge. 5. Battery is sulfated or shorted. 6. Faulty lighting circuit. 7. Both headlamp bulbs defective.	1. Clean and tighten battery cable clamps and posts. 2. Adjust or replace alternator drive belt. 3. Test and repair charging system. 4. Test battery state-of-charge. Recharge or replace battery. 5. Perform load test. Recharge or replace battery. 6. Test and repair circuit. 7. Replace both bulbs.
Headlamp bulbs burn out frequently.	1. Charging system output too high. 2. Loose or corroded terminals or splices in circuit.	1. Test and repair charging system. 2. Inspect and repair all connectors and splices.
Headlamps are dim with engine running above idle.	1. Charging system output too low. 2. Faulty headlamp circuit. 3. High resistance in headlamp circuit. 4. Both headlamp bulbs defective.	1. Test and repair charging system. 2. Test and repair circuit as necessary. 3. Test amperage draw of headlamp circuit. 4. Replace both bulbs.
Headlamps flash randomly.	1. Poor headlamp circuit ground. 2. High resistance in headlamp circuit. 3. Faulty headlamp switch. 4. Loose or corroded terminals or splices in circuit.	1. Repair circuit ground. 2. Test amperage draw of headlamp circuit. 3. Replace headlamp switch. 4. Repair terminals or splices.
Headlamps do not illuminate.	1. No voltage to headlamps. 2. No ground at headlamps. 3. Faulty headlamp switch. 4. Faulty headlamp dimmer switch. 5. Faulty headlamp circuit.	1. Replace fuse. 2. Repair circuit ground. 3. Replace headlamp switch. 4. Replace headlamp dimmer switch. 5. Repair circuit.

Turn Signal Diagnosis

Condition	Possible causes	Correction
Turn signal flashes at twice the normal rate.	1. Faulty external lamp. 2. Poor ground at lamp. 3. Open circuit in wiring to external lamp. 4. Faulty contact in turn signal switch.	1. Replace lamp. 2. Check and repair wiring. 3. Repair wiring harness. Check connectors. 4. Replace switch.
Dash indicator lamp illuminated brightly; external lamp glows dimly and flashes at a rapid rate.	1. Loose or corroded external lamp connection. 2. Poor ground circuit at external lamp.	1. Tighten or replace connection. 2. Check and repair wiring.
Hazard warning system does not flash.	1. Faulty fuse. 2. Faulty flasher. 3. Open circuit in wiring to turn signal switch. 4. Faulty contact in turn signal switch. 5. Open or grounded circuit in wiring to external lamps.	1. Replace fuse. 2. Replace flasher. 3. Repair wiring. 4. Replace switch. 5. Repair wiring.

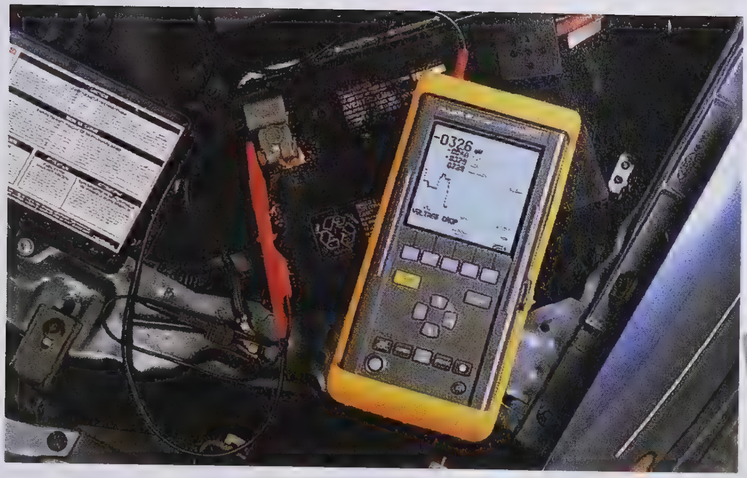
(Continued)

Turn Signal Diagnosis

Condition	Possible causes	Correction
Indicator lamp illuminates brightly, but external lamp does not light.	1. Open circuit in wire to external lamp. 2. Burned out lamp.	1. Repair wiring. 2. Replace lamp.
System does not flash on either side.	1. Faulty fuse. 2. Faulty flasher unit. 3. Loose bulkhead connector. 4. Loose or faulty rear wiring harness or terminals. 5. Open circuit to flasher unit. 6. Open circuit in feed wire to turn signal switch. 7. Faulty switch connection in turn signal switch. 8. Open or grounded circuit in wiring to external lamps.	1. Replace fuse. 2. Replace flasher. 3. Tighten connector. 4. Repair wiring harness. 5. Check repair wiring harness. 6. Check and repair wiring harness. 7. Test and replace switch. 8. Check and repair wiring harness.
System does not cancel after completion of the turn.	1. Broken canceling finger on turn signal switch. 2. Broken or missing canceling cam on clockspring.	1. Replace switch. 2. Replace clockspring.
External lamps operate properly; no indicator lamp operation.	1. Faulty indicator lamp in instrument cluster.	1. Replace lamp.

38

Sound Systems and Power Accessories



After studying this chapter, you will be able to:

- Describe the operating principles of a radio.
- Explain the basic difference between AM and FM radios.
- Diagnose basic sound system problems.
- Explain the operation and service of power windows.
- Sketch a rear window defogger circuit.
- Describe and repair a power lock system.
- Summarize the operation and testing of a speed control system.
- Describe safety practices that must be followed when working with electrical accessory circuits.
- Correctly answer ASE certification test questions on the service of sound systems and power accessories.

Many new cars are ordered from the factory with a wide array of power options. Options include premium sound systems, power seats, power windows, power door locks, and other convenience devices. These power options are very common; understanding their operating principles and service methods is important, even to the general technician.

After studying this chapter, you will be well-prepared to diagnose and repair optional power accessories. Remember that power accessory designs and circuits vary. Therefore, you must refer to a service manual to get specific diagrams and specifications for the exact system being repaired. This chapter will lay the groundwork so you understand manual instructions more clearly.

Note!
Air bag systems, automatic seat belts, and many other power systems are explained in other chapters. Refer to the index for more information as needed.

Sound Systems

A basic ***radio system*** consists of the antenna, radio (receiver-amplifier), power supply circuit, and speakers.

A basic operation of a radio is illustrated in **Figure 38-1.** The ***radio station*** sends out an electromagnetic signal from a large broadcasting tower. When this signal moves past the vehicle's antenna, tiny electrical modulations (fluctuations) are induced in the antenna.

The radio amplifies and alters these "weak" radio signals into stronger current pulses that operate the speakers. Each speaker diaphragm moves back and forth, producing air pressure waves. We hear these air pressure waves as sounds (voices or music).

A ***sound system*** is more elaborate than the basic radio system just described and often includes an AM/FM stereo radio, a tape player, and sometimes an amplifier, a sub-woofer speaker, a CD player, and a power antenna. These parts are shown in **Figure 38-2.**

Radio

A modern ***radio*** contains complex electronic circuits that receive and amplify the radio signal to operate the speakers. It also contains a ***tuner,*** which allows the driver to select different ***radio frequencies*** (stations).

There are two types of radio signals: AM (amplitude modulating) and FM (frequency modulating).

An ***AM radio*** is designed to pick up radio signals that vary in amplitude (strength). AM signals, which operate on a frequency of 530-1,610 kilohertz (kHz), are reflected off the ionosphere (upper atmosphere). This gives them a longer broadcasting range than FM signals.

An ***FM radio*** is designed to receive a radio signal that varies in frequency (fluctuating speed). The FM band is from 88-108 megahertz (MHz). Since the FM radio wave is not reflected off the ionosphere, it has a short broadcasting range (approximately 35 miles or 56 kilometers). FM radio is capable of producing stereo

(stereophonic) sound. A stereo uses at least two speakers and has different sounds coming from each speaker. **Figure 38-3** illustrates the differences between AM and FM radio signals.

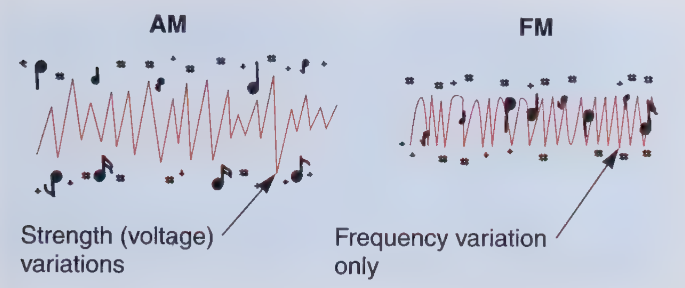

Figure 38-3. Note the difference between AM and FM signals. Radios must have circuitry that can "read" these different radio waves. (DaimlerChrysler)

Radio Service

If a radio fails to work, check its fuse. You may have external problems: a blown fuse, an open antenna or power supply lead, or bad speakers. Do not condemn the radio until all other problem sources have been eliminated. System designs vary; use the information in a service manual to diagnose radio problems.

Tech Tip!
Just because the lights in a radio are working does not mean the radio circuitry is getting power. Quite often, two power leads feed the radio. One lead is for the circuitry and the other is for the face lights. Make sure both leads are providing electrical power to the radio.

Figure 38-4 illustrates a wiring diagram for a sound system circuit. Trace the wiring from the battery through each component. A wiring diagram can be used to find difficult problems.

When the radio is found to be faulty, it should be removed and sent to an authorized repair technician. Various methods are used to secure radios. Some radios can be removed by simply removing the screws on the faceplate and pulling the radio out far enough to disconnect the wires and antenna lead. Others require partial dash disassembly for removal. In some cases, you may need to lie on the floor to remove a rear support bracket and the wiring.

If provided, an ***antenna trimmer screw*** should be adjusted when the radio has been removed for repairs or after antenna replacement. After reconnecting the radio, set the tuner to a weak station. Then, as shown in **Figure 38-5,** turn the trimmer screw until the weak station comes in as loud and clear as possible.

Antennas

An ***antenna*** picks up the broadcast signal and feeds it through the antenna lead to the radio. A very fine piece of wire mounted in the windshield glass can serve as the antenna. Other antennas are a metal ***mast*** (rod) mounted on the body.

A ***power antenna*** is a telescoping antenna that is extended and retracted by an electric motor. The electric motor turns a gear. The gear then operates a cable or slide mechanism on the antenna mast. Most power antennas go up and down automatically when the stereo is turned on or off. In some cases, however, a dash-mounted switch actuates the electric motor to move the antenna up or down. Look at **Figure 38-6.**

Antenna Service

If you suspect a bad antenna (no signal coming from antenna lead), connect a known good antenna to the radio. If the new antenna causes the stereo to work, replace the old antenna.

If a power antenna does not go up or down, check for power going to the motor. Use a test light or voltmeter. If power is reaching the antenna motor, the motor is probably bad. If you are not getting power, trace back through the circuit to find the problem.

Speakers

A ***speaker*** uses a permanent magnet and a coil of wire mounted on a flexible diaphragm to convert electricity into motion and sound. When current passes through the coil of wire, the resulting magnetic field pulls the coil and diaphragm toward the permanent magnet. Rapid movement of the speaker diaphragm causes pressure waves in the air. We hear these pressure waves as sound. Look at **Figure 38-7.**

The speakers may be mounted in the doors, dash, or behind the rear seat. AM radios normally have only one speaker in the top of the dash. FM stereo radios have two or four speakers.

Speaker Service

A faulty speaker will usually distort the sound of the radio. The speaker may rattle, especially when the volume is adjusted to a higher output level. A broken coil winding or terminal-to-coil wire can render the speaker inoperable.

Speakers are not usually repairable and should be replaced when defective. However, terminal-to-coil wires can sometimes be soldered when broken. The speaker mounting screws can also vibrate loose, creating a sound similar to a blown speaker. Tighten the speaker mounting screws and recheck audio quality.

Ohmmeter
Ω
Speaker terminals

Figure 38-8. To verify an internal problem with a speaker coil, check it with an ohmmeter. If shorted, resistance will be almost zero. If the windings are open, the ohmmeter reading will be very high. (Mazda)

Tape Player

A cassette ***tape player*** is often incorporated into the radio, **Figure 38-9.** As with radios, internal problems with a tape player require a specialized electronic technician. However, an automotive technician can perform external repairs: removing broken recording tape and cleaning the tape head.

CD Players

CD players, also termed ***compact disc players***, use a plastic disc to store and play music digitally. They are also a common option on today's vehicles. The CD player can be made as part of the stereo in the dash, or a remote unit located in the trunk, **Figure 38-10.**

Sometimes, a ***stereo amplifier,*** or "***power booster,***" is added to the sound system to increase volume without sound distortion, **Figure 38-11.** It can be located in the passenger compartment or trunk. It simply increases the electrical power available to drive the speakers. Without an amplifier, the stereo power transistors may go into thermal runaway when the stereo is played at high volumes.

Figure 38-9. When found to be defective, a receiver is often sent out to a specialty electronics shop for repairs.

Thermal runaway occurs when a transistor is driven too hard (too much output current is controlled by the transistor).The output of the transistor will fluctuate as the transistor's thermal capacity is exceeded, and severe distortion will be heard from the speakers. With enough thermal runaway, the transistor will fail.

When troubleshooting a sound system, determine which sections of the system are working and which are not. For example, if the radio and tape player work but the CD player does not, check the part of the circuit related only to the CD player. If tests find something wrong with the CD player, send it to a specialized shop for repairs.

Tech Tip!
Steering wheel touch controls (switches mounted on steering wheel) are sometimes provided for the stereo, air conditioning, speed control, and other systems. Keep the steering wheel controls in mind when troubleshooting problems with these systems.

Radio Noise

Radio noise is undesired interference or static (popping, clicking, or crackling) obstructing the normal sound of the radio station. Radio noise is commonly caused by a bad antenna, an open or shorted noise suppressor (capacitor), a bad spark plug wire, a faulty radio, or other

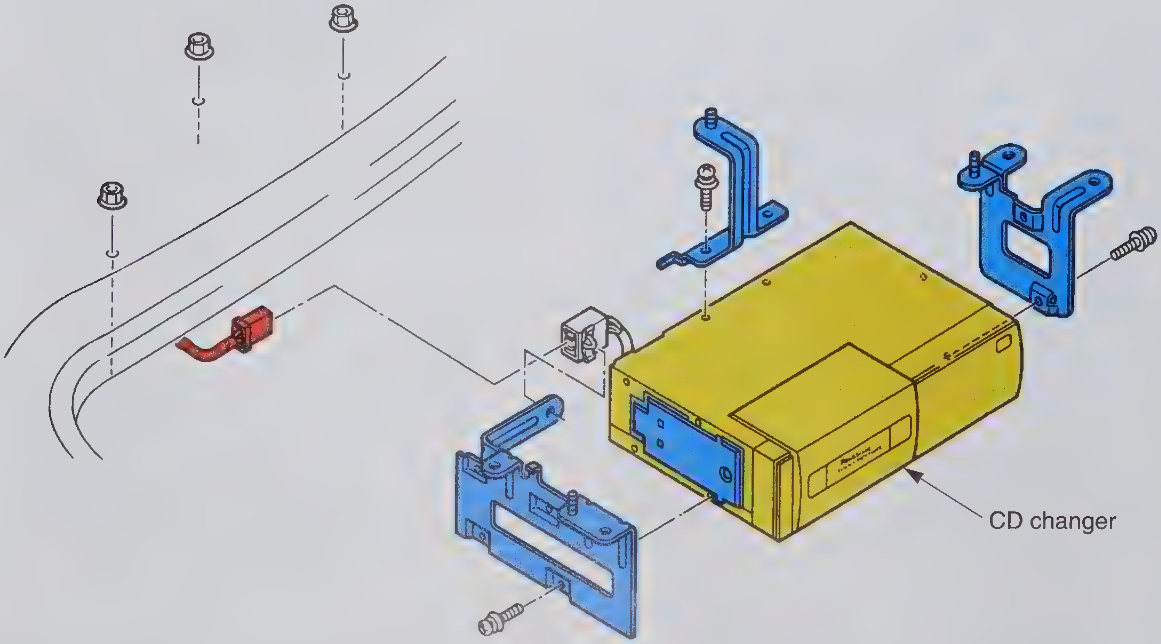

Figure 38-10. A CD changer normally mounts in the trunk. Check for stuck CDs, dirty heads, and power feed problems caused by bad wiring before sending the unit out for repairs. (Mazda)

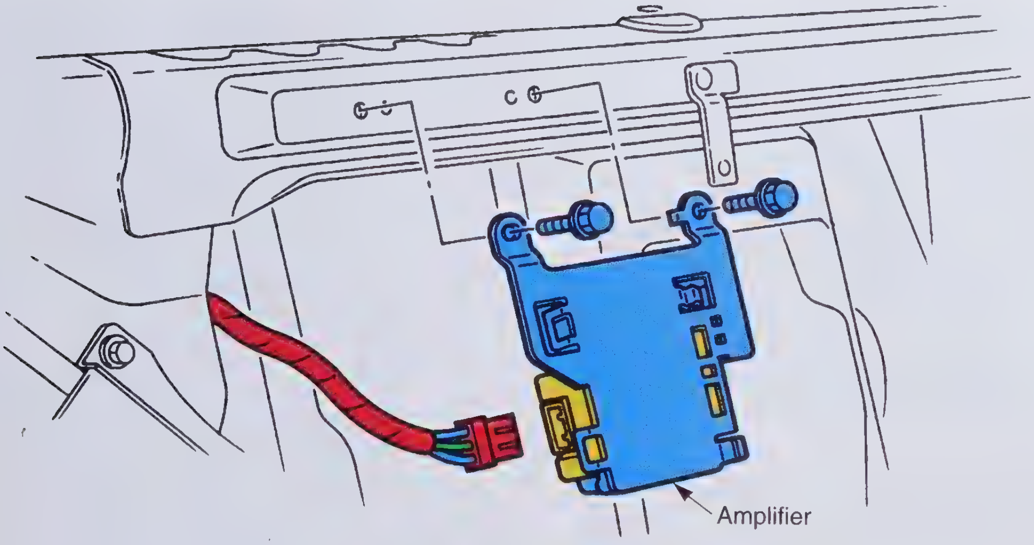

Figure 38-11. A stereo amplifier may be located in the trunk or under a seat. (Mazda)

problems. If the stations are too far away, noise will also interfere with the signal.

Study the sound of the radio noise to determine its source. For example, a low-pitched clicking that changes with engine speed may be caused by the ignition system (open spark plug wire). A high-pitched whirring sound that also changes with engine speed could be from the electrical system (bad capacitor or alternator diode), **Figure 38-12.**

One of the first parts to check when radio noise is present is the antenna. Plug a known good antenna into the radio. Ground the antenna base and note any changes in radio output. If the noise is eliminated, the old antenna is faulty. If the noise remains the same, check the noise suppressors.

Noise suppressors are capacitors that absorb voltage fluctuations in the car's electrical system. They result in smoother dc current entering the radio, which reduces radio noise.

Noise suppressors can be located at the alternator, voltage regulator, ignition coil, distributor, and heater blower motor. All these components can produce voltage fluctuations and noise. Refer to a service manual for exact suppressor locations.

A clip-on capacitor can be used to test noise suppressors, **Figure 38-13.** Connect the test capacitor across or in place of the suppressor. If the radio static is reduced, install a new suppressing capacitor.

Figure 38-12. Two common locations for radio noise suppressors. (DaimlerChrysler)

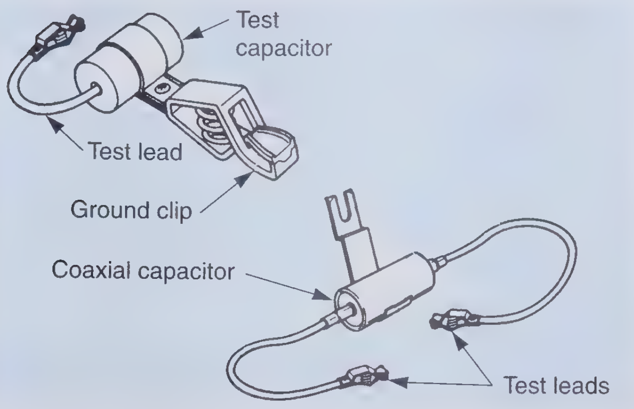

Figure 38-13. Test capacitors can be used to check existing noise suppressors. If radio static quiets when the test unit is connected to the circuit, the old capacitor is bad or there may be other electrical problems. (Pontiac)

Power Seats

Power seats use several switches, electric motors, and drive assemblies to change the seat positions. The power seat switches can be on the inner door panels or on the sides of the seats. The power seat motors and drive assemblies can be under or in the seats, **Figure 38-14.**

When activated by a switch, the reversible dc motors operate a gear mechanism. The gear mechanism changes the rotating motion of the motor armature into a linear motion that positions the seat. Most power seats have more than one seat motor. Power is sometimes transmitted from the power seat motors to the tracks or adjustment mechanisms by steel cables inside metal housings. **Figure 38-15** shows how a simple power seat circuit can create several seat positions.

Figure 38-16 is a typical wiring diagram for a power seat system. Trace the wiring from the seat position sensors, power seat module, switches, power seat motor, and other components.

Memory seats use a small computer, or module, to "remember" seat positions for several people. Some computer memory systems are networked and will remember not only seat positions but also steering wheel tilt positions, rearview mirror settings, and even electronic suspension settings for each driver.

Tech Tip!
As a safety feature, many power seat memory systems will only work with the transmission shift lever in park or neutral. They are wired to the neutral safety switch. Make sure the transmission is in park (automatic transmission or transaxle) when checking memory seat operation.

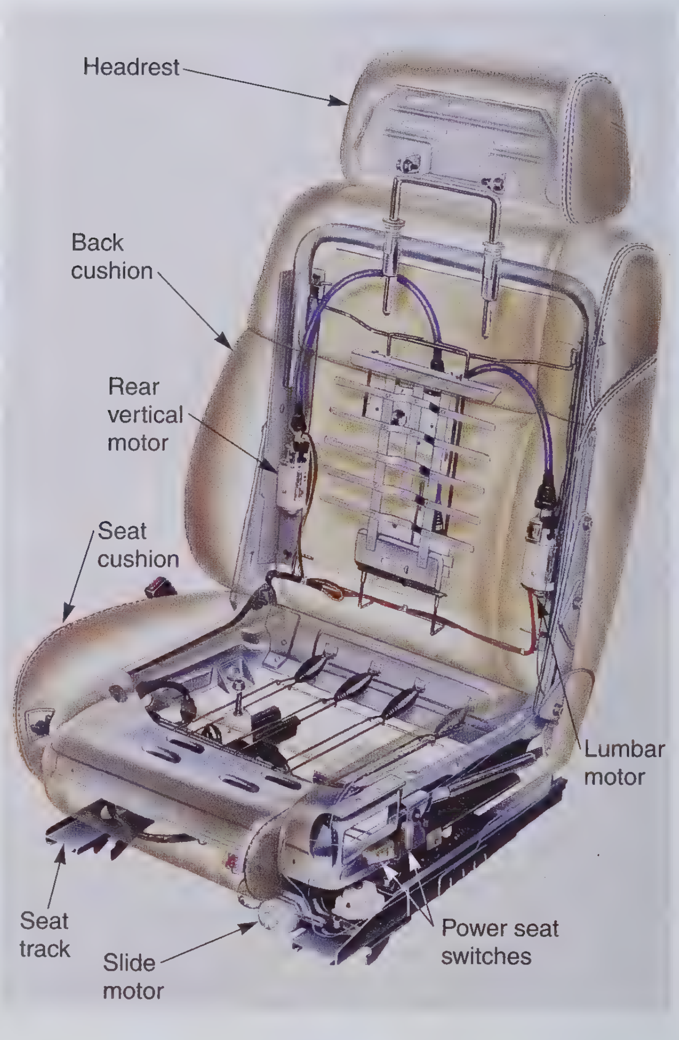

Figure 38-14. Cutaway view of a power seat shows the seat motors, transmission cables, tracks, and other parts. Seat removal may be needed to service seat motors. (General Motors)

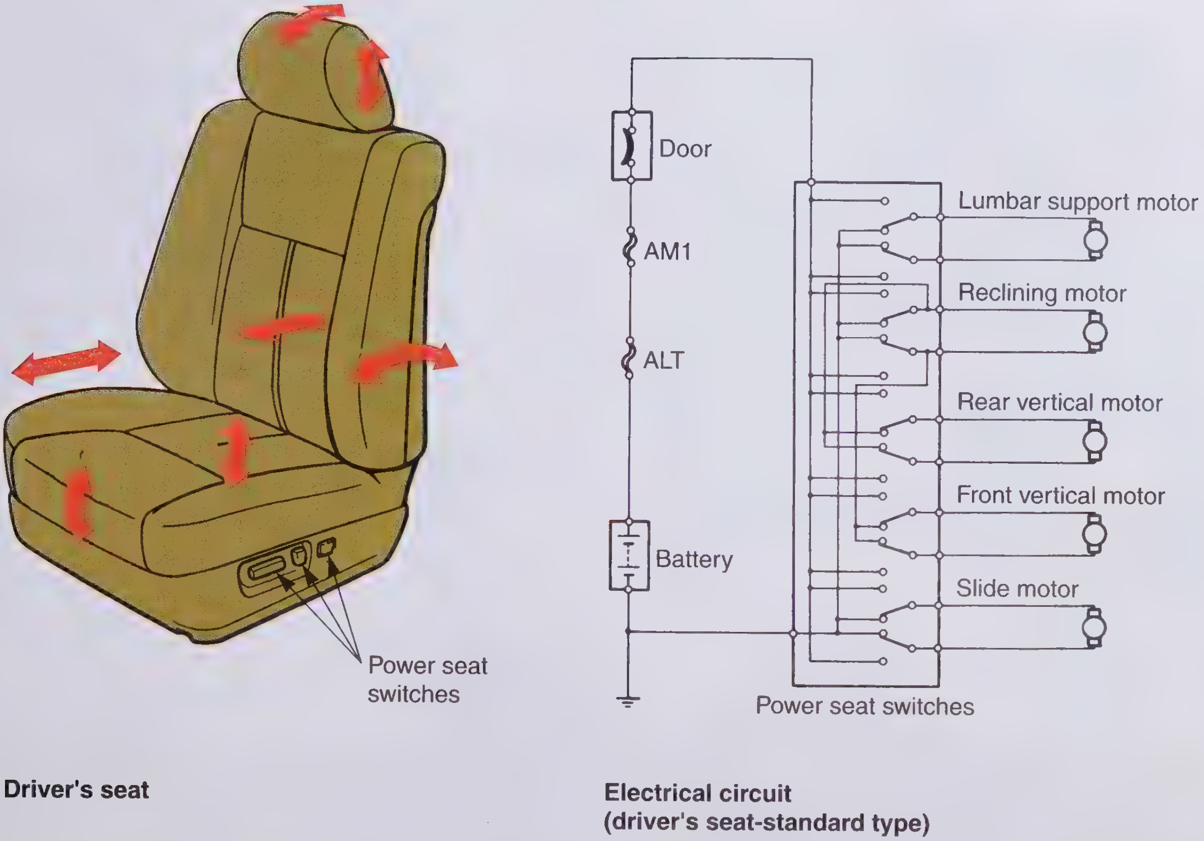
A ***power seat module*** can be programmed to return the seat to a desired position for different drivers. The seat is placed in the desired position and then one of two memory buttons is held down so the module can "remember" the seat location. The next time the memory button is pushed, the module can use the seat sensors and power motors to return the seat to the same location.

Power Seat Service

When diagnosing power seat problems, try to isolate the problem source to a specific area of the circuit. If only one seat fails to work, check parts that affect only that seat. Test its control switch and the wiring between the switch and motors. When the seat only fails in one mode (up and down, for example), check the motor and transmission (gear-cable mechanism) providing that action.



Driver's seat

Electrical circuit (driver's seat-standard type)

Figure 38-15. Note how the wiring diagram shows how switches and each motor operates different seat adjustment. (Lexus)

If both front power seats fail to function, check the common section of the circuit. Inspect the fuse, circuit breakers, wire connections, and any other components affecting both seats.

The most common reasons for power seat problems are the switches and drive motors. Remove and replace any switch or motor that does not work properly. See **Figure 38-17.** If you have difficulty repairing a power seat, read the information in a service manual. It will give directions for servicing the particular unit.

Heated Seats

Heated seats use a heating element (or multiple heating elements), switch, relay, and related wiring to warm the seat cushions in cold weather. Most systems have two large-resistance wires or heating elements routed through the seat cushions. See **Figure 38-18.**

When you press the seat warmer button or switch, it energizes the warmer relay. The relay is a holding relay that stays on once energized. The relay then sends high current through the heating elements, which makes them get warm. The seat warmers stay on until you press an off button or until you shut the ignition switch off.

To service heated seats, check the fuse first. Next, test the warmer switch and then the relay. If you are getting power to the heating element but it does not get hot, the element is probably open and must be replaced.

Power Windows

A ***power window*** uses a control switch, reversible electric motor, circuit breaker, fuse, and related wiring to operate the door windows, **Figure 38-19.**

A small electric ***power window motor*** is located inside each door to operate the ***window regulator*** (up-down mechanism for the glass). The motors have a ***gearbox,*** or ***transmission*** (usually worm and ring gear), that changes the rotating motion of the motor armature into a partial rotation of a larger gear. This action pushes the window open or closed. See **Figure 38-20.**

A circuit breaker protects the window motor from overheating damage. The breaker can open if the switch is held in one position too long. The circuit breaker can be located inside the motor or elsewhere in the circuit. A basic power window circuit is shown in **Figure 38-21.**

Power seat motors
Seat track

Figure 38-17. This seat has been removed to service a power seat motor. If the seat works in all but one position, only service the motor that operates that seat adjustment. (Ford)

Power Window Service

When none of the power windows work, first check the fuse or circuit breaker for the whole system. If only one of the windows is inoperative, use a test light to check for power to its switches and motor.

If you hear a humming sound when a window switch is pressed, the motor gearbox may have stripped gear teeth. The plastic gears in the window motor gearbox can strip after prolonged service. The motor will spin, but movement will not be transferred to the window. If the motor or the switches are found to be bad, they should be replaced.

With hard-to-find problems, refer to the service manual wiring diagram for the power windows. A typical

example is shown in **Figure 38-21.** The circuit will show all the components that could affect power window operation and help with troubleshooting.

Warning!
Be careful because the sheet metal edges on and in doors can cause serious cuts or lacerations. Also, never wear a wristwatch or rings when servicing inside a door. The metal could short across wires or get caught, causing injury or part damage.

Power Door Locks

Power door locks typically use electric switches and solenoids or motors to operate the door lock mechanisms, **Figure 38-22.** When the door key is turned, it closes a switch. A motor or solenoid then moves an arm on the door latch to lock or unlock the door. An additional switch is normally provided on the driver's door panel.

If all the power door locks fail to function, check the main fuse, electrical connections, and other components common to the whole circuit. If only one door lock is bad, check its switch and solenoid or motor. The door lock switches and solenoids are the most common causes of trouble.

Figure 38-23 is a typical power door lock circuit. Study its connections and components.

Figure 38-21. Study this wiring diagram for a typical power window circuit. Note how the electronic control unit operates the driver's window. It causes the window to go all the way down when the button is briefly pushed. The driver can release the switch right away to again grasp the steering wheel. This feature is handy at tollbooths. (Honda)

Door Panel Removal

Door panel removal may be needed to service power windows, seat control switches, door latches, or radio speakers.

The basic procedure for removing a door panel is as follows:

1. Remove all screws that hold the door panel to the door frame. Some are visible; others may be covered with small plastic buttons or covers.
2. Unscrew and remove the door lock button.
3. Remove the inner door handle and window crank, if used.
4. Once all major parts have been removed, you often have to pop out spring clips around the outside of the door panel. Be careful not to bend or tear the panel. Refer to a manual if you have difficulty. See **Figure 38-24.**

Removing trim or door panel

Figure 38-24. Basic procedure for removing a door panel. A—Remove screws from panel and arm rest, if used. Screws may be under pop-off covers or plugs. B—Remove window crank handles. They may be held with screws or you may need to release a special clip from behind the handle, as shown. C—Remove other hardware that is screwed into the body of the door: lock mechanism, lock knob, speaker cover, etc. D—Use a standard screwdriver or a special tool to pop clips out of the door to free the panel. Be careful to pry directly under each clip, or the door panel will tear. (Subaru)

Tech Tip!

The wiring going through the body and into the door can break internally after the door has been opened and closed thousands of times. Keep this in mind when troubleshooting any power device inside or on the door.

Power Trunk Release

A ***power trunk release*** is comprised of a solenoid mounted on the trunk latch, a fuse, a switch, and related wiring. When you close the trunk release switch, it sends power to the solenoid. The solenoid plunger then acts on the trunk latch and the trunk pops open.

Service of this circuit is fairly simple. Most problems are in the switch or solenoid. Use basic testing methods to isolate the problem.

Power Steering Wheel

A ***power steering wheel*** uses a computer and various switches, sensors, and motors to automatically tilt and telescope (extend or retract) the steering wheel. Like memory seats, most systems can be programmed to position themselves automatically. Some are tied to the memory seat circuit and use the same computer.

Figure 38-25 shows a power steering wheel circuit. Study its parts and electrical connections.

Rear Window Defogger

A ***rear window defogger,*** also called a ***rear window defroster,*** commonly uses a switch, a relay, an indicating light, and a window heating grid. See **Figure 38-26.**

When the switch is turned on, it allows current to flow to the indicator light and to the heating grid. The heating grid is resistance wire, usually mounted on or in the window glass. Current flowing through the grid causes the wire to heat up and defog or deice the vehicle's window.

Some rear windows have ***zone clearing defoggers,*** which heat and clear one area before another. Most have higher-resistance wire in the middle to heat and clear the center area of the glass first. They provide for more rapid rearview mirror use. Then, the rest of the window heats and clears.

Figure 38-25. This wiring diagram shows how the ECU can control steering wheel tilt, telescoping action, and the seat belt anchoring motor. Note sensors and switches that feed data to the ECU. Also note the power seat ECU is also networked to this ECU. (Lexus)

A few vehicles use a blower or fan to defog and deice the rear window. Its operation is similar to a heater blower.

Window Defogger Service

When the grid-type rear window defogger does not work, check the fuse first. Then, check for adequate voltage going to the grid with the power switch closed.

If voltage is low at the grid input, test the circuit for opens. If power is being fed to the grid, the grid may be bad. Test the grid as described by the manufacturer. Some allow the repair of a broken heating grid using a special ***grid repair agent,*** which conducts electricity.

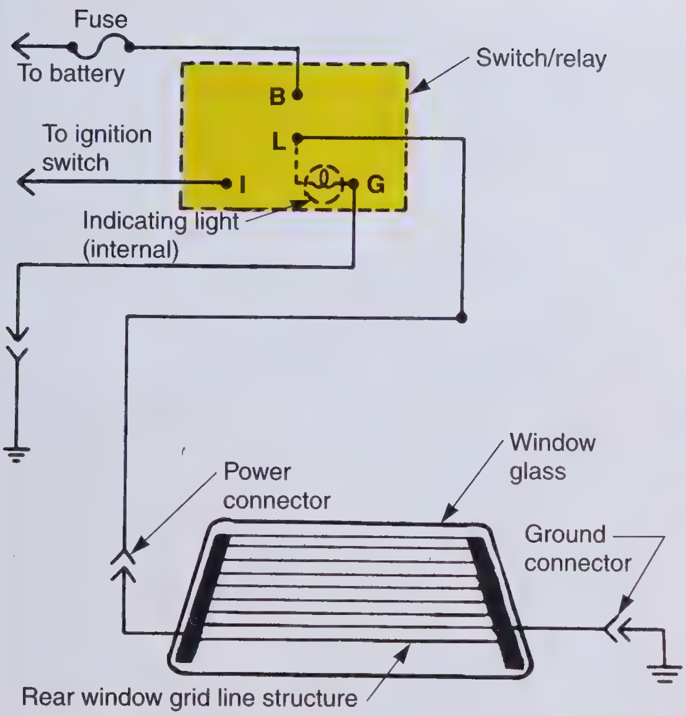

Figure 38-26. This is a circuit for a rear window defogger. When fed current from through a switch and relay, the resistance wire on the glass heats up. (DaimlerChrysler)

Heated Windshield

A ***heated windshield system*** uses a special conductive film sandwiched inside the windshield glass. The transparent film in the windshield glass is usually a zinc and tin oxide material. When high voltage (typically 70–90 volts) is passed through this clear conductive film, the glass heats up and melts ice or snow.

Most systems use a control module to full-field the alternator and bypasses the rest of the electrical system so that enough energy is available to rapidly warm the windshield glass. The other electrical systems operate off of battery voltage when the windshield deicing system is turned on. If the system senses a low battery charge (below 11 volts), the system automatically shuts off to prevent excessive battery discharge.

Warning!
Use caution when working on heated windshield systems. When turned on, there is enough voltage and current to cause a serious electrical shock. Electrocution could result from being shocked by this system's high power output!

Reminder System

A ***reminder system*** (warning system or chime system) makes an audible signal (buzz, chime, or audible warning) if:

- Seat belts are not fastened when the engine is started.
- Keys are left in the ignition with the engine off.
- The headlamps are left on with the engine off and a door is open.

An illustration of a three chime reminder system is shown in **Figure 38-27.** Note how the tone generator can be activated by the seat belts, ignition key, and headlamp switch.

Refer to a service manual when troubleshooting and repairing a reminder system. Numerous design variations are used by different vehicle makers.

Cruise Control Systems

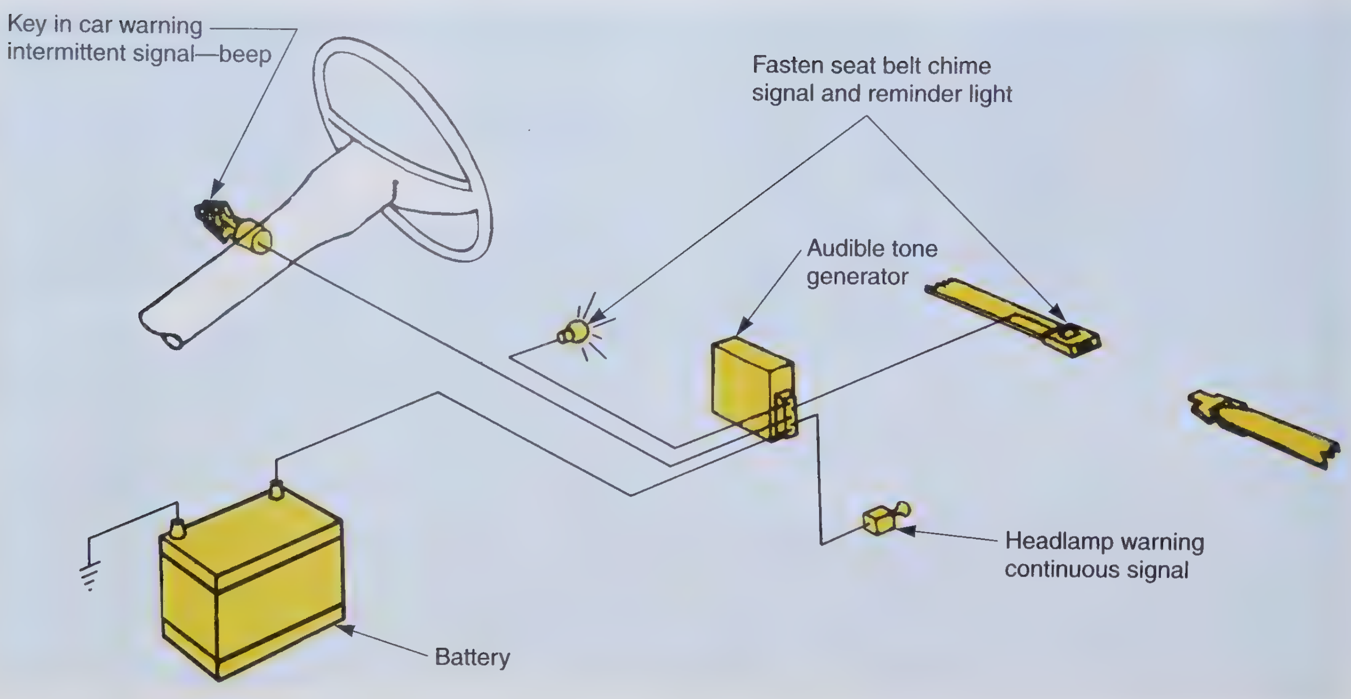
An electronic ***cruise control system*** uses a computer, sensors, and a throttle actuator to maintain vehicle speed for highway driving, **Figure 38-28**. The major parts of a modern cruise control system include:

- ***Power switches*** feed current to computer to activate and ready the system for operation.
- ***Control switch*** signals the computer to maintain present vehicle speed.
- ***Vehicle speed sensor*** feeds pulsing signal into the computer that represents velocity of the vehicle.
- ***Cruise control module*** uses input signals to control outputs to throttle actuator.
- ***Throttle actuator*** physically moves the engine throttle lever to control engine power and resulting vehicle speed.
- ***Brake light switch*** signals the control module to shut off the cruise control when the brakes are applied.
- ***Clutch switch*** signals the control module to deactivate the cruise control when the clutch pedal is depressed.
- ***Neutral safety switch*** signals the control module to shut off the cruise when the shift lever is moved out of drive.

When cruise control system is activated using the power and control switches, the vehicle speed sensor feeds an ac signal to the cruise control module. The module's circuits use this signal to move the throttle actuator back and forth to maintain the same speed or vehicle sensor frequency.

The cruise control senses engine speed and controls the throttle valve opening on the engine. In this way, the driver can set the road speed of the vehicle and the cruise control system will maintain that speed.

For example, if the car starts to go up a hill, the vehicle speed will start to drop. The cruise control



Key in car warning intermittent signal—beep

Battery

Figure 38-27. A warning or reminder system makes a sound when the key is left in the ignition, when seat belts are not fastened, and when lights are left on. Circuit in tone generator is the "heart" and "brain" of the system. (DaimlerChrysler)

module will detect a slower frequency signal from the speed sensor. It can then move the throttle actuator for more engine power to keep the car traveling at the preset speed. The opposite occurs if the car starts down a hill.

When the driver presses on the brakes, the ***brake switch*** deactivates the system. The ***resume switch*** allows the driver to reset the same cruising speed when desired.

Cruise Control System Service

Since cruise control system designs vary so much, only general service methods can be given. Refer to a service manual for details.

If the cruise control will not work at all, check the fuse and power feed wires to the system. Do not forget the simple things. For example, if a brake light switch is shorted on all the time, the cruise control will not engage. The on and resume switches can also wear and fail. Test all simple things before suspecting the control module or actuator.

Figure 38-29 is a typical electronic cruise-control circuit diagram. When troubleshooting, you should study the one for the specific vehicle being repaired.

Figure 38-30 shows a cutaway of a motor-type throttle actuator. It uses a small dc motor and gearbox to move the throttle linkage. Check the motor for normal operation by connecting power to its windings. On older vehicles, the gears may be worn or stripped.

Cruise control module
Connects to throttle linkage
Throttle actuator

Figure 38-28. Layout of an electronic cruise control system. Speed sensors send electrical information to control module. The module can then operate the throttle actuator, which connects to the throttle linkage on the engine. Also note the circuit in the speed control switch. (Ford)
